## **Sir Stanley Davidson (1894–1981)**

This famous textbook was the brainchild of one of the great Professors of Medicine of the 20th century. Stanley Davidson was born in Sri Lanka and began his medical undergraduate training at Trinity College, Cambridge; this was interrupted by World War I and later resumed in Edinburgh. He was seriously wounded in battle, and the carnage and shocking waste of young life that he encountered at that time had a profound effect on his subsequent attitudes and values.

In 1930 Stanley Davidson was appointed Professor of Medicine at the University of Aberdeen, one of the first full-time Chairs of Medicine anywhere and the first in Scotland. In 1938 he took up the Chair of Medicine at Edinburgh and was to remain in this post until retirement in 1959. He was a renowned educator and a particularly gifted teacher at the bedside, where he taught that everything had to be questioned and explained. He personally gave most of the systematic lectures in Medicine, which were made available as typewritten notes that emphasised the essentials and far surpassed any textbook available at the time.

*Principles and Practice of Medicine* was conceived in the late 1940s with its origins in those lecture notes. The first edition, published in 1952, was a masterpiece of clarity and uniformity of style. It was of modest size and price, but sufficiently comprehensive and up to date to provide students with the main elements of sound medical practice. Although the format and presentation have seen many changes in 23 subsequent editions, Sir Stanley's original vision and objectives remain. More than half a century after its first publication, his book continues to inform and educate students, doctors and health professionals all over the world.

# Preface

Well over 2.5 million copies of *Davidson's Principles and Practice of Medicine* have been sold since it was first published in 1952. Now in its 24th Edition, *Davidson's* is regarded as a 'must-have' textbook for thousands of medical students, doctors and health professionals across the world, describing the pathophysiology and clinical features of the most important conditions encountered in the major specialties of adult medicine and explaining how to investigate, diagnose and manage them. The book is the winner of numerous prizes and awards and has been translated into many languages. Taking its origins from Sir Stanley Davidson's much-admired lecture notes, the book has endured because it continues to keep pace with how modern medicine is taught and to provide a wealth of information in an easy-to-read, concise and beautifully illustrated format.

*Davidson's* strives to ensure that readers can not only recognise the clinical features of a disease, but also understand the underlying causes. To achieve this, each chapter begins with a summary of the relevant pre-clinical science, linking pathophysiology with clinical presentation and treatment so that students can use the book from the start of their medical studies right through to their final examinations and beyond.

The regular introduction of new authors and editors is important for maintaining freshness. On this occasion, 21 new authors have joined our existing contributors to make up an outstanding team of authorities in their respective fields. As well as recruiting authors from around the globe, particularly for topics such as infectious diseases, HIV and envenomation, we welcome members from 10 countries on to our International Advisory Board. These leading experts provide detailed comments that are crucial to our revision of each new edition. A particularly important aspect in planning the revision is for the editors to meet students and faculty in medical schools in those countries where the book is most widely read, so that we can respond to the feedback of our global readership and their tutors. We use this feedback, along with the information we gather via detailed student reviews and surveys, to craft each edition. The authors, editors and publishing team aim to ensure that readers all over the world are best served by a book that integrates medical science with clinical medicine to convey key knowledge and practical advice in an accessible and readable format. The amount of detail is tailored to the needs of medical students working towards their final examinations, as well as candidates preparing for Membership of the Royal Colleges of Physicians (MRCP) or its equivalent.

With this new edition we have introduced several changes in both structure and content. The opening eight chapters provide an account of the principles of genetics, immunology, infectious diseases, population health, oncology and pain management, along with a discussion of the core principles behind clinical decision-making and good prescribing.

Subsequent chapters discuss medical emergencies in poisoning, envenomation and medicine in austere environments, while common presentations in acute medicine, including recognition and management of the critically ill patient, are also addressed. The disease-specific chapters that follow cover the major medical specialties, each one thoroughly revised and updated to ensure that readers have access to the 'cutting edge' of medical knowledge and practice. As we publish the 24th edition, the world is in the grip of the COVID-19 pandemic and while our knowledge of virology, epidemiology, clinical impact and management of SARS-CoV-2 is still evolving, we have dedicated a new section on core aspects of this hugely important topic in Chapter 13, but also in Chapter 6 and, as appropriate, elsewhere throughout the book.

The innovations introduced in recent editions have been maintained and, in many cases, developed. The highly popular 'Clinical Examination' overviews have been extended and updated. The 'Presenting Problems' sections continue to provide an invaluable overview of the most common presentations in each disease area. The 'Emergency' and 'Practice Point' boxes have been retained along with the 'In Old Age', 'In Pregnancy' and 'In Adolescence' boxes, which emphasise key practical points in the presentation and management of the older adult, women with medical disorders who are pregnant or planning pregnancy, and adolescents transitioning between paediatric and adult services.

Education is achieved by assimilating information from many sources and readers of this book can enhance their learning experience by using several complementary resources. We developed a self-testing companion book entitled *Davidson's Assessment in Medicine*, containing over 1250 multiple choice questions specifically tailored to the contents of *Davidson's* for the 23rd edition and have added more new online MCQs to accompany this edition. The long-standing association of *Davidson's* with its sister books, *Macleod's Clinical Examination* and *Principles and Practice of Surgery*, still holds good. Our 'family' has also expanded with the publication of *Davidson's Essentials of Medicine*, a pocket-sized version of the main text, now in its 3rd edition; and *Macleod's Clinical Diagnosis*, which describes a systematic approach to the differential diagnosis of symptoms and signs. We congratulate the editors and authors of these books for continuing the tradition of easily digested and expertly illustrated texts.

We all take immense pride in continuing the great tradition first established by Sir Stanley Davidson and in producing an outstanding book for the next generation of doctors.

# Acknowledgements

The editors would like to acknowledge and offer grateful thanks for the input of all previous editions' contributors, without whom this new edition would not have been possible.

In particular we are indebted to those former authors who step down with the arrival of this new edition. They include Quentin M Anstee, Leslie Burnett, Mark Byers, Graham G Dark, Richard J Davenport, Emad El-Omar, David R FitzPatrick, J Alastair Innes, David EJ Jones, Peter Langhorne, John Paul Leach, Sara E Marshall, Rory J McCrimmon, Mairi H McLean, Ewan R Pearson, Peter T Reid, Gordon R Scott, Peter Stewart, John PH Wilding and Miles D Witham.

We are grateful to members of the International Advisory Board, all of whom provided detailed suggestions that have improved the book. Several members have now retired from the Board and we are grateful for their support during the preparation of previous editions. They include Ragavendra Bhat, Khalid I Bzeizi, Piotr Kuna, Pravin Manga, Moffat Nyirenda, Tommy Olsson, KR Sethuraman, Ibrahim Sherif, Ian J Simpson, SG Siva Chidambaram and Josanne Vassallo. We are equally grateful to new members of our International Advisory Board, who have given us valuable advice as we prepared this new edition, including ABM Abdullah, Quazi T Islam, Viswanathan Neelakantan and Jacek Rozanski.

We would like to extend special thanks to Professor Dilip Karnad, Jupiter Hospital, Thane, India, who thoroughly reviewed all chapters of this 24th edition in draft form, to help ensure the coverage of this edition is more relevant than ever to our large readership in India, Pakistan and Bangladesh. He provided invaluable advice to the editorial team during preparation of the 24th edition and exhaustive feedback on how the content aligns with competencies in the current Indian National Medical Commission undergraduate curriculum. Readers of the International Edition of this book can now access a comprehensive Competency Mapping Guide with full page references for the first time as a result of this thorough review.

Detailed chapter reviews were commissioned to help plan this new edition and we are grateful to all those who assisted, including Professor Rustam Al-Shahi, Dr Daniel Beckett, Dr Helen Cohen, Dr Ian Edmond, Dr David Enoch, Professor Tonks Fawcett, Dr Colin Forfar, Professor Richard Gilson, Dr Helena Gleeson, Dr Peter Hall, Dr Greg Heath, Dr Richard Herriot, Dr Robert Lindsay, Dr Catherine Nelson-Piercy and Dr Alex Rowe.

The Editors and Publisher would like to thank all those who have provided valuable feedback on this textbook and whose comments have helped shape this new edition. We would particularly like to extend our thanks to the many readers who contact us with suggestions for improvements. This input has been invaluable and is much appreciated; we regret the names are too numerous to mention individually.

The authors of Chapter 20 would like to thank Dr Drew Henderson, who reviewed the 'Diabetic nephropathy' section, and we are indebted to Dr Ruth Darbyshire for assistance with the Ophthalmology multiple choice questions to accompany Chapter 30.

Two short sections in Chapter 3 on array comparative genomic hybridisation and single-molecule sequencing are adapted from Dr K Tatton-Brown's Massive Open Online Course for FutureLearn. We would like to thank the Open University and St George's, University of London, for permission to use this material.

We are especially grateful to Laurence Hunter and Wendy Lee from Elsevier for their endless support and expertise in the shaping, collation and publication of Davidson's over many years and who have now retired. We have thoroughly enjoyed working with a new team including Jeremy Bowes, Siân Jarman and Anne Collett who have seamlessly taken over the reins. We are delighted that Robert Britton continues to work on the book and illustrate it beautifully. We are proud of this new edition and are confident it will remain an essential and invaluable resource for readers the world over.

FCPS Single Best Question

# Introduction

The opening chapters of the book, making up Part 1 on 'Fundamentals of Medicine', provide an account of the principles of genetics, immunology, infectious diseases and population health, oncology and pain management, along with a discussion of the core principles behind clinical decision-making and good prescribing. Subsequent chapters in Part 2, 'Emergency and Critical Care Medicine', discuss medical emergencies in poisoning, envenomation and medicine in austere environments, while [Chapter 9](#) explores common presentations in acute medicine, as well as the recognition and management of the critically ill. The third part, 'Clinical Medicine', is devoted to the major medical specialties. Each chapter has been written by experts in the field to provide the level of detail expected of trainees in their discipline. To maintain the book's virtue of being concise, care has been taken to avoid unnecessary duplication between chapters.

The system-based chapters in Part 3 follow a standard format, beginning with an overview of the relevant aspects of clinical examination, followed by an account of functional anatomy, physiology and investigations, then the common presentations of disease, and details of the individual diseases and treatments relevant to that system. In chapters that describe the immunological, cellular and molecular basis of disease, this problem-based approach brings the close links between modern medical science and clinical practice into sharp focus.

The methods used to present information are described below.

## Clinical examination overviews

The value of good clinical skills is highlighted by a two-page overview of the important elements of the clinical examination at the beginning of most chapters. The left-hand page includes a mannikin to illustrate key steps in examination of the relevant system, beginning with simple observations and progressing in a logical sequence around the body. The right-hand page expands on selected themes and includes tips on examination technique and interpretation of physical signs. These overviews are intended to act as an aide-mémoire and not as a replacement for a detailed text on clinical examination, as provided in our sister title, *Macleod's Clinical Examination*.

## Presenting problems

Medical students and junior doctors must not only assimilate a great many facts about various disorders, but also develop an analytical approach to formulating a differential diagnosis and a plan of investigation for patients who present with particular symptoms or signs. In *Davidson's* this is addressed by incorporating a 'Presenting Problems' section into all relevant chapters. Nearly 250 presentations are included, which represent the most common reasons for referral to each medical specialty.

## Boxes

Boxes are a popular way of presenting information and are particularly useful for revision. They are classified by the type of information they contain, using specific symbols.

### General Information

These include causes, clinical features, investigations, treatments and other useful information.

### Practice Point

There are many practical skills that students and doctors must master. These vary from inserting a nasogastric tube to reading an ECG or X-ray, or interpreting investigations such as arterial blood gases or thyroid function tests. 'Practice Point' boxes provide straightforward guidance on how these and many other skills can be acquired and applied.

### Emergency

These boxes describe the management of many of the most common emergencies in medicine.

### In Old Age

Life expectancy is increasing in many countries and older people are the chief users of health care. While they contract the same diseases as those who are younger, there are often important differences in the way they present and how they are best managed. [Chapter 34](#), 'Ageing and disease', concentrates on the principles of managing the frailest group, who suffer from multiple comorbidity and disability, and who tend to present with non-specific problems such as falls or delirium. Many older people, though, also suffer from specific single-organ pathology. 'In Old Age' boxes are thus included in each chapter and describe common presentations, implications of physiological changes of ageing, effects of age on investigations, problems of treatment in old age, and the benefits and risks of intervention in older people.

### In Pregnancy

Many conditions are different in the context of pregnancy, while some arise only during or shortly after pregnancy. Particular care must be taken with investigations (for example, to avoid radiation exposure to the fetus) and treatment (to avoid the use of drugs that harm the fetus). These issues are highlighted by 'In Pregnancy' boxes distributed throughout the book, which complement [Chapter 32](#), 'Maternal medicine'.

### ***In Adolescence***

Although paediatric medicine is not covered in *Davidson's*, many chronic disorders begin in childhood, and physicians who look after adults often contribute to multidisciplinary teams that manage young patients 'in transition' between paediatric and adult health-care services. This group of patients often presents a particular challenge, due to the physiological and psychological changes that occur in adolescence, and which can have a major impact on the disease and its management. Adolescents can be encouraged to take over responsibility from their parents/carers in managing their disease, but are naturally rebellious and often struggle to adhere to the impositions of chronic treatment. [Chapter 33](#), 'Adolescent and transition medicine', highlights these issues, alongside the 'In Adolescence' boxes that appear in relevant chapters.

### **Terminology**

The recommended International Non-proprietary Names (INNs) are used for all drugs, with the exception of adrenaline and noradrenaline. British spellings have been retained for drug classes and groups (e.g. amphetamines not amfetamines).

### **Units of measurement**

The International System of Units (SI units) is the recommended means of presentation for laboratory data and has been used throughout *Davidson's*. We recognise, however, that many laboratories around

the world continue to provide data in non-SI units, so these have been included in the text for the commonly measured analytes. Both SI and non-SI units are also given in [Chapter 35](#), which describes the reference ranges used in laboratories in Edinburgh. It is important to appreciate that these reference ranges may vary from those used in other laboratories.

### **Finding what you are looking for**

A contents list is given on the opening page of each chapter. In addition, the book contains cross-references to help readers find their way around, along with an extensive index. A list of up-to-date reviews and useful websites with links to management guidelines appears at the end of each chapter.

### ***Giving us your feedback***

The Editors and Publisher hope that you will find this edition of *Davidson's* informative and easy to use. We would be delighted to hear from you if you have any comments or suggestions to make for future editions of the book. Please contact us by e-mail at: [davidson.feedback@elsevier.com](mailto:davidson.feedback@elsevier.com). All comments received will be much appreciated and will be considered by the editorial team.

## Answers to problems 11

## Introduction

A great deal of knowledge and skill is required to practise as a doctor. Physicians in the 21st century need to have a comprehensive knowledge of basic and clinical sciences, have good communication skills, be able to perform procedures, work effectively in a team and demonstrate professional and ethical behaviour. But how doctors think, reason and make decisions is arguably their most critical skill. Knowledge is necessary, but not sufficient on its own for good performance and safe care. This chapter describes the principles of clinical decision-making, also known as 'clinical reasoning'.

## The problem of diagnostic error

It is estimated that diagnosis is wrong 10%–15% of the time in specialties such as emergency medicine, internal medicine and general practice. Diagnostic error is associated with greater morbidity than other types of medical error, and the majority is considered to be preventable. For every diagnostic error there are usually several root causes. Studies identify three main categories, shown in Box 1.1. However, 'human cognitive error' appears to play a significant role in the majority of diagnostic errors.

Human cognitive error occurs when the clinician has all the information necessary to make the diagnosis, but then makes the wrong diagnosis. Why does this happen? Three main reasons have been identified:

- knowledge gaps
- misinterpretation of diagnostic tests
- cognitive biases.

Examples of errors in these three categories are shown in Box 1.2. Clearly, clinical knowledge is required for sound clinical reasoning, and an incomplete knowledge base or inadequate experience can lead to diagnostic error. However, this chapter will focus on some other aspects of knowledge that are important for effective clinical reasoning, including use and interpretation of diagnostic tests, cognitive biases and human factors.

## Clinical reasoning: definitions

'Clinical reasoning' describes the thinking and decision-making processes associated with clinical practice. Our understanding of clinical reasoning derives from the fields of education, cognitive psychology, studies of expertise and the diagnostic error and health systems literature.

Clinical reasoning can be conceptualised as a process with different components, each requiring specific knowledge, skills and behaviours.

1.1 Root causes of diagnostic error in studies	
Error category	Examples
No fault	Unusual presentation of a disease Missing information
System error	Inadequate diagnostic support Results not available Error-prone processes Poor supervision of inexperienced staff Poor team communication
Human cognitive error	Inadequate data-gathering Errors in reasoning

*Adapted from Graber M, Gordon R, Franklin N. Reducing diagnostic errors in medicine: what is the goal? Acad Med 2002; 77:981–992.*

1.2 Reasons for errors in clinical reasoning	
Source of error	Examples
Knowledge gaps	Telling a patient she cannot have biliary colic because she has had her gallbladder removed – gallstones can form in the bile ducts in patients who have had a cholecystectomy
Misinterpretation of diagnostic tests	Deciding a patient has not had a stroke because his brain scan is normal – computed tomography and even magnetic resonance imaging, especially when performed early, may not identify an infarct
Cognitive biases	Accepting a diagnosis handed over to you without question (the 'framing effect') instead of asking yourself 'What is the evidence that supports this diagnosis?'

The UK Clinical Reasoning in Medical Education group (see 'Further information') broadly lists these components as:

- history and physical examination
- use and interpretation of diagnostic tests
- problem identification and management
- shared decision-making.

Not all of these components are necessary for effective clinical reasoning and they do not necessarily happen in this order. They also occur in contexts that impact on decision-making, which will be explored later. Underpinning all of this is formal and experiential knowledge of basic sciences and clinical medicine. The knowledge required for effective clinical reasoning includes factual knowledge, but also conceptual knowledge (how things fit together) as well as procedural knowledge (how to do something, what techniques to use) plus an awareness of and an ability to think about one's own thinking (also known as metacognitive knowledge). This is where an understanding of cognitive biases and human factors is important.

Fig. 1.1 shows the key components involved in clinical reasoning that will be explored further in this chapter.

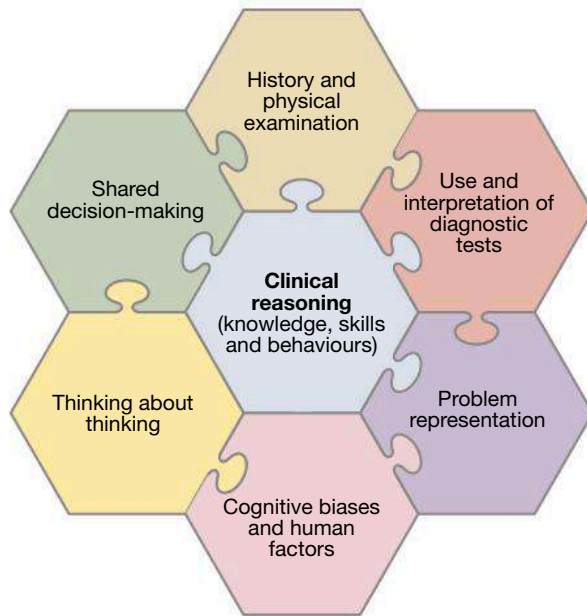

## History and physical examination

Even with major advances in medical technology, the history remains the most important part of the clinical decision-making process. Studies show that physicians make a diagnosis in 70%–90% of cases from the history alone. It is important to remember that the history is explored not only with the patient, but also (and with consent if required) from all available sources if necessary: for example, paramedic and emergency department notes, eye-witnesses, relatives and/or carers.

However, clinicians need to be aware of the diagnostic usefulness of clinical features in the history and physical examination. For example, students are often taught that meningitis classically presents with the following features:

- headache
- fever
- meningism (photophobia, neck stiffness and other signs of meningeal irritation, such as Kernig's and Brudzinski's signs).

However, knowing the frequency with which patients present with certain features and the diagnostic weight of each feature are important in clinical decision-making. Many patients with meningitis do not

**Fig. 1.1** Elements of clinical reasoning.

have classical signs of meningism and the clinical presentation varies among different patient populations and in different parts of the world. In one prospective study conducted in the United States, nearly all adult patients with meningitis had headache and a fever, but less than half had neck stiffness on examination and only 5% of patients had Kernig's and Brudzinski's signs. All three signs had a likelihood ratio of around 1, meaning their presence or absence was of little use in deciding whether a patient had meningitis or not (Fig. 1.2).

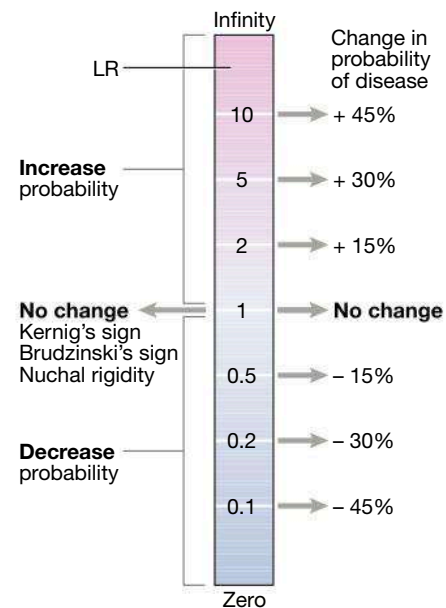

Likelihood ratios (LR) are clinical diagnostic weights. An LR of greater than 1 increases the probability of disease (the higher the value, the greater the probability). Similarly, an LR of less than 1 decreases the probability of disease. LRs are developed against a diagnostic standard (in the case of meningitis, lumbar puncture results), so do not exist for all clinical findings. LRs illustrate how an individual clinical finding changes the probability of a disease. For example, in a person presenting with headache and fever, the clinical finding of neck stiffness may carry little weight in deciding whether to perform a lumbar puncture because LRs do not determine the prior probability of disease; they reflect only how a single clinical finding changes it. Clinicians have to take all the available information from the history and physical examination into account. If the overall clinical probability is high to begin with, a clinical finding with an LR of around 1 does not change this.

'Evidence-based history and examination' is a term used to describe how clinicians incorporate knowledge about the prevalence and diagnostic weight of clinical findings into their decision-making. In studies, students who are taught the probabilities of features being present in specific diseases rather than lists of features have better diagnostic accuracy. This is improved further by understanding the basic science explanation for symptoms and signs: bedside signs of meningism identify patients with severe meningeal inflammation but do not pick up those with early or mild inflammation.

Evidence-based history and examination is important because estimating the clinical (pre-test) probability is vital not only for diagnostic accuracy, but also in the use and interpretation of diagnostic tests.

## Use and interpretation of diagnostic tests

There is no such thing as a perfect diagnostic test. Test results give us test probabilities, not real probabilities. Test results have to be interpreted because they are affected by the following:

**Fig. 1.2** Likelihood ratio (LR) of Kernig's sign, Brudzinski's sign and nuchal rigidity in the clinical diagnosis of meningitis.

$$\text{LR} = \frac{\text{probability of finding in patients with disease}}{\text{probability of finding in patients without disease}}$$

LRs are also used for diagnostic tests; here a physical examination finding can be considered a diagnostic test. *Data from Thomas KE, Hasbun R, Jekel J, et al. The diagnostic accuracy of Kernig's sign, Brudzinski's sign, and nuchal rigidity in adults with suspected meningitis. Clin Infect Dis 2002; 35:46–52.*

- how 'normal' is defined
- factors other than disease
- operating characteristics
- sensitivity and specificity
- prevalence of disease in the population.

## Normal values

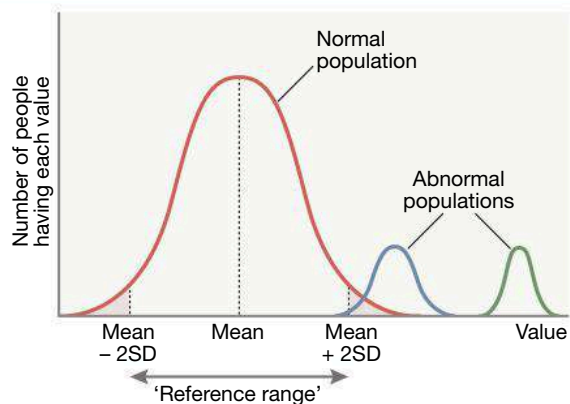

Most tests provide quantitative results (i.e. a value on a continuous numerical scale). In order to classify quantitative results as normal or abnormal, it is necessary to define a cut-off point. Many quantitative measurements in populations have a Gaussian or 'normal' distribution. By convention, the normal range is defined as those values that encompass 95% of the population, or 2 standard deviations above and below the mean. This means that 2.5% of the normal population will have values above, and 2.5% will have values below the normal range. For this reason, it is more appropriate to talk about the 'reference range' rather than the 'normal range' (Fig. 1.3).

Test results in abnormal populations also have a Gaussian distribution, with a different mean and standard deviation. In some diseases there is no overlap between results from the abnormal and normal population. However, in many diseases there is overlap; in these circumstances, the greater the difference between the test result and the limits of the reference range, the higher the chance that the person has the disease.

However, there are also situations in medicine when 'normal' is abnormal and 'abnormal' is normal. For example, in the context of a severe asthma attack a 'normal'  $\text{PaCO}_2$  is abnormal and means the patient has life-threatening asthma. Conversely, a low ferritin in a young menstruating woman is not considered to be abnormal at all.

Laboratory results (e.g. cholesterol, thyroid-stimulating hormone) also vary from day to day in the same person in the absence of a real change because of biological variation and laboratory variation. The extent to which a blood test is allowed to vary before it has truly changed is called

**Fig. 1.3 Normal distribution and reference range.** For many tests, the frequency distribution of results in the normal healthy population (red line) is a symmetrical bell-shaped curve. The mean  $\pm 2$  standard deviations (SD) encompasses 95% of the normal population and usually defines the 'reference range'; 2.5% of the normal population have values above, and 2.5% below, this range (shaded areas). For some diseases (blue line), test results overlap with the normal population or even with the reference range. For other diseases (green line), tests may be more reliable because there is no overlap between the normal and abnormal population.

the 'critical difference'. The critical difference is different for each test, and can be high – 17% in the case of cholesterol and higher for some other tests.

### Factors other than disease that influence test results

A number of factors other than disease influence test results:

- age
- ethnicity
- pregnancy
- sex
- spurious (in vitro) results.

Box 1.3 gives some examples.

### Operating characteristics

Tests are also subject to operating characteristics. This refers to the way the test is performed. Patients need to be able to comply fully with some tests, such as spirometry (p. 501), and if they cannot, the test result will be affected. Some tests are very dependent on the skill of the operator and are also affected by the patient's body habitus and clinical state; ultrasound of the heart and abdomen are examples. A common mistake is when doctors refer to a test result as 'no abnormality detected' when, in fact, the report describes a technically difficult and incomplete scan that should more accurately be described as 'non-diagnostic'.

Some conditions are paroxysmal. For example, around half of patients with epilepsy have a normal standard electroencephalogram (EEG). A normal EEG therefore does not exclude epilepsy. On the other hand, around 10% of patients who do *not* have epilepsy have epileptiform discharges on their EEG. This is referred to as an 'incidental finding'. Incidental findings are common in medicine, and are increasing in incidence with the greater availability of more sensitive tests. Test results should always be interpreted in the light of the patient's history and physical examination.

### Sensitivity and specificity

Diagnostic tests have characteristics termed 'sensitivity' and 'specificity'. Sensitivity is the ability to detect true positives; specificity is the ability to

### i

### 1.3 Examples of factors other than disease that influence test results

Factor	Examples
<b>Age</b>	Creatinine is lower in old age (due to relatively lower muscle mass) – an older person can have a significantly reduced eGFR with a 'normal' creatinine
<b>Ethnicity</b>	Healthy people of African ancestry have lower white cell counts
<b>Pregnancy</b>	Several tests are affected by late pregnancy, due to the effects of a growing fetus, including: Reduced urea and creatinine (haemodilution) Iron deficiency anaemia (increased demand) Increased alkaline phosphatase (produced by the placenta) Raised D-dimer (physiological changes in the coagulation system) Mild respiratory alkalosis (physiological maternal hyperventilation) ECG changes (tachycardia, left axis deviation)
<b>Sex</b>	Males and females have different reference ranges for many tests, e.g. haemoglobin
<b>Spurious (in vitro) results</b>	A spurious high potassium is seen in haemolysis and in thrombocytosis ('pseudohyperkalaemia')

(ECG = electrocardiogram; eGFR = estimated glomerular filtration rate, a better estimate of renal function than creatinine)

detect true negatives. Even a very good test, with 95% sensitivity, will miss 1 in 20 people with the disease. Every test therefore generates 'false positives' and 'false negatives' (Box 1.4).

A very sensitive test will detect most disease but may generate abnormal findings in healthy people. A negative result will therefore reliably exclude disease but a positive result does not mean the disease is present – it means further evaluation is required. On the other hand, a very specific test may miss significant pathology but is likely to establish the diagnosis beyond doubt when the result is positive. All tests differ in their sensitivity and specificity, and clinicians require a working knowledge of the tests they use in order to accurately interpret them.

In choosing how a test is used to guide decision-making there is a trade-off between sensitivity versus specificity. For example, defining an exercise electrocardiogram (p. 393) as abnormal if there is at least 0.5 mm of ST depression would ensure that very few cases of coronary artery disease are missed but would generate many false-positive results (high sensitivity, low specificity). On the other hand, a cut-off point of 2.0 mm of ST depression would detect most cases of important coronary artery disease with far fewer false positives. This trade-off is calculated using the receiver operating characteristic curve of the test (Fig. 1.4).

An extremely important concept in clinical decision-making is this: the probability that a person has a disease depends on the pre-test probability, and the sensitivity and specificity of the test. For example, imagine an older woman has fallen and hurt her left hip. On examination, the hip is extremely painful to move and she cannot stand. However, her hip X-rays are normal. Does she have a fracture?

The sensitivity of plain X-rays of the hip performed in the emergency department for suspected hip fracture is around 95%. A small percentage of fractures are therefore missed. If our patient has (or is at risk of) osteoporosis, has severe pain on hip movement and cannot bear weight on the affected side, then the clinical probability of hip fracture is high. If, on the other hand, she is unlikely to have osteoporosis, has no pain on

1.4 Sensitivity and specificity		
	Disease	No disease
Positive test	A (True positive)	B (False positive)
Negative test	C (False negative)	D (True negative)
Sensitivity = $A/(A+C) \times 100$		
Specificity = $D/(D+B) \times 100$		

**Fig. 1.4** Receiver operating characteristic graph illustrating the trade-off between sensitivity and specificity for a given test. The curve is generated by ‘adjusting’ the cut-off values defining normal and abnormal results, calculating the effect on sensitivity and specificity and then plotting these against each other. The closer the curve lies to the top left-hand corner, the more useful the test. The red line illustrates a test with useful discriminant value and the green line illustrates a less useful, poorly discriminant test.

hip movement and is able to bear weight, then the clinical probability of hip fracture is low.

Doctors are continually making judgements about whether something is true, given that something else is true. This is known as ‘conditional probability’. Bayes’ Theorem (named after English clergyman Thomas Bayes, 1702–1761) is a mathematical way to describe the post-test probability of a disease by combining pre-test probability, sensitivity and specificity. In clinical practice, doctors are not able to make complex mathematical calculations for every decision they make. In practical terms, the answer to the question of whether there is a fracture is that in a high-probability patient a normal test result does not exclude it, but in a low-probability patient it (virtually) does. This principle is illustrated in Fig. 1.5.

Sox and colleagues (see ‘Further information’) state a fundamental assertion, which they describe as a profound and subtle principle of clinical medicine: the interpretation of new information depends on what you believed beforehand. In other words, the interpretation of a test result depends on the probability of disease before the test.

## Prevalence of disease

Consider this problem that was posed to a group of Harvard doctors. The problem originates from a 1978 article in the *New England Journal of Medicine* (Casscells et al, see ‘Further information’): if a test to detect a disease whose prevalence is 1:1000 has a false-positive rate of 5%, what is the chance that a person found to have a positive result actually has the disease, assuming you know nothing about the person’s symptoms and signs? Assume the test generates no false negatives and take a moment to work this out. In this problem, we have removed clinical probability and are only considering prevalence. The answer is at the end of the chapter (p. 11).

Predictive values combine sensitivity, specificity and prevalence. Sensitivity and specificity are characteristics of the test; the population

does not change this. However, as doctors, we are interested in the question, ‘What is the probability that a person with a positive test actually has the disease?’ This is illustrated in Box 1.5.

Post-test probability and predictive values are different. Post-test probability is the probability of a disease after taking into account new information from a test result. Bayes’ Theorem can be used to calculate post-test probability for a patient in any population. The pre-test probability of disease is decided by the doctor; it is a judgement based on information gathered prior to ordering the test. Predictive value is the proportion of patients with a test result who have the disease (or no disease) and is calculated from a table of results in a specific population (see Box 1.5). It is not possible to transfer this value to a different population. This is important to realise because published information about the performance of diagnostic tests may not apply to different populations.

In deciding the pre-test probability of disease, clinicians often neglect to take prevalence into account and this distorts their estimate of probability. To estimate the probability of disease in a patient more accurately, clinicians should anchor on the prevalence of disease in the subgroup to which the patient belongs and then adjust to take the individual factors into account.

## Dealing with uncertainty

Clinical findings are imperfect and diagnostic tests are imperfect. It is important to recognise that clinicians frequently deal with uncertainty. By expressing uncertainty as probability, new information from diagnostic tests can be incorporated more accurately. However, subjective estimates of probability can sometimes be unreliable. As the section on cognitive biases will demonstrate (see below), intuition can be a source of error.

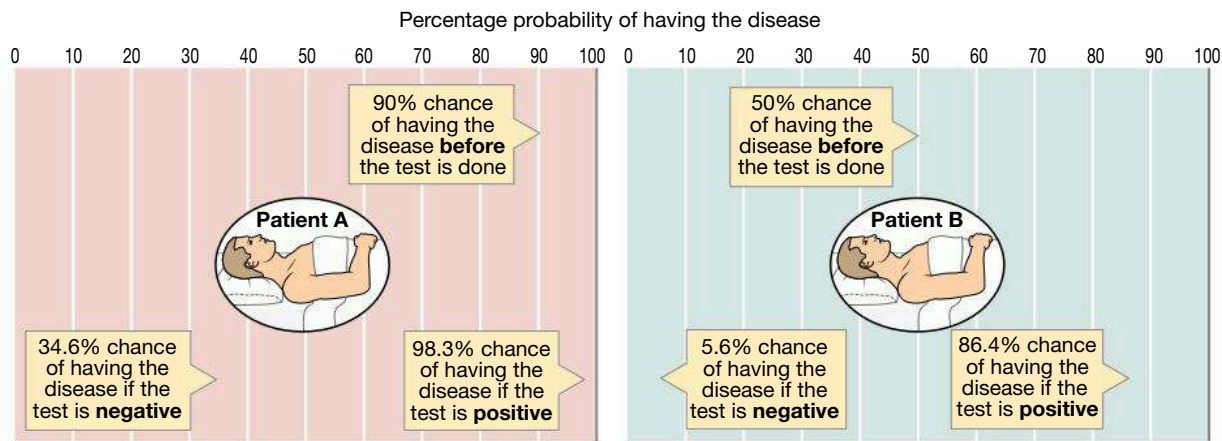

Knowing the patient’s true state is often unnecessary in clinical decision-making. Sox and colleagues (see ‘Further information’) argue that there is a difference between knowing that a disease is present and acting as if it were present. The requirement for diagnostic certainty depends on the penalty for being wrong. Different situations require different levels of certainty before starting treatment. How we communicate uncertainty to patients will be discussed later in this chapter (see Fig. 1.9).

The ‘treatment threshold’ combines factors such as the risks of the test, and the risks versus benefits of treatment. The point at which the factors are all evenly weighed is the threshold. If a test or treatment for a disease is effective and low risk (e.g. giving antibiotics for a suspected urinary tract infection), then there is a lower threshold for going ahead. On the other hand, if a test or treatment is less effective or high risk (e.g. starting chemotherapy for a malignant brain tumour), then greater confidence is required in the clinical diagnosis and potential benefits of treatment first. In principle, if a diagnostic test will not change the management of the patient, then careful consideration should be given to whether it is necessary to do the test at all.

In summary, test results shift our thinking, but rarely give a ‘yes’ or a ‘no’ answer in terms of a diagnosis. Sometimes tests shift the probability of disease by less than we realise. Pre-test probability is key, and this is derived from the history and physical examination, combined with a sound knowledge of medicine and an understanding of the prevalence of disease in the particular care setting or the population to which the patient belongs.

## Problem representation

Many students are taught to formulate a differential diagnosis after the history, physical examination and initial test results, but the ability to accurately articulate a ‘problem representation’ (or problem list) first and *then* construct a prioritised differential diagnosis based on this, including relevant ‘must-not-miss’ diagnoses, is a key step in the clinical reasoning process. A problem representation refers to how information about a problem is mentally organised. Studies show that expert clinicians spend far more time on defining a problem before trying to solve it compared with novices, and novices are more likely to be unsuccessful in solving

**Fig. 1.5** The interpretation of a test result depends on the probability of the disease before the test is carried out. In the example shown, the test being carried out has a sensitivity of 95% and a specificity of 85%. Patient A has very characteristic clinical findings, which make the pre-test probability of the condition for which the test is being used very high – estimated as 90%. Patient B has more equivocal findings, such that the pre-test probability is estimated as only 50%. If the result in Patient A is negative, there is still a significant chance that he has the condition for which he is being tested; in Patient B, however, a negative result makes the diagnosis very unlikely.

	Disease	No disease
<b>Positive test</b>	A (True positive)	B (False positive)
<b>Negative test</b>	C (False negative)	D (True negative)
Positive predictive value = $A/(A+B) \times 100$		
Negative predictive value = $D/(D+C) \times 100$		

a problem because they have not accurately represented the problem in the first place. The ability to synthesise all the available information and encapsulate it into a problem representation using precise medical language is an important skill that helps to organise and retrieve knowledge from long-term memory relevant to the case and is associated with significantly higher diagnostic accuracy, particularly in complex cases (Bordage, 1994; see 'Further information').

Formulating a problem representation (e.g. a 30-year-old pregnant woman with acute left-sided pleuritic chest pain and breathlessness) or a problem list (e.g. persistent vomiting, hypokalaemia, acute kidney injury), not only helps to organise and retrieve knowledge relevant to the case which helps in diagnosis, it also helps to formulate an action plan while further information is being gathered when a diagnosis is not yet possible.

## Cognitive biases

Advances in cognitive psychology in recent decades have demonstrated that human thinking and decision-making are prone to error. Cognitive biases are subconscious errors that lead to inaccurate judgement and illogical interpretation of information. They are prevalent in everyday life; as the famous saying goes, 'to err is human'.

Take a few moments to look at this simple puzzle. Do not try to solve it mathematically but listen to your intuition:

- A bat and ball cost £1.10.
- The bat costs £1 more than the ball.
- How much does the ball cost?

The answer is at the end of the chapter. Most people get the answer to this puzzle wrong – even though they have all the knowledge and experience they need to solve this problem. Why? British psychologist and patient safety pioneer James Reason said that, 'Our propensity

for certain types of error is the price we pay for the brain's remarkable ability to think and act intuitively – to sift quickly through the sensory information that constantly bombards us without wasting time trying to work through every situation anew.' This property of human thinking is highly relevant to clinical decision-making.

## Type 1 and type 2 thinking

Decades of studies in cognitive psychology and, more recently, functional magnetic resonance imaging demonstrate two distinct types of processes when it comes to decision-making: humans have a fast, intuitive, pattern-recognising way of thinking which uses little cognitive effort (known as type 1 thinking) and a more deliberate, analytical one which engages our working memory (known as type 2 thinking). This is known as 'dual process theory' and Box 1.6 explains this in more detail.

Psychologists estimate that we spend 95% of our daily lives engaged in type 1 thinking – the intuitive, fast, subconscious mode of decision-making. Imagine driving a car, for example: it would be impossible to function efficiently if every decision and movement were as deliberate, conscious, slow and effortful as in our first driving lesson. With experience, complex procedures become automatic, fast and effortless. The same applies to medical practice. There is evidence that expert decision-making is well served by intuitive thinking. The problem is that although intuitive processing is highly efficient in many circumstances, in others it is prone to error.

Clinicians use both type 1 and type 2 thinking, and both types are important in clinical decision-making. When encountering a problem that is familiar, clinicians employ pattern recognition and reach a working diagnosis or differential diagnosis quickly (type 1 thinking). When encountering a problem that is more complicated, they use a slower, systematic approach (type 2 thinking). Both types of thinking interplay – they are not mutually exclusive in the diagnostic process. Fig. 1.6 illustrates the interplay between type 1 and type 2 thinking in clinical practice.

Errors can occur in both type 1 and type 2 thinking. For example, people can apply the wrong rules or make errors in their application while using type 2 thinking. However, it has been argued that the common cognitive biases encountered in medicine tend to occur when clinicians are engaged in type 1 thinking.

For example, imagine being asked to see a young woman who is drowsy. She is handed over to you as a 'probable overdose' because she has a history of depression and a packet of painkillers was found beside her at home. Her observations show she has a Glasgow Coma Scale score of 10/15, heart rate 100 beats/min, blood pressure 100/60 mmHg, respiratory rate 14 breaths/min, oxygen saturations 98% on air and temperature 37.5°C. Already your mind has reached a working diagnosis. It fits a pattern (type 1 thinking). You think she has taken an overdose. At

1.6 Type 1 and type 2 thinking	
Type 1	Type 2
Intuitive, heuristic (pattern recognition)	Analytical, systematic
Automatic, subconscious	Deliberate, conscious
Fast, effortless	Slow, effortful
Low/variable reliability	High/consistent reliability
Vulnerable to error	Less prone to error
Highly affected by context	Less affected by context
High emotional involvement	Low emotional involvement
Low scientific rigour	High scientific rigour

this point you can stop to think about your thinking (rational override in Fig. 1.6): ‘What is the evidence for this diagnosis? What else could it be?’

On the other hand, imagine being asked to assess a patient who has been admitted with syncope. There are several different causes of syncope and a systematic approach is required to reach a diagnosis (type 2 thinking). However, you recently heard about a case of syncope due to a painless leaking abdominal aortic aneurysm. At the end of your assessment, following evidence-based guidelines, it is clear the patient can be discharged. Despite this, you decide to observe the patient overnight *just in case* (irrational override in Fig. 1.6). In this example, your intuition is actually ‘availability bias’ (when things are at the forefront of your mind) which has significantly distorted your estimate of probability.

### Common cognitive biases in medicine

Figure 1.7 illustrates the common cognitive biases prevalent in medical practice. Biases often work together; for example, in overconfidence bias (the tendency to believe we know more than we actually do), too much faith is placed in opinion instead of gathered evidence. This bias can be augmented by the availability bias and finally by commission bias (the tendency towards action rather than inaction) – sometimes with disastrous results.

The mark of a well-calibrated thinker is the ability to recognise what mode of thinking is being employed and to anticipate and recognise situations in which cognitive biases and errors are more likely to occur.

### Thinking about thinking

Research has highlighted the importance of being aware of and being able to think about one’s own thinking (also known as metacognition). Several studies have demonstrated that engaging in reflection during diagnostic decision-making improves performance (Prakash et al, see ‘Further information’). This can be as simple as asking, ‘What is the evidence for this diagnosis? What else could it be?’ Reflection is most effective when the case is more complex (relative to the clinician).

Some people have a natural tendency to look for evidence, weigh things up, be aware of context, not take things at face value, and think about their own thinking. Others can learn to do so. Psychologists consider this ‘reflective mind’ a subset of analytical type 2 thinking. The tendency to engage in reflection during decision-making is independent of knowledge and cognitive ability, and accounts for the greatest variation in individual performance on many reasoning tasks.

With increasing knowledge and experience, intuitive type 1 thinking is used more; it is fast and highly accurate and commonly used by experts. Novices cannot do this because they have not yet built a database of patterns in their long-term memory, known as illness scripts. Reflection interrupts type 1 processing, even briefly, to simulate alternatives. So as you can see, good decision-making relies on knowledge and experience, but also the ability to ‘stop and think’ when needed. However, this requires cognitive effort (type 2 thinking), which may be impaired by things like fatigue, interruptions and cognitive overload.

### Human factors

‘Human factors’ is the science of the limitations of human performance, and how technology, the work environment and team communication can adapt for this to reduce diagnostic and other types of error. Analysis of serious adverse events in clinical practice shows that human factors and poor team communication play a significant role when things go wrong.

Research shows that many errors are beyond an individual’s conscious control and are precipitated by many factors. The discipline of human factors seeks to understand interactions between:

- people and tasks or technology
- people and their work environment
- people in a team.

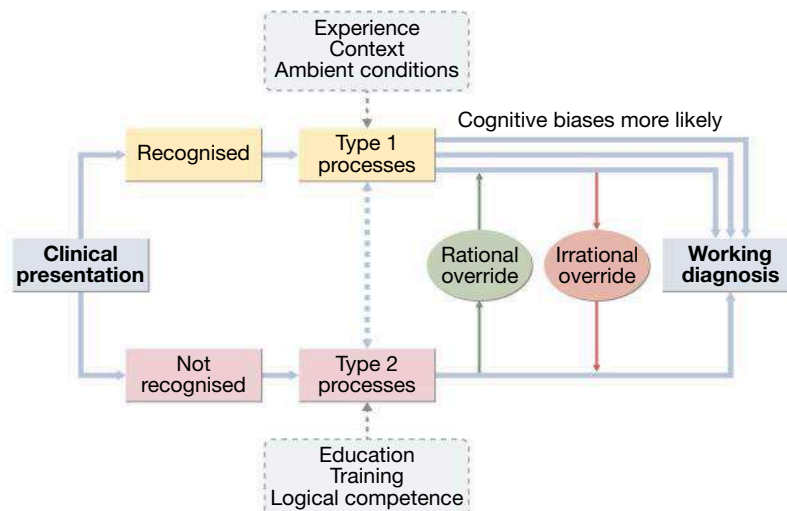

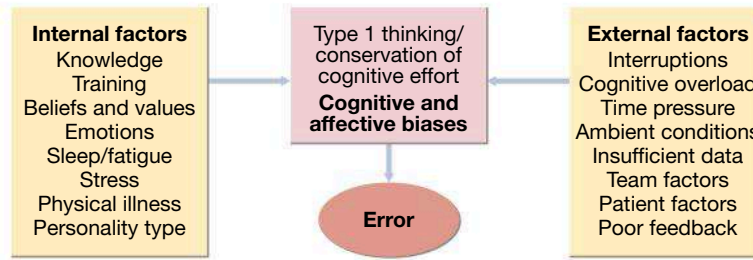

Fig. 1.6 The interplay between type 1 and type 2 thinking in the diagnostic process. Adapted from Croskerry P. A universal model of diagnostic reasoning. *Acad Med* 2009; 84:1022–1028.

<p><b>Anchoring</b> The common human tendency to rely too heavily on the first piece of information offered (the 'anchor') when making decisions</p>	<p><b>Diagnostic momentum</b> Once a diagnostic label has been attached to a patient (by the patient or other health-care professionals), it can gather momentum with each review, leading others to exclude other possibilities in their thinking</p>	<p><b>Premature closure</b> The tendency to close the decision-making process prematurely and accept a diagnosis before it, and other possibilities, have been fully explored</p>
<p><b>Ascertainment bias</b> We sometimes see what we expect to see ('self-fulfilling prophecy'). For example, a frequent self-harmer attends the emergency department with drowsiness; everyone assumes he has taken another overdose and misses a brain injury</p>	<p><b>Framing effect</b> How a case is presented – for example, in handover – can generate bias in the listener. This can be mitigated by always having 'healthy scepticism' about other people's diagnoses</p>	<p><b>Psych-out error</b> Psychiatric patients who present with medical problems are under-assessed, under-examined and under-investigated because problems are presumed to be due to, or exacerbated by, their psychiatric condition</p>
<p><b>Availability bias</b> Things may be at the forefront of your mind because you have seen several cases recently or have been studying that condition in particular. For example, when one of the authors worked in an epilepsy clinic, all blackouts were possible seizures</p>	<p><b>Hindsight bias</b> Knowing the outcome may profoundly influence the perception of past events and decision-making, preventing a realistic appraisal of what actually occurred – a major problem in learning from diagnostic error</p>	<p><b>Search satisficing</b> We may stop searching because we have found something that fits or is convenient, instead of systematically looking for the best alternative, which involves more effort</p>
<p><b>Base rate neglect</b> The tendency to ignore the prevalence of a disease, which then distorts Bayesian reasoning. In some cases, clinicians do this deliberately in order to rule out an unlikely but worst-case scenario</p>	<p><b>Omission bias</b> The tendency towards inaction, rooted in the principle of 'first, do no harm.' Events that occur through natural progression of disease are more acceptable than those that may be attributed directly to the action of the health-care team</p>	<p><b>Triage-cueing</b> Triage ensures patients are sent to the right department. However, this leads to 'geography is destiny'. For example, a diabetic ketoacidosis patient with abdominal pain and vomiting is sent to surgery. The wrong location (surgical ward) stops people thinking about medical causes of abdominal pain and vomiting</p>
<p><b>Commission bias</b> The tendency towards action rather than inaction, on the assumption that good can come only from doing something (rather than 'watching and waiting')</p>	<p><b>Overconfidence bias</b> The tendency to believe we know more than we actually do, placing too much faith in opinion instead of gathered evidence</p>	<p><b>Unpacking principle</b> Failure to 'unpack' all the available information may mean things are missed. For example, if a thorough history is not obtained from either the patient or carers (a common problem in geriatric medicine), diagnostic possibilities may be discounted</p>
<p><b>Confirmation bias</b> The tendency to look for confirming evidence to support a theory rather than looking for disconfirming evidence to refute it, even if the latter is clearly present. Confirmation bias is common when a patient has been seen first by another doctor</p>	<p><b>Posterior probability</b> Our estimate of the likelihood of disease may be unduly influenced by what has gone on before for a particular patient. For example, a patient who has been extensively investigated for headaches presents with a severe headache, and serious causes are discounted</p>	<p><b>Visceral bias</b> The influence of either negative or positive feelings towards patients, which can affect our decision-making</p>

**Fig. 1.7 Common cognitive biases in medicine.** Adapted from Croskerry P. *Achieving quality in clinical decision-making: cognitive strategies and detection of bias.* *Acad Emerg Med* 2002; 9:1184–1204.

An understanding of these interactions makes it easier for health-care professionals, who are committed to 'first, do no harm', to work in the safest way possible. For example, performance is adversely affected by factors such as poorly designed processes and equipment, fatigue and poor communication. So simple, clear processes, good design of equipment and shift patterns, and clear team communication all help to minimise errors.

The areas of the brain required for type 2 processing are most affected by things like fatigue and cognitive overload, and the brain reverts to type 1 processing to conserve cognitive energy. [Figure 1.8](#) illustrates some of the internal and external factors that affect human judgement and decision-making. An awareness of the factors that impact on decision-making can allow clinicians to take steps to mitigate these.

**Fig. 1.8** Factors that affect our judgement and decision-making. (Type 1 thinking = fast, intuitive, subconscious, low effort)

Several studies demonstrate that we focus our attention to filter out distractions. This is advantageous in many situations (for example, when performing a procedure), but in focusing on what we are trying to see we may not notice the unexpected. In a team context, what is obvious to one person may be completely missed by someone else. Safe and effective team communication therefore requires us never to assume, and to verbalise things, even though they may seem ‘obvious’.

## Shared decision-making

Shared decision-making refers to the fact that clinical reasoning does not necessarily take place solely within a clinician’s head. Good decision-making is often shared with patients, relatives and carers, within teams, and by using guidelines, clinical prediction rules and other decision aids. Integral to all of this is the ability to engage in optimal decision-making behaviours: involving the patient and/or carers in the diagnostic and management process, listening to others, following evidence-based guidelines, asking for help when needed, and using clear communication, especially when handing over care.

## Patient-centred evidence-based medicine

‘Patient-centred evidence-based medicine’ refers to the application of best available research evidence while taking individual patient factors into account; these include both clinical and non-clinical factors (e.g. the patient’s social circumstances, values and wishes). For example, a 95-year-old man with dementia and a recent gastrointestinal bleed is admitted with an inferior myocardial infarction. He is clinically well. Should he be treated with dual antiplatelet therapy and low-molecular-weight heparin as recommended in clinical guidelines?

As this chapter has described, clinicians frequently deal with uncertainty/probability. Clinicians need to be able to explain risks and benefits of treatment in an accurate and understandable way. Providing the relevant statistics is seldom sufficient to guide decision-making because a patient’s perception of risk may be influenced by irrational factors as well as individual values.

Research evidence provides statistics but these can be confusing. Terms such as ‘common’ and ‘rare’ are nebulous. Whenever possible, clinicians should quote numerical information using consistent denominators (e.g. ‘90 out of 100 patients who have this operation feel much better, 1 will die during the operation and 2 will suffer a stroke’). Visual aids can be used to present complex statistical information (Fig. 1.9).

How uncertainty is conveyed to patients is important. Many studies demonstrate a correlation between effective clinician–patient communication and improved health outcomes. If patients feel they have been listened to and understand the problem and proposed treatment plan, they are more likely to follow the plan and less likely to re-attend.

## Effective team communication

In increasingly complex health-care systems, patients are looked after by a wide variety of professionals, each of whom has access to important

information required to make clinical decisions. Strict hierarchies are hazardous to patient safety if certain members of the team do not feel able to speak up.

The SBAR system of communication has been recommended by the UK’s Patient Safety First campaign. It is a structured way to communicate about a patient with another health-care professional (e.g. during handover or when making a referral) and increases the amount of relevant information being communicated in a shorter time. It is illustrated in Box 1.7.

## Using clinical prediction rules and other decision aids

A clinical prediction rule is a statistical model of the diagnostic process. When clinical prediction rules are matched against the opinion of experts, the model usually outperforms the experts, because it is applied consistently in each case. However, it is important that clinical prediction rules are used correctly – that is, applied to the patient population that was used to create the rule. Clinical prediction rules force a scientific assessment of the patient’s symptoms, signs and other data to develop a numerical probability of a disease or an outcome. They help clinicians to estimate probability more accurately.

A good example of a clinical prediction rule to estimate pre-test probability is the Wells score in suspected deep vein thrombosis (see Box 9.18). Other commonly used clinical prediction rules predict outcomes and therefore guide the management plan. These include the GRACE score in acute coronary syndromes (see Fig. 16.61) and the CURB-65 score in community-acquired pneumonia (see Fig. 17.32).

## Reducing errors in clinical decision-making

### Deliberate practice

Studies of expertise reveal that extensive experience is necessary to achieve high levels of performance, but extensive experience does not by itself lead to expert levels of achievement. Something else is required, encapsulated in the term ‘deliberate practice’. This involves *effortful* practice, coaching and feedback, and the ability of an individual to plan, assess, reflect and adjust so their performance improves.

### Cognitive debiasing strategies

Knowledge and experience alone, however, do not eliminate errors. There are some simple and established techniques that can be used to avoid cognitive biases and errors in clinical decision-making.

### History and physical examination

Taking a history and performing a physical examination may seem obvious, but these are sometimes carried out inadequately. This is the ‘unpacking principle’: failure to unpack all the available information means things can be missed and lead to error.

**Fig. 1.9** Visual portrayal of benefits and risks. The image refers to an operation that is expected to relieve symptoms in 90% of patients, but cause stroke in 2% and death in 1%. From Edwards A, Elwyn G, Mulley A. Explaining risks: turning numerical data into meaningful pictures. *BMJ* 2002; 324:827–830, reproduced with permission from the BMJ Publishing Group.

1.7 The SBAR system of communicating	
<b>SBAR</b>	<b>Example (a telephone call to the Intensive Care team)</b>
<b>Situation</b>	I am [name] calling from [place] about a patient with a NEWS* of 10.
<b>Background</b>	[Patient's name], 30-year-old woman, no past medical history, was admitted last night with community-acquired pneumonia. Since then her oxygen requirements have been steadily increasing.
<b>Assessment</b>	Her vital signs are: blood pressure 115/60 mmHg, heart rate 120 beats/min, temperature 38°C, respiratory rate 32 breaths/min, oxygen saturations 89% on 15L via reservoir bag mask. An arterial blood gas shows H <sup>+</sup> 50 nmol/L (pH 7.3), PaCO <sub>2</sub> 4.0 kPa (30 mmHg), PaO <sub>2</sub> 7 kPa (52.5 mmHg), standard bicarbonate 14 mmol/L. Chest X-ray shows extensive right lower zone consolidation.
<b>Recommendation</b>	Please can you come and see her as soon as possible? I think she needs admission to Intensive Care.
*NEWS = National Early Warning Score; a patient with normal vital signs scores 0. See Royal College of Physicians. National Early Warning Score (NEWS) 2: Standardising the assessment of acute-illness severity in the NHS. Updated report of a working party. London: RCP; December 2017.	

## Problem representation/list and differential diagnosis

Once all the available data from history, physical examination and (sometimes) initial test results are available, these need to be synthesised into a problem representation or problem list. The process of generating a problem list ensures nothing is missed. The process of generating a differential diagnosis works against anchoring on a particular diagnosis too early, thereby avoiding search satisficing and premature closure (see Fig. 1.6).

## Mnemonics and checklists

These are used frequently in medicine in order to reduce reliance on fallible human memory. ABCDE (airway, breathing, circulation, disability, exposure/examination) is probably the most successful checklist in medicine, used during the assessment and treatment of critically ill patients (ABCDE is sometimes prefixed with 'C' for 'control of any obvious problem'; see p. 191). Checklists ensure that important issues have been considered and completed, especially under conditions of complexity, stress or fatigue.

## Red flags and ROWS ('rule out worst-case scenario')

These are strategies that force doctors to consider serious diseases that can present with common symptoms. Red flags in back pain are listed in Box 26.19. Considering and investigating for possible pulmonary embolism in patients who present with pleuritic chest pain and breathlessness is a common example of ruling out a worst-case scenario, as pulmonary embolism can be fatal if missed. Red flags and ROWS help to avoid cognitive biases such as the 'framing effect' and 'premature closure'.

Newer strategies to avoid cognitive biases and errors in decision-making are emerging. These involve explicit training in clinical reasoning and human factors. In theory, if doctors are aware of the science of human thinking and decision-making, then they are more able to think about their thinking, understand situations in which their decision-making may be affected, and take steps to mitigate this.

## Clinical decision-making: putting it all together

The following is a practical example that brings together many of the concepts outlined in this chapter:

A 25-year-old woman presents with right-sided pleuritic chest pain and breathlessness. She reports that she had an upper respiratory tract infection a week ago and was almost back to normal when the symptoms started. The patient has no past medical history and no family history, and her only medication is the combined oral contraceptive pill. On examination, her vital signs are normal (respiratory rate 19 breaths/min, oxygen saturations 98% on air, blood pressure 115/60 mmHg, heart rate 90 beats/min, temperature 37.5°C) and the physical examination is also normal. You have been asked to assess her for the possibility of a pulmonary embolism.

(More information on pulmonary embolism can be found in Chapter 17.)

## Evidence-based history and examination

Information from the history and physical examination is vital in deciding whether this could be a pulmonary embolism. Pleurisy and breathlessness are common presenting features of this disease but are also common presenting features in other diseases. There is nothing in the history to suggest an alternative diagnosis (e.g. high fever, productive cough, recent chest trauma). The patient's vital signs are normal, as is the physical examination. However, very few individual findings help to distinguish patients with pulmonary embolism from those without it. The presence of wheeze and a high fever modestly decrease the probability of pulmonary embolism. The presence of hypoxaemia is unhelpful (likelihood ratio not significant).

## Deciding pre-test probability

The prevalence of pulmonary embolism (PE) in 25-year-old women is low. We anchor on this prevalence and then adjust for individual patient factors. This patient has no major risk factors for pulmonary embolism. To assist our estimate of pre-test probability, we could use a clinical

prediction rule: in this case, the modified Wells score for pulmonary embolism, which would give a score of 3 (low probability – answering yes only to the criterion ‘PE is the number one diagnosis, an alternative is less likely’).

## Interpreting test results

Imagine the patient went on to have a normal chest X-ray and blood results, apart from a raised D-dimer of 900 (normal <500 ng/mL). A normal chest X-ray is a common finding in pulmonary embolism. Several studies have shown that the D-dimer assay has at least 95% sensitivity in acute pulmonary embolism but it has a low specificity. A very sensitive test will detect most disease but generate abnormal findings in healthy people. On the other hand, a negative result virtually, but not completely, excludes the disease. It is important at this point to realise that a raised D-dimer result does not mean this patient has a pulmonary embolism; it just means that we have not been able to exclude it. Since pulmonary embolism is a potentially fatal condition we need to rule out the worst-case scenario (ROWS), and the next step is therefore to arrange further imaging. What kind of imaging depends on individual patient characteristics and what is available.

## Treatment threshold

The treatment threshold combines factors such as the risks of the test, and the risks versus benefits of treatment. A CT pulmonary angiogram (CTPA) could be requested for this patient, although in some circumstances ventilation–perfusion single-photon emission computed tomography (V/QSPECT, p. 547) may be a more suitable alternative. However, what if the scan cannot be performed until the next day? Because pulmonary embolism is potentially fatal and the risks of treatment in this case are low, the patient should be started on treatment while awaiting the scan.

## Post-test probability

The patient’s scan result is subsequently reported as ‘no pulmonary embolism’. Combined with the low pre-test probability, this scan result reliably excludes pulmonary embolism.

## Cognitive biases

Imagine during this case that the patient had been handed over to you as ‘nothing wrong – probably a pulled muscle’. Cognitive biases (sub-conscious tendencies to respond in a certain way) would come into play, such as the ‘framing effect’, ‘confirmation bias’ and ‘search satisficing’. The normal clinical examination might confirm the diagnosis of musculoskeletal pain in your mind, despite the examination being entirely consistent with pulmonary embolism and despite the lack of history and examination findings (e.g. chest wall tenderness) to support the diagnosis of musculoskeletal chest pain.

## Human factors

Imagine that, after you have seen the patient, a colleague hands you some blood forms and asks you what tests you would like to request on ‘this lady’. You request blood tests including a D-dimer on the wrong patient. Luckily, this error is intercepted.

## Shared decision-making

The diagnosis of pulmonary embolism can be difficult. Clinical prediction rules (e.g. modified Wells score), guidelines (e.g. from the UK’s National

Institute for Health and Care Excellence, or NICE) and decision aids (e.g. simplified pulmonary embolism severity index, or PESI) are frequently used in combination with the doctor’s opinion, derived from information gathered in the history and physical examination.

The patient is treated according to evidence-based guidelines that apply to her particular situation. Tests alone do not make a diagnosis and at the end of this process the patient is told that the combination of history, examination and test results mean she is extremely unlikely to have a pulmonary embolism. Viral pleurisy is offered as an alternative diagnosis and she is reassured that her symptoms are expected to settle over the coming days with analgesia. She is advised to re-present to hospital if her symptoms get worse.

## Answers to problems

### Harvard problem (p. 5)

Almost half of doctors surveyed said 95%, but they neglected to take prevalence into account. If 1000 people are tested, there will be 51 positive results: 50 false positives and 1 true positive (assuming 100% sensitivity). The chance that a person found to have a positive result actually has the disease is therefore only 1/51 or ~2%.

### Bat and ball problem (p. 6)

This puzzle is from the book *Thinking, Fast and Slow*, by Nobel laureate Daniel Kahneman (see ‘Further information’). He writes, ‘A number came to your mind. The number, of course, is 10p. The distinctive mark of this easy puzzle is that it evokes an answer that is intuitive, appealing – and wrong. Do the math, and you will see.’ The correct answer is 5p.

## Multiple Choice Questions

- 1.1. Which of the following best describes what is meant by the term 'shared decision-making'?
- A. Allowing the patient to make decisions about his or her care
  - B. Asking for help when needed
  - C. Making decisions with the wider clinical team
  - D. Patient-centred evidence-based medicine
  - E. Sharing decision-making with the patient, relatives, clinical team, guidelines and decision aids

Answer: E.

Shared decision-making refers to the fact that clinical reasoning does not necessarily take place solely within a clinician's head. Good decision-making is often shared with patients, relatives and carers, within teams, and by using guidelines, clinical prediction rules and other decision aids. Integral to all of this is the ability to engage in optimal decision-making behaviours: involving the patient and/or carers in the diagnostic and management process, listening to others, following evidence-based guidelines, asking for help when needed, and using clear communication, especially when handing over care.

- 1.2. Which of the following best describes what is meant by the term 'metacognitive knowledge'?
- A. An awareness of and an ability to think about one's own thinking
  - B. An understanding of how things fit together
  - C. An understanding of how to do something, what techniques to use
  - D. The tendency to engage in deliberate practice
  - E. The tendency to look for evidence, weigh things up and be aware of context

Answer: A.

Metacognition literally means 'thinking about thinking', 'knowing about knowing', and being 'aware of one's awareness'. Metacognitive knowledge is about being aware of one's own cognitive processes and is a key ingredient for successful learning and the development of expertise.

- 1.3. When using a clinical prediction rule for a specific condition, which of the following is true?
- A. The tool can be applied to any patient with the condition
  - B. The tool can determine the clinical probability that a patient has a disease
  - C. The tool is not necessarily based on evidence
  - D. The tool uses the receiver operating characteristic curve to statistically model the diagnostic process
  - E. Use of the tool removes the need for clinical decision-making on the part of the clinician

Answer: B.

A clinical prediction rule is a statistical model of the diagnostic process. When clinical prediction rules are matched against the opinion of

experts, the model usually outperforms the experts, because it is applied consistently in each case. However, it is important that clinical prediction rules are used correctly – that is, applied to the patient population that was used to create the rule. Clinical prediction rules force a scientific assessment of the patient's symptoms, signs and other data to develop a numerical probability of a disease or an outcome. They help clinicians to estimate probability more accurately. A good example of a clinical prediction rule to estimate pre-test probability is the Wells score in suspected deep vein thrombosis.

- 1.4. Regarding normal values, which of the following statements is true?

- A. A normal result means that disease is not present
- B. A normal result specific to a particular disease is not found in a person with the disease
- C. Normal values do not vary significantly within the same person
- D. Normal values follow a Poisson distribution
- E. One in 20 healthy people will have values that lie outside the reference range

Answer: E.

Most tests provide quantitative results on a continuous numerical scale. In order to classify quantitative results as normal or abnormal, it is necessary to define a cut-off point. Many quantitative measurements in populations have a Gaussian or 'normal' distribution. By convention, the normal (reference) range is defined as those values that encompass 95% of the population, or 2 standard deviations above and below the mean. This means that 2.5% of the normal population will have values above, and 2.5% will have values below the normal range. In some diseases there is no overlap between results from the abnormal and normal population. However, in many diseases there is overlap. So a healthy person can have an 'abnormal' result, and a person with disease can have a 'normal' result. Normal values also vary from day to day in the same person in the absence of a real change because of biological variation and laboratory variation. The extent to which a blood test is allowed to vary before it has truly changed is called the 'critical difference'.

- 1.5. An 80-year-old man presented with a fall on a background of a 2-week history of his legs 'giving way' and a history of increasing low back pain. In this scenario, which of the following strategies to reduce errors in clinical reasoning would be most appropriate?
- A. An assessment of his mobility
  - B. An X-ray of the lumbar spine
  - C. Generating a problem representation
  - D. Use of a clinical prediction rule
  - E. Using red flags and 'ROWS' (rule out worst-case scenario)

Answer: E.

Various strategies can be used to reduce errors in clinical reasoning including: taking a proper history and performing a thorough physical examination, generating a problem representation, and using mnemonics and checklists. Using red flags and ROWS (rule out worst-case scenario) forces clinicians to think about serious diseases that can present with common symptoms. In this example, it forces clinicians to consider the possibility of cord compression. Red flags and ROWS helps to avoid cognitive biases such as the 'framing effect' and 'premature closure'.

Prescribing medicines is the major tool used by doctors to restore or preserve the health of patients. Medicines contain drugs (the specific chemical substances with pharmacological effects), either alone or in combination with additional drugs, in a formulation mixed with other ingredients. The beneficial effects of medicines must be weighed against their cost and potential adverse drug reactions and interactions. The latter two factors are sometimes caused by injudicious prescribing decisions and by prescribing errors. The modern prescriber must meet the challenges posed by the increasing number of drugs and formulations available, of indications for prescribing them and the greater complexity of treatment regimens followed by individual patients ('polypharmacy', a particular challenge in the ageing population). The purpose of this chapter is to elaborate on the principles and practice that underpin good prescribing (Box 2.1).

## 2.1 Steps in good prescribing

- Make a diagnosis
- Consider factors that might influence the patient's response to therapy (age, concomitant drug therapy, renal and liver function etc.)
- Establish the therapeutic goal\*
- Choose the therapeutic approach\*
- Choose the drug and its formulation (the 'medicine')
- Choose the dose, route and frequency
- Choose the duration of therapy
- Write an unambiguous prescription (or 'medication order')
- Inform the patient about the treatment and its likely effects
- Monitor treatment effects, both beneficial and harmful
- Review/alter the prescription

\*These steps in particular take the patient's views into consideration to establish a therapeutic partnership that aims to achieve 'concordance' based on shared decision-making.

## Principles of clinical pharmacology

Prescribers need to understand what the drug does to the body (pharmacodynamics) and what the body does to the drug (pharmacokinetics) (Fig. 2.1). Although this chapter is focused on the most common drugs, which are synthetic small molecules, the same principles apply to the increasingly numerous 'biologic' therapies (sometimes abbreviated to 'biologics') now in use, which include peptides, proteins, enzymes and monoclonal antibodies.

### Pharmacodynamics

#### Drug targets and mechanisms of action

Modern drugs are usually discovered by screening compounds for activity either to stimulate or to block the function of a specific molecular target, which is predicted to have a beneficial effect in a particular disease (Box 2.2). Other drugs have useful but less selective chemical properties, such as chelators (e.g. for treatment of iron or copper overload), osmotic agents (used as diuretics in cerebral oedema) or general anaesthetics (that alter the biophysical properties of lipid membranes). The following characteristics of the interaction of drugs with receptors illustrate some of the important determinants of the effects of drugs:

- *Affinity* describes the propensity for a drug to bind to a receptor and is related to the 'molecular fit' and the strength of the chemical bond. Some drug–receptor interactions are *irreversible*, either because the affinity is so strong or because the drug modifies the structure of its molecular target.
- *Selectivity* describes the propensity for a drug to bind to one target rather than another. Selectivity is a relative term, not to be confused with absolute specificity. It is common for drugs targeted

Fig. 2.1 Pharmacokinetics and pharmacodynamics.

at a particular subtype of receptor to exhibit some effect at other subtypes. For example,  $\beta$ -adrenoceptors can be subtyped on the basis of their responsiveness to the endogenous agonist noradrenaline (norepinephrine): the concentration of noradrenaline required to cause bronchodilatation (via  $\beta_2$ -adrenoceptors) is 10 times higher than that required to cause tachycardia (via  $\beta_1$ -adrenoceptors). 'Cardioselective'  $\beta$ -adrenoceptor antagonists ( $\beta$ -blockers) have anti-anginal effects on the heart ( $\beta_1$ ), but may still cause bronchospasm in the lung ( $\beta_2$ ) and are contraindicated for asthmatic patients.

- *Agonists* bind to a receptor to produce a conformational change that is coupled to a biological response. As agonist concentration increases, so does the proportion of receptors occupied, and hence the biological effect. *Partial agonists* activate the receptor, but cannot produce a maximal signalling effect equivalent to that of a full agonist even when all available receptors are occupied.
- *Antagonists* bind to a receptor, but do not produce the conformational change that initiates an intracellular signal. A *competitive antagonist* competes with endogenous agonist ligands to occupy receptor-binding sites, with the resulting antagonism depending on the relative affinities and concentrations of the antagonist drug and endogenous agonist. *Non-competitive antagonists* inhibit the effect of an agonist by mechanisms other than direct competition for receptor binding with the agonist (e.g. by affecting post-receptor signalling).

### Dose–response relationships

Plotting the logarithm of drug dose against drug response typically produces a sigmoidal dose–response curve (Fig. 2.2). Progressive increases in drug dose (which, for most drugs, is proportional to the plasma drug concentration) produce increasing response, but only within a relatively narrow range of dose; further increases in dose beyond this range produce little extra effect. The following characteristics of the drug response are useful in comparing different drugs:

- *Efficacy* describes the extent to which a drug can produce a target-specific response when all available receptors or binding sites are occupied (i.e.  $E_{max}$  on the dose–response curve). A full agonist can produce the maximum response of which the receptor is capable, while a partial agonist at the same receptor will have lower efficacy. *Therapeutic efficacy* describes the effect of the drug on a desired biological endpoint and can be used to compare drugs that act via different pharmacological mechanisms (e.g. loop diuretics

## 2.2 Examples of target molecules for drugs

Drug target	Description	Examples
<b>Receptors</b>		
Channel-linked receptors	Ligand binding controls a linked ion channel, known as 'ligand-gated' (in contrast to 'voltage-gated' channels that respond to changes in membrane potential)	Nicotinic acetylcholine receptor GABA receptor Sulphonylurea receptor
G-protein-coupled receptors (GPCRs)	Ligand binding affects one of a family of 'G-proteins' that mediate signal transduction either by activating intracellular enzymes (such as adenylate or guanylate cyclase, producing cyclic AMP or GMP, respectively) or by controlling ion channels	Muscarinic acetylcholine receptor $\beta$ -adrenoceptors Dopamine receptors 5-Hydroxytryptamine (5-HT, serotonin) receptors Opioid receptors
Kinase-linked receptors	Ligand binding activates an intracellular protein kinase that triggers a cascade of phosphorylation reactions	Insulin receptor Cytokine receptors
Transcription factor receptors	Intracellular and also known as 'nuclear receptors'; ligand binding promotes or inhibits gene transcription and hence synthesis of new proteins	Steroid receptors Thyroid hormone receptors Vitamin D receptors Retinoid receptors PPAR $\gamma$ and $\alpha$ receptors
<b>Other targets</b>		
Voltage-gated ion channels	Mediate electrical signalling in excitable tissues (muscle and nervous system)	Na <sup>+</sup> channels Ca <sup>2+</sup> channels
Enzymes	Catalyse biochemical reactions. Drugs interfere with binding of substrate to the active site or of co-factors	Cyclo-oxygenase ACE Xanthine oxidase
Transporter proteins	Carry ions or molecules across cell membranes	5-HT re-uptake transporter Na <sup>+</sup> /K <sup>+</sup> ATPase
Cytokines and other signalling molecules	Small proteins that are important in cell signalling (autocrine, paracrine and endocrine), especially affecting the immune response	Tumour necrosis factors Interleukins
Cell surface antigens	Block the recognition of cell surface molecules that modulate cellular responses	Cluster of differentiation molecules (e.g. CD20, CD80)

(ACE = angiotensin-converting enzyme; AMP = adenosine monophosphate; ATPase = adenosine triphosphatase; GABA =  $\gamma$ -aminobutyric acid; GMP = guanosine monophosphate; PPAR = peroxisome proliferator-activated receptor)

**Fig. 2.2 Dose-response curve.** The green curve represents the beneficial effect of the drug. The maximum response on the curve is the  $E_{max}$  and the dose (or concentration) producing half this value ( $E_{max}/2$ ) is the  $ED_{50}$  (or  $EC_{50}$ ). The red curve illustrates the dose-response relationship for the most important adverse effect of this drug. This occurs at much higher doses; the ratio between the  $ED_{50}$  for the adverse effect and that for the beneficial effect is the 'therapeutic index', which indicates how much margin there is for prescribers when choosing a dose that will provide beneficial effects without also causing this adverse effect. Adverse effects that occur at doses above the therapeutic range are normally called 'toxic effects', while those occurring within the therapeutic range are 'side-effects' and those below it are 'hyper-susceptibility effects'.

induce a greater diuresis than thiazide diuretics and so have greater therapeutic efficacy).

- *Potency* describes the amount of drug required for a given response. More potent drugs produce biological effects at lower doses, so they have a lower  $ED_{50}$ . A less potent drug can still have an equivalent or greater efficacy if it is given in higher doses.

The dose–response relationship for a specific drug varies between patients because of variations in the many determinants of pharmacokinetics and pharmacodynamics. In clinical practice, the prescriber is unable to construct a dose–response curve for each individual patient. Therefore, most drugs are licensed for use within a recommended range of doses that is expected to reach close to the top of the dose–response curve for most patients. However, it is sometimes possible to achieve the desired therapeutic efficacy at doses towards the lower end of, or even below, the recommended range.

### Therapeutic index

The adverse effects of drugs are often dose-related in a similar way to the beneficial effects, although the dose–response curve for these adverse effects is normally shifted to the right (see Fig. 2.2). The ratio of the  $ED_{50}$  for therapeutic efficacy and for a major adverse effect is known as the ‘therapeutic index’. In reality, drugs have multiple potential adverse effects, but the concept of therapeutic index is usually based on adverse effects that might require dose reduction or discontinuation. For most drugs, the therapeutic index is greater than 100, but there are some notable exceptions with therapeutic indices of less than 10 (e.g. digoxin, warfarin, insulin, phenytoin, opioids). The doses of such drugs have to be titrated carefully for individual patients to maximise benefits, but avoid adverse effects.

### Desensitisation and withdrawal effects

Desensitisation refers to the common situation in which the biological response to a drug diminishes when it is given continuously or repeatedly. It may be possible to restore the response by increasing the dose of the drug but, in some cases, the tissues may become completely refractory to its effect.

- *Tachyphylaxis* describes desensitisation that occurs very rapidly, sometimes with the initial dose. This rapid loss of response implies depletion of chemicals that may be necessary for the

pharmacological actions of the drug (e.g. a stored neurotransmitter released from a nerve terminal) or receptor phosphorylation.

- *Tolerance* describes a more gradual loss of response to a drug that occurs over days or weeks. This slower change implies changes in receptor numbers or the development of counter-regulatory physiological changes that offset the actions of the drug (e.g. accumulation of salt and water in response to vasodilator therapy).
- *Drug resistance* is a term normally reserved for describing the loss of effectiveness of an antimicrobial (p. 113) or cancer chemotherapy drug.
- In addition to these pharmacodynamic causes of desensitisation, reduced response may be the consequence of lower plasma and tissue drug concentrations as a result of altered *pharmacokinetics* (see below).

When drugs induce chemical, hormonal and physiological changes that offset their actions, discontinuation may allow these changes to cause ‘rebound’ withdrawal effects (Box 2.3).

## Pharmacokinetics

Understanding ‘what the body does to the drug’ (Fig. 2.3) is extremely important for prescribers because this forms the basis on which the optimal route of administration and dose regimen are chosen and explains the majority of inter-individual variation in the response to drug therapy.

### Drug absorption and routes of administration

Absorption is the process by which drug molecules gain access to the blood stream. The rate and extent of drug absorption depend on the route of administration (see Fig. 2.3).

#### Enteral administration

These routes involve administration via the gastrointestinal tract:

- *Oral*. This is the most common route of administration because it is simple, convenient and readily used by patients to self-administer their medicines. Absorption after an oral dose is a complex process that depends on the drug being swallowed, surviving exposure to gastric acid, avoiding unacceptable food binding, being absorbed across the small bowel mucosa into the portal venous system, and surviving metabolism by gut wall or liver enzymes

i 2.3 Examples of drugs associated with withdrawal effects			
Drug	Symptoms	Signs	Treatment
Alcohol	Anxiety, panic, paranoid delusions, visual and auditory hallucinations	Agitation, restlessness, delirium, tremor, tachycardia, ataxia, disorientation, seizures	Treat immediate withdrawal syndrome with benzodiazepines
Barbiturates, benzodiazepines	Similar to alcohol	Similar to alcohol	Transfer to long-acting benzodiazepine then gradually reduce dosage
Glucocorticoids	Weakness, fatigue, decreased appetite, weight loss, nausea, vomiting, diarrhoea, abdominal pain	Hypotension, hypoglycaemia	Prolonged therapy suppresses the hypothalamic–pituitary–adrenal axis and causes adrenal insufficiency requiring glucocorticoid replacement. Withdrawal should be gradual after prolonged therapy (p. 684)
Opioids	Rhinorrhoea, sneezing, yawning, lacrimation, abdominal and leg cramping, nausea, vomiting, diarrhoea	Dilated pupils	Transfer addicts to long-acting agonist methadone
Selective serotonin re-uptake inhibitors (SSRIs)	Dizziness, sweating, nausea, insomnia, tremor, delirium, nightmares	Tremor	Reduce SSRIs slowly to avoid withdrawal effects

('first-pass metabolism'). As a consequence, absorption is frequently incomplete following oral administration. The term 'bioavailability' describes the proportion of the dose that reaches the systemic circulation intact.

- *Buccal and sublingual (SL)*. These routes have the advantage of enabling rapid absorption into the systemic circulation without the uncertainties associated with oral administration (e.g. organic nitrates for angina pectoris, triptans for migraine, opioid analgesics).
- *Rectal (PR)*. The rectal mucosa is occasionally used as a site of drug administration when the oral route is compromised because of nausea and vomiting or unconsciousness (e.g. diazepam in status epilepticus).

### Parenteral administration

These routes avoid absorption via the gastrointestinal tract and first-pass metabolism in the liver:

- *Intravenous (IV)*. The IV route enables all of a dose to enter the systemic circulation reliably, without any concerns about absorption or first-pass metabolism (i.e. the dose is 100% bioavailable), and rapidly achieve a high plasma concentration. It is ideal for very ill patients when a rapid, certain effect is critical to outcome (e.g. benzylpenicillin for meningococcal meningitis).
- *Intramuscular (IM)*. IM administration is easier to achieve than the IV route (e.g. adrenaline (epinephrine) for acute anaphylaxis), but absorption is less predictable and depends on muscle blood flow.
- *Subcutaneous (SC)*. The SC route is ideal for drugs that have to be administered parenterally because of low oral bioavailability, are absorbed well from subcutaneous fat and can ideally be injected by patients themselves (e.g. insulin, heparin).
- *Transdermal*. A transdermal patch can enable a drug to be absorbed through the skin and into the circulation (e.g. oestrogens, nicotine, nitrates).
- *Nasal*. The nasal mucosa provides another potential route for absorption of some drugs with systemic action (e.g. sumatriptan, calcitonin, naloxone, testosterone, desmopressin).

### Other routes of administration

- *Topical* application of a drug involves direct administration to the site of action (e.g. skin, eye, ear). This has the advantage of achieving sufficient concentration at this site while minimising systemic exposure and the risk of adverse effects elsewhere.
- *Inhaled (INH)* administration allows drugs to be delivered directly to a target in the respiratory tree, usually the small airways (e.g. salbutamol, beclometasone). However, a significant proportion of the inhaled dose may be absorbed from the lung or is swallowed and can reach the systemic circulation. The most common mode of delivery is the metered-dose inhaler, but its success depends

on some degree of manual dexterity and timing (see Fig. 17.23).

Patients who find these difficult may use a 'spacer' device to improve drug delivery. A special mode of inhaled delivery is via a nebulised solution created by using pressurised oxygen or air to break up solutions and suspensions into small aerosol droplets that can be directly inhaled from the mouthpiece of the device.

## Drug distribution

Distribution is the process by which drug molecules transfer between the circulating blood, interstitial space and intracellular fluid. This is influenced by the drug's molecular size and lipid solubility, the extent to which it binds to proteins in plasma, its susceptibility to drug transporters expressed on cell surfaces and its binding to its molecular target and to other cellular proteins (which can be irreversible). Most drugs diffuse passively across capillary walls down a concentration gradient into the interstitial fluid until the concentration of free drug molecules in the interstitial fluid is equal to that in the plasma. As drug molecules in the blood are removed by metabolism or excretion, the plasma concentration falls and drug molecules diffuse back from the tissue compartment into the blood until eventually all are eliminated. Note that this reverse movement of drug away from the tissues will be prevented if further drug doses are administered and absorbed into the plasma.

### Volume of distribution

The apparent volume of distribution ( $V_d$ ) is the volume into which a drug appears to have distributed following intravenous injection. It is calculated from the equation

$$V_d = D/C_0$$

where  $D$  is the amount of drug given and  $C_0$  is the initial plasma concentration (Fig. 2.4A). Drugs that are highly bound to plasma proteins may have a  $V_d$  below 10L (e.g. warfarin, aspirin), while those that diffuse into the interstitial fluid but do not enter cells because they have low lipid solubility may have a  $V_d$  between 10 and 30L (e.g. gentamicin, amoxicillin). It is an 'apparent' volume because those drugs that are lipid-soluble and highly tissue-bound may have a  $V_d$  of greater than 100L (e.g. digoxin, amitriptyline). Drugs with a larger  $V_d$  have longer half-lives (see below), take longer to reach steady state on repeated administration and are eliminated more slowly from the body following discontinuation.

## Drug elimination

### Drug metabolism

Metabolism is the process by which drugs are chemically altered from a lipid-soluble form suitable for absorption and distribution to a more water-soluble form that is necessary for excretion. Some drugs, known as 'prodrugs', are inactive in the form in which they are administered, but are converted to an active metabolite in vivo.

**Fig. 2.3 Pharmacokinetics summary.** Most drugs are taken orally, are absorbed from the intestinal lumen and enter the portal venous system to be conveyed to the liver, where they may be subject to first-pass metabolism and/or excretion in bile. Active drugs then enter the systemic circulation, from which they may diffuse (or sometimes be actively transported) in and out of the interstitial and intracellular fluid compartments. Drug that remains in circulating plasma is subject to liver metabolism and renal excretion. Drugs excreted in bile may be reabsorbed, creating an enterohepatic circulation. First-pass metabolism in the liver is avoided if drugs are administered via the buccal or rectal mucosa, or parenterally (e.g. by intravenous injection).

**Fig. 2.4 Drug concentrations in plasma following single and multiple drug dosing.** **A** In this example of first-order kinetics following a single intravenous dose, the time period required for the plasma drug concentration to halve (half-life,  $t_{1/2}$ ) remains constant throughout the elimination process. **B** After multiple dosing, the plasma drug concentration rises if each dose is administered before the previous dose has been entirely cleared. In this example, the drug's half-life is 30 hours, so that with daily dosing the peak, average and trough concentrations steadily increase as drug accumulates in the body (black line). Steady state is reached after approximately 5 half-lives, when the rate of elimination (the product of concentration and clearance) is equal to the rate of drug absorption (the product of rate of administration and bioavailability). The long half-life in this example means that it takes 6 days for steady state to be achieved and, for most of the first 3 days of treatment, plasma drug concentrations are below the therapeutic range. This problem can be overcome if a larger loading dose (red line) is used to achieve steady-state drug concentrations more rapidly.

Phase I metabolism involves oxidation, reduction or hydrolysis to make drug molecules suitable for phase II reactions or for excretion. Oxidation is by far the most common form of phase I reaction and chiefly involves members of the cytochrome P450 family of membrane-bound enzymes in the endoplasmic reticulum of hepatocytes.

Phase II metabolism involves combining phase I metabolites with an endogenous substrate to form an inactive conjugate that is much more water-soluble. Reactions include glucuronidation, sulphation, acetylation, methylation and conjugation with glutathione. This is necessary to enable renal excretion, because lipid-soluble metabolites will simply diffuse back into the body after glomerular filtration (p. 617).

### Drug excretion

Excretion is the process by which drugs and their metabolites are removed from the body.

Renal excretion is the usual route of elimination for drugs or their metabolites that are of low molecular weight and sufficiently water-soluble to avoid reabsorption from the renal tubule. Drugs bound to plasma proteins are not filtered by the glomeruli. The pH of the urine is more acidic than that of plasma, so that weakly acidic drugs (e.g. salicylates) become un-ionised and tend to be reabsorbed. Alkalinisation of the urine can hasten excretion (e.g. after a salicylate overdose; p. 225). For some drugs, active secretion into the proximal tubule lumen, rather than glomerular filtration, is the predominant mechanism of excretion (e.g. methotrexate, penicillins).

Faecal excretion is the predominant route of elimination for drugs with high molecular weight, including those that are excreted in the bile after conjugation with glucuronide in the liver and any drugs that are not absorbed after enteral administration. Molecules of drug or metabolite that are excreted in the bile enter the small intestine where they may, if they are sufficiently lipid-soluble, be reabsorbed through the gut wall and return to the liver via the portal vein (see Fig. 2.3). This recycling between the liver, bile, gut and portal vein is known as 'enterohepatic circulation' and can significantly prolong the residence of drugs in the body (e.g. digoxin, morphine, levothyroxine).

### Elimination kinetics

The net removal of drug from the circulation results from a combination of drug metabolism and excretion and is usually described as 'clearance', i.e. the volume of plasma that is completely cleared of drug per unit time.

For most drugs, elimination is a high-capacity process that does not become saturated, even at high dosage. The rate of elimination is, therefore, directly proportional to the drug concentration because of the 'law of mass action', whereby higher drug concentrations will drive faster metabolic reactions and support higher renal filtration rates. This results in 'first-order' kinetics, when a constant fraction of the drug remaining in the circulation is eliminated in a given time and the decline in concentration over time is exponential (see Fig. 2.4A). This elimination can be described by the drug's half-life ( $t_{1/2}$ ), i.e. the time taken for the plasma drug concentration to halve, which remains constant throughout the period of drug elimination. The significance of this phenomenon for prescribers is that the effect of increasing doses on plasma concentration is predictable – a doubled dose leads to a doubled concentration at all time points.

For a few drugs in common use (e.g. phenytoin, alcohol), elimination capacity is exceeded (saturated) within the usual dose range. This is called 'zero-order' kinetics. Its significance for prescribers is that, if the rate of administration exceeds the maximum rate of elimination, the drug will accumulate progressively, leading to serious toxicity.

### Repeated dose regimens

The goal of therapy is usually to maintain drug concentrations within the therapeutic range (see Fig. 2.2) over several days (e.g. antibiotics) or even for months or years (e.g. antihypertensives, lipid-lowering drugs, thyroid hormone replacement therapy). This goal is rarely achieved with single doses, so prescribers have to plan a regimen of repeated doses. This involves choosing the size of each individual dose and the frequency of dose administration.

As illustrated in Figure 2.4B, the time taken to reach drug concentrations within the therapeutic range depends on the half-life of the drug. Typically, with doses administered regularly, it takes approximately 5 half-lives to reach a 'steady state' in which the rate of drug elimination is equal to the rate of drug administration. This applies when starting new drugs and when adjusting doses of current drugs. With appropriate dose selection, steady-state drug concentrations will be maintained within the therapeutic range. This is important for prescribers because it means that the effects of a new prescription, or dose titration, for a drug with a long half-life (e.g. digoxin – 36 hours) may not be known for a few days. In contrast, drugs with a very short half-life (e.g. dobutamine – 2 minutes) have to be given continuously by infusion, but reach a new steady state within minutes.

For drugs with a long half-life, if it is unacceptable to wait for 5 half-lives until concentrations within the therapeutic range are achieved, then an initial 'loading dose' can be given that is much larger than the maintenance dose and equivalent to the amount of drug required in the body at steady state. This achieves a peak plasma concentration close to the plateau concentration, which can then be maintained by successive maintenance doses.

'Steady state' actually involves fluctuations in drug concentrations, with peaks just after administration followed by troughs just prior to the next administration. The manufacturers of medicines recommend dosing regimens that predict that, for most patients, these oscillations result in troughs within the therapeutic range and peaks that are not high enough to cause adverse effects. The optimal dose interval is a compromise between convenience for the patient and a constant level of drug exposure. More frequent administration (e.g. 25 mg 4 times daily) achieves a smoother plasma concentration profile than 100 mg once daily, but is much more difficult for patients to sustain. A solution to this need for compromise in dosing frequency for drugs with half-lives of less than 24 hours is the use of 'modified-release' (m/r) formulations. These allow drugs to be absorbed more slowly from the gastrointestinal tract and reduce the oscillation in plasma drug concentration profile, which is especially important for drugs with a low therapeutic index (e.g. levodopa).

### Inter-individual variation in drug responses

Prescribers have numerous sources of guidance about how to use drugs appropriately (e.g. dose, route, frequency, duration) for many conditions. However, this advice is based on average dose-response data derived from observations in many individuals. When applying this information to an individual patient, prescribers must take account of inter-individual variability in response. Some of this variability is predictable and good prescribers are able to anticipate it and adjust their prescriptions accordingly to maximise the chances of benefit and minimise harm. Inter-individual variation in responses also mandates that effects of treatment should be monitored (p. 35).

Some inter-individual variation in drug response is accounted for by differences in pharmacodynamics. For example, the beneficial natriuresis produced by the loop diuretic furosemide is often significantly reduced at a given dose in patients with renal impairment, while delirium caused by opioid analgesics is more likely in the elderly. However, it is differences in pharmacokinetics that more commonly account for different drug responses. Examples of factors influencing the absorption, metabolism and excretion of drugs are shown in Box 2.4.

It is hoped that a significant proportion of the inter-individual variation in drug responses can be explained by studying genetic differences in single genes ('pharmacogenetics'; Box 2.5) or the effects of multiple gene variants ('pharmacogenomics'). The aim is to identify those patients most likely to benefit from specific treatments and those most susceptible to adverse effects. In this way, it may be possible to select drugs and dose regimens for individual patients to maximise the benefit-to-hazard ratio ('personalised medicine').

## Adverse outcomes of drug therapy

The decision to prescribe a drug always involves a judgement of the balance between therapeutic benefits and risk of an adverse outcome. Both prescribers and patients tend to be more focused on the former, but a truly informed decision requires consideration of both.

### Adverse drug reactions

Some important definitions for the adverse effects of drugs are:

- *Adverse event*. A harmful event that occurs while a patient is taking a drug, irrespective of whether the drug is suspected of being the cause.
- *Adverse drug reaction (ADR)*. An unwanted or harmful reaction that is experienced following the administration of a drug or combination of drugs under normal conditions of use and is suspected to be related to the drug. An ADR will usually require the drug to be discontinued or the dose reduced.
- *Side-effect*. Any effect caused by a drug other than the intended therapeutic effect, whether beneficial, neutral or harmful. The term 'side-effect' is often used interchangeably with 'ADR', although the former usually implies an ADR that occurs during exposure to normal therapeutic drug concentrations (e.g. vasodilator-induced ankle oedema).
- *Hypersensitivity reaction*. An ADR that occurs as a result of an immunological reaction and often after exposure to subtherapeutic drug concentrations. These include: (1) acute anaphylaxis (p. 183) – the result of an interaction between drug antigens and immunoglobulin E (IgE) on mast cells and basophils, resulting in a release of vasoactive biomolecules (e.g. penicillin, suxamethonium); this is also known as a type I hypersensitivity reaction. (2) 'Anaphylactoid'

### 2.4 Patient-specific factors that influence pharmacokinetics

#### Age

- Drug metabolism is low in the fetus and newborn, may be enhanced in young children, and becomes less effective with age
- Drug excretion falls with the age-related decline in renal function

#### Sex

- Women have a greater proportion of body fat than men, increasing the volume of distribution and half-life of lipid-soluble drugs

#### Body weight

- Obesity increases volume of distribution and half-life of lipid-soluble drugs
- Patients with higher lean body mass have larger body compartments into which drugs are distributed and may require higher doses

#### Liver function

- Metabolism of most drugs depends on several cytochrome P450 enzymes that are impaired in patients with advanced liver disease
- Hypoalbuminaemia influences the distribution of drugs that are highly protein-bound

#### Kidney function

- Renal disease and the decline in renal function with ageing may lead to drug accumulation

#### Gastrointestinal function

- Small intestinal absorption of oral drugs may be delayed by reduced gastric motility
- Absorptive capacity of the intestinal mucosa may be reduced in disease (e.g. Crohn's or coeliac disease) or after surgical resection

#### Food

- Food in the stomach delays gastric emptying and reduces the rate (but not usually the extent) of drug absorption
- Some food constituents bind to certain drugs and prevent their absorption

#### Smoking

- Tar in tobacco smoke stimulates the oxidation of certain drugs

#### Alcohol

- Regular alcohol consumption stimulates liver enzyme synthesis, while binge drinking may temporarily inhibit drug metabolism

#### Drugs

- Drug-drug interactions cause marked variation in pharmacokinetics (see Box 2.12)

2.5 Examples of pharmacogenetic variations that influence drug response		
Genetic variant	Drug affected	Clinical outcome
<b>Pharmacokinetic</b>		
Aldehyde dehydrogenase-2 deficiency	Ethanol	Elevated blood acetaldehyde causes facial flushing and increased heart rate in ~50% of Japanese, Chinese and other Asian populations
Acetylation	Isoniazid, hydralazine, procainamide	Increased responses in slow acetylators, up to 50% of some populations
Oxidation (CYP2D6)	Nortriptyline Codeine	Increased risk of toxicity in poor metabolisers Reduced responses with slower conversion of codeine to more active morphine in poor metabolisers, 10% of European populations Increased risk of toxicity in ultra-fast metabolisers, 3% of Europeans but 25% of North Africans
Oxidation (CYP2C9)	Warfarin	Polymorphisms known to influence dosages
Oxidation (CYP2C19)	Clopidogrel Proguanil	Reduced enzymatic activation results in reduced antiplatelet effect Reduced efficacy with slower conversion to active cycloguanil in poor metabolisers
Sulphoxidation	Penicillamine	Increased risk of toxicity in poor metabolisers
Pseudocholinesterase deficiency	Suxamethonium (succinylcholine)	Decreased drug inactivation leads to prolonged paralysis and sometimes persistent apnoea requiring mechanical ventilation until the drug can be eliminated by alternate pathways; occurs in 1 in 1500 people
<b>Pharmacodynamic</b>		
Glucose-6-phosphate dehydrogenase (G6PD) deficiency	Oxidant drugs, including antimalarials (e.g. chloroquine, primaquine)	Risk of haemolysis in G6PD deficiency
Acute intermittent porphyria	Enzyme-inducing drugs	Increased risk of an acute attack
SLC01B1 polymorphism	Statins	Increased risk of rhabdomyolysis
HLA-B*5701 polymorphism	Abacavir	Increased risk of skin hypersensitivity reaction
HLA-B*5801 polymorphism	Allopurinol	Increased risk of rashes in Han Chinese
HLA-B*1502 polymorphism	Carbamazepine	Increased risk of serious dermatological reactions (e.g. Stevens–Johnson syndrome)
Hepatic nuclear factor 1 alpha (HNF1A) polymorphism	Sulphonylureas	Increased sensitivity to the blood glucose-lowering effects
Human epidermal growth factor receptor 2 (HER2)-positive breast cancer cells	Trastuzumab	Increased sensitivity to the inhibitory effects on growth and division of the target cancer cells

reactions – these present in a similar manner to acute anaphylaxis, but are a consequence of non-IgE-mediated degranulation of mast cells and basophils or direct complement activation (e.g. aspirin, non-steroidal anti-inflammatory drugs, opiates). (3) Types II–IV hypersensitivity reactions – these occur via other mechanisms, such as antibody-dependent (IgM or IgG), immune complex-mediated or cell-mediated pathways (p. 78); examples of such reactions are listed in Box 2.6.

- *Drug toxicity.* Adverse effects of a drug that occur because the dose or plasma concentration has risen above the therapeutic range, either unintentionally or intentionally (drug overdose; see Fig. 2.2 and p. 224).
- *Drug misuse.* The misuse of recreational or therapeutic drugs that may lead to addiction or dependence, serious physiological injury (such as liver damage), psychological harm (abnormal behaviour patterns, hallucinations, memory loss) or death (p. 1240).

### Prevalence of ADRs

ADRs are a common cause of illness, accounting in the UK for approximately 3% of consultations in primary care, 7% of emergency admissions to hospital and affecting around 15% of hospital inpatients. Many 'disease' presentations are eventually attributed to ADRs, emphasising the importance of always taking a careful drug history (Box 2.7). Factors

accounting for the rising prevalence of ADRs are the increasing age of patients, polypharmacy (higher risk of drug interactions), increasing availability of over-the-counter medicines, increasing use of herbal or traditional medicines and the increase in medicines available via the Internet that can be purchased without a prescription from a health-care professional. Risk factors for ADRs are shown in Box 2.8.

ADRs are important because they reduce quality of life for patients, reduce adherence to and therefore efficacy of beneficial treatments, cause diagnostic confusion, undermine the confidence of patients in their health-care professional(s) and consume health-care resources.

Retrospective analysis of ADRs has shown that more than half could have been avoided if the prescriber had taken more care in anticipating the potential hazards of drug therapy. For example, non-steroidal anti-inflammatory drug (NSAID) use accounts for many thousands of emergency admissions, gastrointestinal bleeding episodes and a significant number of deaths. In many cases, the patients are at increased risk due to their age, interacting drugs (e.g. aspirin, warfarin) or a past history of peptic ulcer disease. Drugs that commonly cause ADRs are listed in Box 2.9.

Prescribers and their patients ideally want to know the frequency with which ADRs occur for a specific drug. Although this may be well characterised for more common ADRs observed in clinical trials, it is less clear for rarely reported ADRs when the total numbers of reactions and patients exposed are not known. The words used to describe frequency

## 2.6 Examples of drug-mediated types I-IV hypersensitivity reactions<sup>1</sup>

### Type I (mediated by IgE antibodies and mast cell degranulation)

Acute anaphylaxis

- Penicillins
- Chemotherapy
- Monoclonal antibodies
- Neuromuscular blocking drugs

### Type II (mediated by IgM and IgG antibodies)

Haemolytic anaemia (latency less than 7 days)

- Methyldopa
- Penicillins
- Cephalosporins
- NSAIDs
- Quinidine/quinine

Neutropenia/agranulocytosis (latency days to weeks)

- Antiarrhythmics
- Antibiotics
- NSAIDs
- Antimalarials
- Antithyroid drugs
- Clozapine
- Ticlopidine

Thrombocytopenia (latency 1–2 weeks)

- Carbamazepine
- Heparin
- Penicillins
- Cephalosporins
- NSAIDs
- Quinidine/quinine
- Thiazide diuretics

### Type III (mediated by immune complex deposition)

Glomerulonephritis, serum sickness, vasculitis

- Penicillins
- Cephalosporins
- Sulphonamides

### Type IV (mediated by T cells)

Skin eruptions, including maculopapular rash, lichenoid or pemphigoid-like reaction, drug rash with eosinophilia and systemic symptoms (DRESS), Stevens–Johnson syndrome (SJS), toxic epidermal necrolysis (TEN)<sup>2</sup>

- Carbamazepine
- Abacavir
- Trimethoprim
- Dapsone

Drug-induced lupus

- Allopurinol
- Thiazide diuretics
- Hydralazine

<sup>1</sup>Type I is often known as 'immediate' hypersensitivity while types II–IV are known as 'delayed' hypersensitivity. <sup>2</sup>See also Boxes 27.34 and 27.35.

can be misinterpreted by patients, but widely accepted meanings include: very common (10% or more), common (1%–10%), uncommon (0.1%–1%), rare (0.01%–0.1%) and very rare (0.01% or less).

## Classification of ADRs

ADRs have traditionally been classified into two major groups:

- *Type A ('augmented')* ADRs. These are predictable from the known pharmacodynamic effects of the drug and are dose-dependent, common (detected early in drug development) and usually mild. Examples include constipation caused by opioids, hypotension caused by antihypertensives and dehydration caused by diuretics.
- *Type B ('bizarre')* ADRs. These are not predictable, are not obviously dose-dependent in the therapeutic range, are rare (remaining undiscovered until the drug is marketed) and often severe. Patients

## 2.7 How to take a drug history

### Information from the patient (or carer)

Use language that patients will understand (e.g. 'medicines' rather than 'drugs', which may be mistaken for drugs of abuse) while gathering the following information:

- Current prescribed drugs, including formulations (e.g. modified-release tablets), doses, routes of administration, frequency and timing, duration of treatment
- Other medications that are often forgotten (e.g. contraceptives, over-the-counter drugs, herbal remedies, vitamins)
- Drugs that have been taken in the recent past and reasons for stopping them
- Previous drug hypersensitivity reactions, their nature and time course (e.g. rash, anaphylaxis)
- Previous ADRs, their nature and time course (e.g. ankle oedema with amlodipine)
- Adherence to therapy (e.g. 'Are you taking your medication regularly?')

### Information from GP medical records and/or pharmacist

- Up-to-date list of medications
- Previous ADRs
- Last order dates for each medication

### Inspection of medicines

- Drugs and their containers (e.g. blister packs, bottles, vials) should be inspected for name, dosage and the number of dosage forms taken since dispensed

(ADR = adverse drug reaction)

## 2.8 Risk factors for adverse drug reactions

### Patient factors

- Advanced age (e.g. low physiological reserve)
- Gender (e.g. ACE inhibitor-induced cough in women)
- Polypharmacy (e.g. drug interactions)
- Genetic predisposition (see Box 2.5)
- Hypersensitivity/allergy (e.g.  $\beta$ -lactam antibiotics)
- Diseases altering pharmacokinetics (e.g. hepatic or renal impairment) or pharmacodynamic responses (e.g. bladder instability)
- Adherence problems (e.g. cognitive impairment)

### Drug factors

- Steep dose–response curve (e.g. insulin)
- Low therapeutic index (e.g. digoxin, cytotoxic drugs)

### Prescriber factors

- Inadequate understanding of the principles of clinical pharmacology
- Inadequate knowledge of the patient
- Inadequate knowledge of the prescribed drug
- Inadequate instructions and warnings provided to patients
- Inadequate monitoring arrangements planned

(ACE = angiotensin-converting enzyme)

who experience type B reactions are generally 'hyper-susceptible' because of unpredictable immunological or genetic factors (e.g. anaphylaxis caused by penicillin, peripheral neuropathy caused by isoniazid in poor acetylators).

This simple classification has shortcomings, and a more detailed classification based on dose (see Fig. 2.2), timing and susceptibility (DoTS) is now used by those analysing ADRs in greater depth (Box 2.10). The AB classification can be extended as a reminder of some other types of ADR:

- *Type C ('chronic/continuous')* ADRs. These occur only after prolonged continuous exposure to a drug. Examples include osteoporosis caused by glucocorticoids, retinopathy caused by (hydroxy) chloroquine and tardive dyskinesia caused by phenothiazines.
- *Type D ('delayed')* ADRs. These are delayed until long after drug exposure, making diagnosis difficult. Examples include malignancies that may emerge after immunosuppressive treatment post-transplantation (e.g. azathioprine, tacrolimus) and vaginal cancer occurring many years after exposure to diethylstilboestrol.
- *Type E ('end-of-treatment')* ADRs. These occur after abrupt drug withdrawal (see Box 2.3).

2.9 Drugs that are common causes of adverse drug reactions	
Drug or drug class	Common adverse drug reactions
<b>ACE inhibitors</b> (e.g. lisinopril)	Renal impairment Hyperkalaemia
<b>Antibiotics</b> (e.g. amoxicillin)	Nausea Diarrhoea
<b>Anticoagulants</b> (e.g. warfarin, heparin)	Bleeding
<b>Antipsychotics</b> (e.g. haloperidol)	Falls Sedation Delirium
<b>Aspirin</b>	Gastrotoxicity (dyspepsia, gastrointestinal bleeding)
<b>Benzodiazepines</b> (e.g. diazepam)	Drowsiness Falls
<b>β-blockers</b> (e.g. atenolol)	Cold peripheries Bradycardia
<b>Calcium channel blockers</b> (e.g. amlodipine)	Ankle oedema
<b>Digoxin</b>	Nausea and anorexia Bradycardia
<b>Diuretics</b> (e.g. furosemide, bendroflumethiazide)	Dehydration Electrolyte disturbance (hypokalaemia, hyponatraemia) Hypotension Renal impairment
<b>Insulin</b>	Hypoglycaemia
<b>NSAIDs</b> (e.g. ibuprofen)	Gastrotoxicity (dyspepsia, gastrointestinal bleeding) Renal impairment
<b>Opioid analgesics</b> (e.g. morphine)	Nausea and vomiting Delirium Constipation

(ACE = angiotensin-converting enzyme; NSAID = non-steroidal anti-inflammatory drug)

A teratogen is a drug with the potential to affect the development of the fetus in the first 10 weeks of intrauterine life (e.g. phenytoin, warfarin). The thalidomide disaster in the early 1960s highlighted the risk of teratogenicity and led to mandatory testing of all new drugs. Congenital defects in a live infant or aborted fetus should provoke suspicion of an ADR and a careful exploration of maternal drug exposures (including self-medication and herbal remedies).

## Detecting ADRs – pharmacovigilance

Type A ADRs become apparent early in the development of a new drug. By the time a new drug is licensed and launched on to a possible worldwide market, however, a relatively small number of patients (just several hundred) may have been exposed to it, meaning that rarer but potentially serious type B ADRs may remain undiscovered. Pharmacovigilance is the process of detecting ('signal generation') and evaluating ADRs in order to help prescribers and patients to be better informed about the risks of drug therapy. Drug regulatory agencies may respond to this information by placing restrictions on the licensed indications, reducing the recommended dose range, adding special warnings and precautions for prescribers in the product literature, writing to all health-care professionals or withdrawing the product from the market.

Voluntary reporting systems allow health-care professionals and patients to report suspected ADRs to the regulatory authorities. A good example is the 'Yellow Card' scheme that was set up in the UK

2.10 DoTS classification of adverse drug reactions	
Category	Example
<b>Dose</b>	
Below therapeutic dose	Anaphylaxis with penicillin
In the therapeutic dose range	Nausea with morphine
At high doses	Hepatotoxicity with paracetamol
<b>Timing</b>	
With the first dose	Anaphylaxis with penicillin
Early stages of treatment	Hyponatraemia with diuretics
On stopping treatment	Benzodiazepine withdrawal syndrome
Significantly delayed	Clear-cell cancer with diethylstilboestrol
<b>Susceptibility</b>	See patient factors in Box 2.8

2.11 TREND analysis of suspected adverse drug reactions		
Factor	Key question	Comment
Temporal relationship	What is the time interval between the start of drug therapy and the reaction?	Most ADRs occur soon after starting treatment and within hours in the case of anaphylactic reactions
Re-challenge	What happens when the patient is re-challenged with the drug?	Re-challenge is rarely possible because of the need to avoid exposing patients to unnecessary risk
Exclusion	Have concomitant drugs and other non-drug causes been excluded?	ADR is a diagnosis of exclusion following clinical assessment and relevant investigations for non-drug causes
Novelty	Has the reaction been reported before?	The suspected ADR may already be recognised and mentioned in the SPC approved by the regulatory authorities
De-challenge	Does the reaction improve when the drug is withdrawn or the dose is reduced?	Most, but not all, ADRs improve on drug withdrawal, although recovery may be slow

(ADR = adverse drug reaction; SPC = summary of product characteristics)

in response to the thalidomide tragedy. Reports are analysed to assess the likelihood that they represent a true ADR (Box 2.11). Although voluntary reporting is a continuously operating and effective early-warning system for previously unrecognised rare ADRs, its weaknesses include low reporting rates (only 3% of all ADRs and 10% of serious ADRs are ever reported), an inability to quantify risk (because the ratio of ADRs to prescriptions is unknown) and the influence of prescriber awareness on likelihood of reporting (reporting rates rise rapidly following publicity about potential ADRs).

More systematic approaches to collecting information on ADRs include 'prescription event monitoring', in which a sample of prescribers of a particular drug are issued with questionnaires concerning the clinical outcome for their patients and the collection of population statistics. Many health-care systems routinely collect patient-identifiable data on prescriptions (a surrogate marker of exposure to a drug), health-care events (e.g. hospitalisation, operations, new clinical diagnoses) and other

clinical data (e.g. haematology, biochemistry). If these records can be linked, with appropriate safeguards for confidentiality and data protection, they may provide a much more powerful mechanism for assessing both the harms and benefits of drugs.

All prescribers will inevitably see patients experiencing ADRs caused by prescriptions written by themselves or their colleagues. It is important that these are recognised early. In addition to the features in Box 2.11, features that should raise suspicion of an ADR and the need to respond (by drug withdrawal, dosage reduction or reporting to the regulatory authorities) include:

- concern expressed by a patient that a drug has harmed them
- abnormal clinical measurements (e.g. blood pressure, temperature, pulse, blood glucose and weight) or laboratory results (e.g. abnormal liver or renal function, low haemoglobin or white cell count) while on drug therapy
- new therapy started that could be in response to an ADR (e.g. omeprazole, allopurinol, naloxone)
- the presence of risk factors for ADRs (see Box 2.8).

## Drug interactions

A drug interaction has occurred when the administration of one drug increases or decreases the beneficial or adverse responses to another drug. Although the number of potential interacting drug combinations is very large, only a small number are common in clinical practice. Important drug interactions are most likely to occur when the affected drug has a low therapeutic index, steep dose–response curve, high first-pass or saturable metabolism, or a single mechanism of elimination.

### Mechanisms of drug interactions

Pharmacodynamic interactions occur when two drugs produce additive, synergistic or antagonistic effects at the same drug target (e.g. receptor, enzyme) or physiological system (e.g. electrolyte excretion, heart rate). These are the most common interactions in clinical practice and some important examples are given in Box 2.12.

### 2.12 Common drug interactions

Mechanism	Object drug	Precipitant drug	Result
<b>Pharmaceutical*</b>			
<b>Chemical reaction</b>	Sodium bicarbonate	Calcium gluconate	Precipitation of insoluble calcium carbonate
<b>Pharmacokinetic</b>			
<b>Reduced absorption</b>	Tetracyclines	Calcium, aluminium and magnesium salts	Reduced tetracycline absorption
<b>Reduced protein binding</b>	Phenytoin	Aspirin	Increased unbound and reduced total phenytoin plasma concentration
<b>Reduced metabolism:</b>			
CYP3A4	Amiodarone	Grapefruit juice	Cardiac arrhythmias because of prolonged QT interval (p. 418)
	Warfarin	Clarithromycin	Enhanced anticoagulation
CYP2C19	Phenytoin	Miconazole	Phenytoin toxicity
CYP2D6	Haloperidol	Fluoxetine	Haloperidol toxicity
Xanthine oxidase	Azathioprine	Allopurinol	Azathioprine toxicity
Monoamine oxidase	Catecholamines	Monoamine oxidase inhibitors	Hypertensive crisis due to monoamine toxicity
<b>Increased metabolism</b> (enzyme induction)	Ciclosporin	St John's wort	Loss of immunosuppression
<b>Reduced renal elimination</b>	Lithium	Diuretics	Lithium toxicity
	Methotrexate	NSAIDs	Methotrexate toxicity
<b>Pharmacodynamic</b>			
<b>Direct antagonism</b> at same receptor	Opioids	Naloxone	Reversal of opioid effects used therapeutically
	Salbutamol	Atenolol	Inhibits bronchodilator effect
<b>Direct potentiation</b> in same organ system	Benzodiazepines	Alcohol	Increased sedation
	ACE inhibitors	NSAIDs	Increased risk of renal impairment
<b>Indirect potentiation</b> by actions in different organ systems	Digoxin	Diuretics	Digoxin toxicity enhanced because of hypokalaemia
	Warfarin	Aspirin, NSAIDs	Increased risk of bleeding because of gastrotoxicity and antiplatelet effects
	Diuretics	ACE inhibitors	Blood pressure reduction (may be therapeutically advantageous) because of the increased activity of the renin–angiotensin system in response to diuresis

\*Pharmaceutical interactions are related to the formulation of the drugs and occur before drug absorption. (ACE = angiotensin-converting enzyme; NSAID = non-steroidal anti-inflammatory drug)

Pharmacokinetic interactions occur when the administration of a second drug alters the concentration of the first at its site of action. There are numerous potential mechanisms:

- **Absorption interactions.** Drugs that either delay (e.g. anticholinergic drugs) or enhance (e.g. prokinetic drugs) gastric emptying influence the rate of rise in plasma concentration of other drugs, but not the total amount of drug absorbed. Drugs that bind to form insoluble complexes or chelates (e.g. aluminium-containing antacids binding with ciprofloxacin) can reduce drug absorption.
- **Distribution interactions.** Co-administration of drugs that compete for protein binding in plasma (e.g. phenytoin and diazepam) can increase the unbound drug concentration, but the effect is usually short-lived due to increased elimination and hence restoration of the pre-interaction equilibrium.
- **Metabolism interactions.** Many drugs rely on metabolism by different isoenzymes of cytochrome P450 (CYP) in the liver. CYP enzyme inducers (e.g. phenytoin, rifampicin) generally reduce plasma concentrations of other drugs, although they may enhance activation of prodrugs. CYP enzyme inhibitors (e.g. clarithromycin, cimetidine, grapefruit juice) have the opposite effect. Enzyme induction effects usually take a few days to manifest because of the need to synthesise new CYP enzyme, in contrast to the rapid effects of enzyme inhibition.
- **Excretion interactions.** These primarily affect renal excretion. For example, drug-induced reduction in glomerular filtration rate (e.g. diuretic-induced dehydration, angiotensin-converting enzyme (ACE) inhibitors, NSAIDs) can reduce the clearance and increase the plasma concentration of many drugs, including some with a low therapeutic index (e.g. digoxin, lithium, aminoglycoside antibiotics). Less commonly, interactions may be due to competition for a common tubular organic anion transporter (e.g. methotrexate excretion may be inhibited by competition with NSAIDs).

## Avoiding drug interactions

Drug interactions are increasing as patients are prescribed more medicines (polypharmacy). Prescribers can avoid the adverse consequences of drug–drug interactions by taking a careful drug history (see Box 2.7) before prescribing additional drugs, only prescribing for clear indications and taking special care when prescribing drugs with a narrow therapeutic index (e.g. warfarin). When prescribing an interacting drug is unavoidable, good prescribers will seek further information and anticipate the potential risk. This will allow them to provide special warnings for the patient and arrange for monitoring, either of the clinical effects (e.g. coagulation tests for warfarin) or of plasma concentration (e.g. digoxin).

## Medication errors

A medication error is any *preventable* event that may lead to inappropriate medication use or patient harm while the medication is in the control of the health-care professional or patient. Errors may occur in prescribing, dispensing, preparing solutions, administration or monitoring. Many ADRs are considered in retrospect to have been ‘avoidable’ with more care or forethought; in other words, an adverse event considered by one prescriber to be an unfortunate ADR might be considered by another to be a prescribing error.

Medication errors are very common. Several thousand medication orders are dispensed and administered each day in a medium-sized hospital. Recent UK studies suggest that 7%–9% of hospital prescriptions contain an error, and most are written by junior doctors. Common prescribing errors in hospitals include omission of medicines (especially failure to prescribe regular medicines at the point of admission or discharge, i.e. ‘medicines reconciliation’), dosing errors, unintentional prescribing and poor use of documentation (Box 2.13).

Most prescription errors result from a combination of failures by the individual prescriber and the health-service systems in which they work

## 2.13 Hospital prescribing errors

Error type	Approximate % of total
Omission on admission	30
Underdose	11
Overdose	8
Strength/dose missing	7
Omission on discharge	6
Administration times incorrect/missing	6
Duplication	6
Product or formulation not specified	4
Incorrect formulation	4
No maximum dose	4
Unintentional prescribing	3
No signature	2
Clinical contraindication	1
Incorrect route	1
No indication	1
Intravenous instructions incorrect/missing	1
Drug not prescribed but indicated	1
Drug continued for longer than needed	1
Route of administration missing	1
Start date incorrect/missing	1
Risk of drug interaction	< 0.5
Controlled drug requirements incorrect/missing	< 0.5
Daily dose divided incorrectly	< 0.5
Significant allergy	< 0.5
Drug continued in spite of adverse effects	< 0.5
Premature discontinuation	< 0.5
Failure to respond to out-of-range drug level	< 0.5

(Box 2.14). Health-care organisations increasingly encourage reporting of errors within a ‘no-blame culture’ so that they can be subject to ‘root cause analysis’ using human error theory (Fig. 2.5). Prevention is targeted at the factors in Box 2.14 and can be supported by prescribers communicating and cross-checking with colleagues (e.g. when calculating doses adjusted for body weight, or planning appropriate monitoring after drug administration). Prescription errors may also be reduced by clinical pharmacist support (e.g. to check the patient’s previous medications and current prescriptions) and electronic prescribing (which avoids errors due to illegibility or serious dosing mistakes and may be combined with a clinical decision support system to take account of patient characteristics and drug history, and provide warnings of potential contraindications and drug interactions).

## Responding when an error is discovered

All prescribers will make errors. When they do, their first duty is to protect the patient’s safety. This will involve a clinical review and the taking of any steps that will reduce harm (e.g. remedial treatment, monitoring, recording the event in the notes, informing colleagues). Patients should be informed if they have been exposed to potential harm. For errors that do not reach the patient, it is the prescriber’s duty to report them, so that others can learn from the experience and take the opportunity to reflect on how a similar incident might be avoided in the future.

## 2.14 Causes of prescribing errors

### Systems factors

- Working hours of prescribers (and others)
- Patient throughput
- Professional support and supervision by colleagues
- Availability of information (medical records)
- Design of prescription forms
- Distractions
- Availability of decision support
- Checking routines (e.g. clinical pharmacy)
- Reporting and reviewing of incidents

### Prescriber factors

#### Knowledge

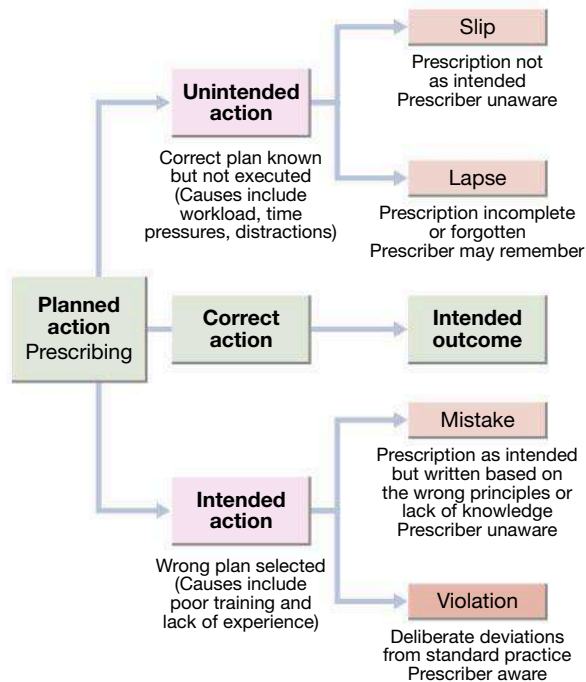

- Clinical pharmacology principles
- Drugs in common use
- Therapeutic problems commonly encountered
- Knowledge of workplace systems

#### Skills

- Taking a good drug history
- Obtaining information to support prescribing
- Communicating with patients
- Numeracy and calculations
- Prescription writing

#### Attitudes

- Coping with risk and uncertainty
- Monitoring of prescribing
- Checking routines

**Fig. 2.5 Human error theory.** Unintended errors may occur because the prescriber fails to complete the prescription correctly (a slip; e.g. writes the dose in 'mg' not 'micrograms') or forgets part of the action that is important for success (a lapse; e.g. forgets to co-prescribe folic acid with methotrexate); prevention requires the system to provide appropriate checking routines. Intended errors occur when the prescriber acts incorrectly due to lack of knowledge (a mistake; e.g. prescribes atenolol for a patient with known severe asthma because of ignorance about the contraindication); prevention must focus on training the prescriber.

## Drug regulation and management

Given the powerful beneficial and potentially adverse effects of drugs, the production and use of medicines are strictly regulated (e.g. by the Food

## 2.15 Clinical development of new drugs

### Phase I

- Healthy volunteers (20–80)
- These involve initial single-dose, 'first-into-man' studies, followed by repeated-dose studies. They aim to establish the basic pharmacokinetic and pharmacodynamic properties, and short-term safety
- Duration: 6–12 months

### Phase II

- Patients (100–200)
- These investigate clinical effectiveness ('proof of concept'), safety and dose–response relationship, often with a surrogate clinical endpoint, in the target patient group to determine the optimal dosing regimen for larger confirmatory studies
- Duration: 1–2 years

### Phase III

- Patients (100s–1000s)
- These are large, expensive clinical trials that confirm safety and efficacy in the target patient population, using relevant clinical endpoints. They may be placebo-controlled studies or comparisons with other active compounds
- Duration: 1–2 years

### Phase IV

- Patients (100s–1000s)
- These are undertaken after the medicine has been marketed for its first indication to evaluate new indications, new doses or formulations, long-term safety or cost-effectiveness

and Drug Administration in the United States, Medicines and Healthcare Products Regulatory Agency in the UK, and Central Drugs Standard Control Organisation in India). Regulators are responsible for licensing medicines, monitoring their safety (pharmacovigilance), approving clinical trials, and inspecting and maintaining standards of drug development and manufacture.

In addition, because of the high costs of drugs and their adverse effects, health-care services must prioritise their use in light of the evidence of their benefit and harm, a process referred to as 'medicines management'.

## Drug development and marketing

Naturally occurring products have been used to treat illnesses for thousands of years and some remain in common use today. Examples include morphine from the opium poppy (*Papaver somniferum*), digitalis from the foxglove (*Digitalis purpurea*), curare from the bark of a variety of species of South American trees, and quinine from the bark of the *Cinchona* species. Although plants and animals remain a source of discovery, the majority of new drugs come from drug discovery programmes that aim to identify small-molecule compounds with specific interactions with a molecular target that will induce a predicted biological effect.

The usual pathway for development of these small molecules includes: identifying a plausible molecular target by investigating pathways in disease; screening a large library of compounds for those that interact with the molecular target in vitro; conducting extensive medicinal chemistry to optimise the properties of lead compounds; testing efficacy and toxicity of these compounds in vitro and in animals; and undertaking a clinical development programme (Box 2.15). This process typically takes longer than 10 years and may cost up to US\$2 billion. Manufacturers have a defined period of exclusive marketing of the drug while it remains protected by an original patent, typically 10–15 years, during which time they must recoup the costs of developing the drug. Meanwhile, competitor companies will often produce similar 'me too' drugs of the same class. Once the drug's patent has expired, 'generic' manufacturers may step in to produce cheaper formulations of the drug. Paradoxically, if a generic drug is produced by only one manufacturer, the price may actually rise, sometimes substantially.

2.16 Novel therapeutic alternatives to conventional small-molecule drugs		
Approaches	Therapeutic indications	Challenges
<b>Monoclonal antibodies</b> Targeting of receptors or other molecules with relatively specific antibodies	Cancer Chronic inflammatory diseases (e.g. rheumatoid arthritis, inflammatory bowel disease)	Selectivity of action Complex manufacturing process
<b>Small interfering RNA (siRNA)</b> Inhibition of gene expression	Macular degeneration	Delivery to target
<b>Gene therapy</b> Delivery of modified genes that supplement or alter host DNA	Cystic fibrosis Cancer Cardiovascular disease	Delivery to target Adverse effects of delivery vector (e.g. virus)
<b>Stem cell therapy</b> Stem cells differentiate and replace damaged host cells	Parkinson's disease Spinal cord injury Ischaemic heart disease	Delivery to target Immunological compatibility Long-term effects unknown

### New therapeutic agents

The traditional approach of targeting membrane-bound receptors and enzymes with small molecules (see Box 2.2) is now giving way to drug development that focuses on new targets, such as complex second-messenger systems, cytokines, nucleic acids and cellular networks (Box 2.16). These require the development of novel therapeutic agents, which are typically large molecules (e.g. human recombinant antibodies) manufactured by biological processes ('biologics') (Fig. 2.6). These present new challenges for 'translational medicine', the discipline of converting scientific discoveries into a useful medicine with a well-defined benefit–risk profile, and also for health-care providers and prescribers.

### Manufacturers

There are multiple challenges at every stage of the development and quality assurance of high-quality biological products. These include the initial molecular cloning process, development of clone expression by stable cell lines, purification and characterisation procedures, performing post-translation modifications, ensuring chemical stability, deploying novel sensitive bio-analytical methods and meeting stringent regulatory expectations. There are also new hurdles to overcome in the clinical development phase, including definition of the clinical indication with linked inclusion and exclusion criteria, study design and appropriate comparator product, selecting the appropriate therapeutic dose based on interpretation of pharmacokinetic/pharmacodynamic (PK/PD) data, and addressing specific safety concerns (notably immunogenicity) that arise after exposure to large biological molecules.

### Health services

Biological drugs are often much more expensive than conventional synthetic molecules because of the complex manufacturing process outlined above, but also because they often have much narrower indications for use based on specific molecular profiling of the recipients. This means that the development costs have to be recouped from a relatively smaller patient group. After the patent for the originator product expires, other manufacturers may develop similar products ('biosimilars') that have the same pharmacological actions, but are not completely identical because of inevitable differences that arise during a complex manufacturing process (e.g. glycosylation). For that reason, 'biosimilars' are not considered to be 'generic' medications, although they are usually considerably cheaper than the originator product. Nevertheless, the use of expensive biological agents is subject to particular scrutiny with regard to cost-effectiveness and health services may put additional requirements in place prior to access (e.g. failure of conventional treatments).

### Prescribers

For prescribers there are some important considerations when assessing the balance of beneficial and adverse effects of biologics, for example, the use of recombinant antibodies for autoimmune inflammatory conditions. Drugs such as infliximab or adalimumab carry a significantly increased risk of infection when compared to classical disease-modifying anti-rheumatic drugs (cDMARDs) and this risk is increased by age, co-morbidities and concomitant use of other immunosuppressant drugs (e.g. glucocorticoids). Patients should be protected with appropriate vaccinations (e.g. influenza, pneumococcus) and treatment is contra-indicated in the presence of active infection (e.g. hepatitis B, tuberculosis). The increased immunogenicity of large biological molecules has two important consequences. First, there is an increased chance of immediate and delayed hypersensitivity reactions (see Box 2.6). Second, the development of anti-drug antibodies can precipitate loss of effect. A recent Cochrane review of exposure to nine commonly used biologics for up to 5 years concluded that there was a 5% absolute increase in all adverse effects combined, a 1% absolute increase in risk of serious infection, but little or no increased risk of cancer or other serious outcomes.

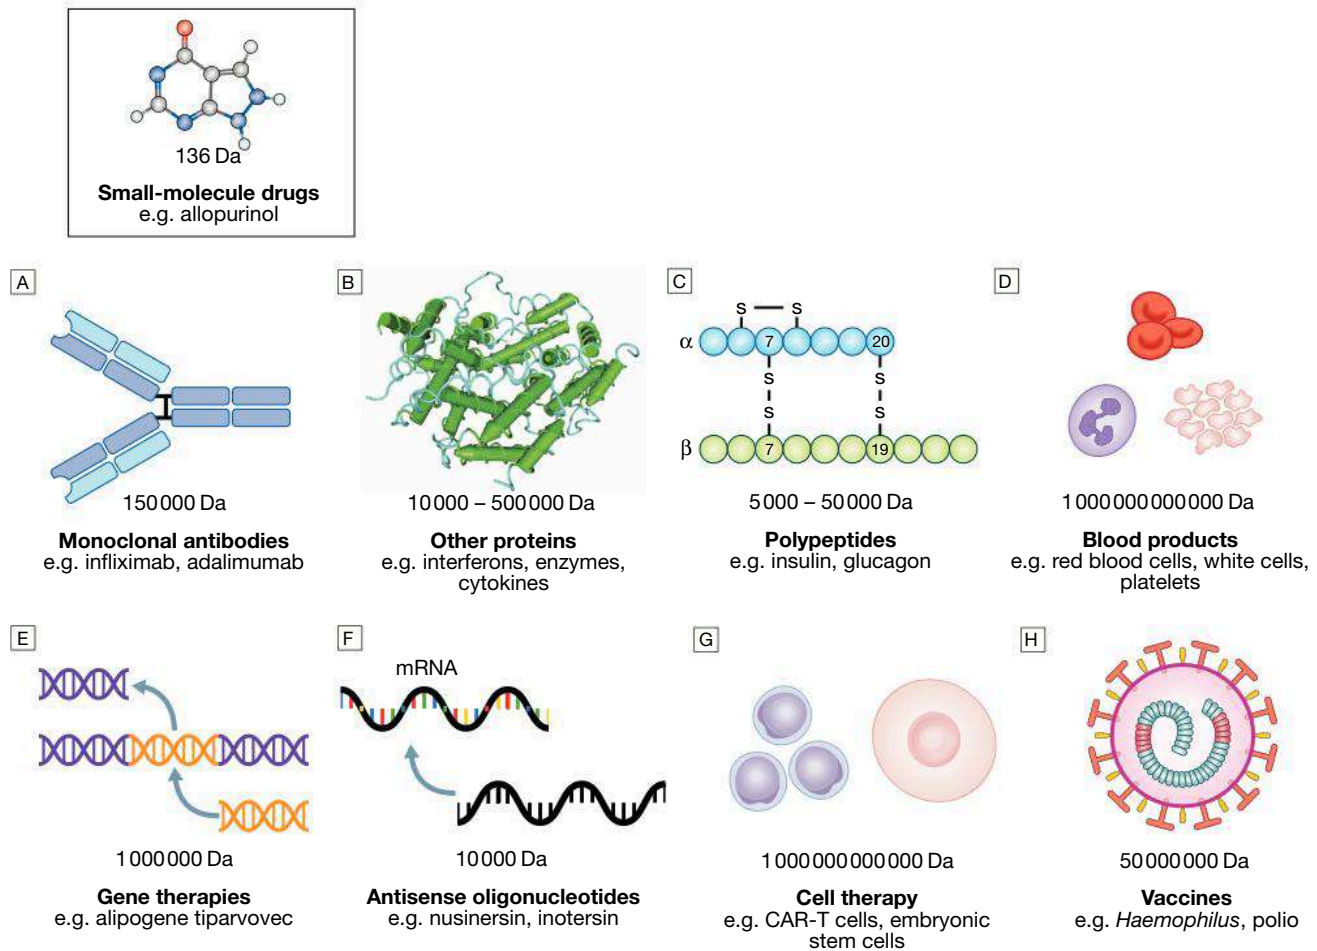

### Licensing new medicines

New drugs are given a 'market authorisation', based on the evidence of quality, safety and efficacy presented by the manufacturer. The regulator not only will approve the drug, but also will take great care to ensure that the accompanying information reflects the evidence that has been presented. The summary of product characteristics (SPC), or 'label', provides detailed information about indications, dosage, adverse effects, warnings and monitoring requirements. If approved, drugs can be made available with different levels of restriction:

- *Controlled drug (CD)*. These drugs are subject to strict legal controls on supply and possession, usually due to their abuse potential (e.g. opioid analgesics).
- *Prescription-only medicine (PoM)*. These are available only from a pharmacist and can be supplied only if prescribed by an appropriate practitioner.
- *Pharmacy (P)*. These are available only from a pharmacist, but can be supplied without a prescription.
- *General sales list (GSL)*. These medicines may be bought 'over the counter' (OTC) from any shop and without a prescription.

Although the regulators take great care to agree the exact indications for prescribing a medicine, based on the evidence provided by the manufacturer, there are some circumstances in which prescribers may

**Fig. 2.6** The mechanism of action and molecular weight of various types of biologic therapies. **A** Monoclonal antibodies are synthesised proteins that act like human antibodies in the immune system to sequester specific molecules involved in cell signalling (e.g. TNF- $\alpha$ ) or enhance the response to exogenous antigens. **B** Other proteins include analogues of cytokines involved in cell signalling and enzymes that increase the activity of metabolic pathways. **C** Polypeptides are typically analogues of endogenous peptide hormones. **D** Blood products are given as replacement for natural blood constituents. **E** Gene therapies are used to regulate, repair, replace, add to, or remove a nucleic acid sequence in native DNA. **F** Antisense oligonucleotides are short, synthetic, single-stranded oligodeoxynucleotides that can alter RNA and reduce, restore, or modify protein expression. **G** Cell therapies include injection of cells that replace damaged cells (e.g. embryonic stem cells) or manipulated immune cells that are targeted against cancer cells (e.g. CAR-T cells). **H** Vaccines are used to stimulate the immune system to respond to and remember specific antigens associated with viral or bacterial infections. (CAR-T cells = chimeric antigen recipient T cells; Da = Daltons; mRNA = messenger ribonucleic acid; TNF = tumour necrosis factor)

direct its use outside the terms stated in the SPC ('off-label' prescribing). Common situations where this might occur include prescribing outside the approved age group (e.g. prescribing for children) or using an alternative formulation (e.g. administering a medicine provided in a solid form as an oral solution). Other important examples might include prescribing for an indication for which there are no approved medicines or where all of the approved medicines have caused unacceptable adverse effects. Occasionally, medicines may be prescribed when there is no marketing authorisation in the country of use. Examples include when a medicine licensed in another country is imported for use for an individual patient ('unlicensed import') or when a patient requires a specific preparation of a medicine to be manufactured ('unlicensed special'). When prescribing is 'off-label' or 'unlicensed', there is an increased requirement for prescribers to be able to justify their actions and to inform and agree the decision with the patient.

## Drug marketing

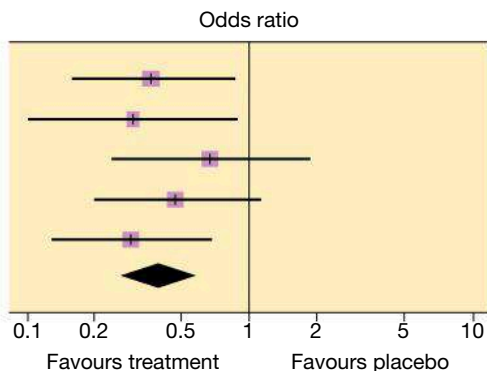

The marketing activities of the pharmaceutical industry are well resourced and are important in the process of recouping the massive costs of drug development. In some countries, such as the United States, it is possible to promote a new drug by direct-to-consumer advertising, although this is illegal in the UK and countries of the European Union. A major focus

is on promotion to prescribers via educational events, sponsorship of meetings, advertisements in journals, involvement with opinion leaders and direct contact by company representatives. Such largesse has the potential to cause significant conflicts of interest and might tempt prescribers to favour one drug over another, even in the face of evidence on effectiveness or cost-effectiveness.

## Managing the use of medicines

Many medicines meet the three key regulatory requirements of quality, safety and efficacy. Although prescribers are legally entitled to prescribe any of them, it is desirable to limit the choice so that treatments for specific diseases can be focused on the most effective and cost-effective options, prescribers (and patients) gain familiarity with a smaller number of medicines, and pharmacies can concentrate stocks on them.

The process of ensuring optimal use of available medicines is known as 'medicines management' or 'quality use of medicines'. It involves careful evaluation of the evidence of benefit and harm from using the medicine, an assessment of cost-effectiveness and support for processes to implement the resulting recommendations. These activities usually involve both national (e.g. National Institute for Health and Care Excellence (NICE) in the UK) and local organisations (e.g. drug and therapeutics committees).

**Fig. 2.7 Systematic review of the evidence from randomised controlled clinical trials.** This forest plot shows the effect of warfarin compared with placebo on the likelihood of stroke in patients with atrial fibrillation in five randomised controlled trials that passed the quality criteria required for inclusion in a meta-analysis. For each trial, the purple box is proportionate to the number of participants. The tick marks show the mean odds ratio and the black lines indicate its 95% confidence intervals. Note that not all the trials showed statistically significant effects (i.e. the confidence intervals cross 1.0). However, the meta-analysis, represented by the black diamond, confirms a highly significant statistical benefit. The overall odds ratio is approximately 0.4, indicating a mean 60% risk reduction with warfarin treatment in patients with the characteristics of the participants in these trials.

## Evaluating evidence

Drugs are often evaluated in high-quality randomised controlled trials, the results of which can be considered in systematic reviews (Fig. 2.7). Ideally, data are available not only for comparison with placebo, but also for 'head-to-head' comparison with alternative therapies. Trials are conducted in selected patient populations and so may not be representative of every clinical scenario; therefore, extrapolation to individual patients is not always straightforward. Other subtle bias may be introduced because of the sources of funding (e.g. pharmaceutical industry) and the interests of the investigators in being involved in research that has a 'positive' impact. These biases may be manifest in the way the trials are conducted or in how they are interpreted or reported. A common example of the latter is the difference between relative and absolute risk of clinical events reported in prevention trials. If a clinical event is encountered in the placebo arm at a rate of 1 in 50 patients (2%), but only 1 in 100 patients (1%) in the active treatment arm, then the impact of treatment can be described as either a 50% relative risk reduction or 1% absolute risk reduction. Although the former sounds more impressive, it is the latter that is of more importance to the individual patient. It means that the number of patients that needed to be treated (NNT) for 1 to benefit (compared to placebo) was 100. This illustrates how large clinical trials of new medicines can produce highly statistically significant and impressive relative risk reductions and still predict a very modest clinical impact.

## Evaluating cost-effectiveness

New drugs often represent an incremental improvement over the current standard of care, but are usually more expensive. Health-care budgets are limited in every country and so it is impossible to fund all new medicines. This means that very difficult financial decisions have to be taken with due regard to the principles of ethical justice. The main approach taken is cost-effectiveness analysis (CEA), where a comparison is made between the relative costs and outcomes of different courses of action. CEA is usually expressed as a ratio where the denominator is a gain in health and the numerator is the cost associated with the health gain. A major challenge is to compare the value of interventions for different clinical outcomes. One method is to calculate the quality-adjusted life years (QALYs) gained if the new drug is used rather than standard treatment. This analysis involves estimating the 'utility' of various health states between 1 (perfect health) and 0 (dead). If the additional costs and any savings are known, then it is

## 2.17 Cost-effectiveness analysis

A clinical trial lasting 2 years compares two interventions for the treatment of colon cancer:

- Treatment A: standard treatment, cost £1000/year, oral therapy
- Treatment B: new treatment, cost £6000/year, monthly intravenous infusions, often followed by a week of nausea.

The new treatment (B) significantly increases the average time to progression (18 months versus 12 months) and reduces overall mortality (40% versus 60%). The health economist models the survival curves from the trial in order to undertake a cost-utility analysis and concludes that:

- Intervention A: allows an average patient to live for 2 extra years at a utility 0.7 = 1.4 QALYs (cost £2000)
- Intervention B: allows an average patient to live for 3 extra years at a utility 0.6 = 1.8 QALYs (cost £18 000).

The health economists conclude that treatment B provides an extra 0.4 QALYs at an extra cost of £16 000, meaning that the ICER = £40 000/QALY. They recommend that the new treatment should not be funded on the basis that their threshold for cost acceptability is £30 000/QALY.

(ICER = incremental cost-effectiveness ratio; QALY = quality-adjusted life year)

possible to derive the incremental cost-effectiveness ratio (ICER) in terms of cost/QALY. These principles are exemplified in Box 2.17. There are, however, inherent weaknesses in this kind of analysis: it usually depends on modelling future outcomes well beyond the duration of the clinical trial data; it assumes that QALYs gained at all ages are of equivalent value; and the appropriate standard care against which the new drug should be compared is often uncertain.

These pharmacoeconomic assessments are challenging and resource-intensive, and are undertaken at national level in most countries, e.g. in the UK by NICE.

## Implementing recommendations

Many recommendations about drug therapy are included in clinical guidelines written by an expert group after systematic review of the evidence. Guidelines provide recommendations rather than obligations for prescribers and are helpful in promoting more consistent and higher-quality prescribing. They are often written without concern for cost-effectiveness, however, and may be limited by the quality of available evidence. Guidelines cannot anticipate the extent of the variation between individual patients who may, for example, have unexpected contraindications to recommended drugs or choose different priorities for treatment. When deviating from respected national guidance, prescribers should be able to justify their practice.

Additional recommendations for prescribing are often implemented locally or imposed by bodies responsible for paying for health care. Most health-care units have a drug and therapeutics committee (or equivalent) comprised of medical staff, pharmacists and nurses, as well as managers (because of the implications of the committee's work for governance and resources). This group typically develops local prescribing policy and guidelines, maintains a local drug formulary and evaluates requests to use new drugs. The local formulary contains a more limited list than any national formulary (e.g. *British National Formulary*) because the latter lists all licensed medicines that can be prescribed legally, while the former contains only those that the health-care organisation has approved for local use. The local committee may also be involved, with local specialists, in providing explicit protocols for management of clinical scenarios.

## Prescribing in practice

### Decision-making in prescribing

Prescribing should be based on a rational approach to a series of challenges (see Box 2.1).

## Making a diagnosis

Ideally, prescribing should be based on a confirmed diagnosis but, in reality, many prescriptions are based on the balance of probability, taking into account the differential diagnosis (e.g. proton pump inhibitors for post-prandial retrosternal discomfort).

## Establishing the therapeutic goal

The goals of treatment are usually clear, particularly when relieving symptoms (e.g. pain, nausea, constipation). Sometimes the goal is less obvious to the patient, especially when aiming to prevent future events (e.g. ACE inhibitors to prevent hospitalisation and extend life in chronic heart failure). Prescribers should be clear about the therapeutic goal against which they will judge success or failure of treatment. It is also important to establish that the value placed on this goal by the prescriber is shared by the patient (concordance).

## Choosing the therapeutic approach

For many clinical problems, drug therapy is not absolutely mandated. Having taken the potential benefits and harms into account, prescribers must consider whether drug therapy is in the patient's interest and is preferred to no treatment or one of a range of alternatives (e.g. physiotherapy, psychotherapy, surgery). Assessing the balance of benefit and harm is often complicated and depends on various features associated with the patient, disease and drug (Box 2.18).

## Choosing a drug

For most common clinical indications (e.g. type 2 diabetes, depression), more than one drug is available, often from more than one drug class. Although prescribers often have guidance about which represents the rational choice for the average patient, they still need to consider whether this is the optimal choice for the individual patient. Certain factors may influence the choice of drug:

### Absorption

Patients may find some formulations easier to swallow than others or may be vomiting and require a drug available for parenteral administration.

### Distribution

Distribution of a drug to a particular tissue sometimes dictates choice (e.g. tetracyclines and rifampicin are concentrated in the bile, and lincocmycin and clindamycin in bones).

### Metabolism

Drugs that are extensively metabolised should be avoided in severe liver disease (e.g. opioid analgesics).

### Excretion

Drugs that depend on renal excretion for elimination (e.g. digoxin, aminoglycoside antibiotics) should be avoided in patients with impaired renal function if suitable alternatives exist.

### Efficacy

Prescribers normally choose drugs with the greatest efficacy in achieving the goals of therapy (e.g. proton pump inhibitors rather than H<sub>2</sub>-receptor

antagonists). It may be appropriate, however, to compromise on efficacy if other drugs are more convenient, safer to use or less expensive.

### Avoiding adverse effects

Prescribers should be wary of choosing drugs that are more likely to cause adverse effects (e.g. cephalosporins rather than alternatives for patients allergic to penicillin) or worsen coexisting conditions (e.g.  $\beta$ -blockers as treatment for angina in patients with asthma).

### Features of the disease

This is most obvious when choosing antibiotic therapy, which should be based on the known or suspected sensitivity of the infective organism.

### Severity of disease

The choice of drug should be appropriate to disease severity (e.g. paracetamol for mild pain, morphine for severe pain).

### Coexisting disease

This may be either an indication or a contraindication to therapy. Hypertensive patients might be prescribed a  $\beta$ -blocker if they also have left ventricular impairment, but not if they have asthma.

### Avoiding adverse drug interactions

Prescribers should avoid giving combinations of drugs that might interact, either directly or indirectly (see Box 2.12).

### Patient adherence to therapy

Prescribers should choose drugs with a simple dosing schedule or easier administration (e.g. the ACE inhibitor lisinopril once daily rather than captopril 3 times daily for hypertension).

### Cost

Prescribers should choose the cheaper drug (e.g. a generic or biosimilar) if two drugs are of equal efficacy and safety. Even if cost is not a concern for the individual patient, it is important to remember that unnecessary expenditure will ultimately limit choices for other prescribers and patients. Sometimes a more costly drug may be appropriate (e.g. if it yields improved adherence).

### Genetic factors

There are already a small number of examples where genotype influences the choice of drug therapy (see Box 2.5).

## Choosing a dosage regimen

Prescribers have to choose a dose, route and frequency of administration (dosage regimen) to achieve a steady-state drug concentration that provides sufficient exposure of the target tissue without producing toxic effects. Manufacturers draw up dosage recommendations based on average observations in many patients, but the optimal regimen that will maximise the benefit to harm ratio for an individual patient is never certain. Rational prescribing involves treating each prescription as an experiment and gathering sufficient information to amend it if necessary. There are some general principles that should be followed, as described below.

### Dose titration

Prescribers should generally start with a low dose and titrate this slowly upwards as necessary. This cautious approach is particularly important if the patient is likely to be more sensitive to adverse pharmacodynamic effects (e.g. delirium or postural hypotension in the elderly), if there may be altered pharmacokinetic handling (e.g. renal or hepatic impairment) and when using drugs with a low therapeutic index (e.g. benzodiazepines, lithium, digoxin). However, there are some exceptions. Some drugs must achieve therapeutic concentration quickly because of the clinical circumstance (e.g. antibiotics, glucocorticoids, carbimazole). When early effect is important, but there may be a delay in achieving steady state because of a drug's long half-life (e.g. digoxin, warfarin, amiodarone), an initial loading dose is given prior to establishing the appropriate maintenance dose (see Fig. 2.4).

### 2.18 Factors to consider when balancing benefits and harms of drug therapy

- Seriousness of the disease or symptom
- Efficacy of the drug
- Seriousness of potential adverse effects
- Likelihood of adverse effects
- Efficacy of alternative drugs or non-drug therapies
- Safety of alternative drugs or non-drug therapies

2.19 Factors influencing the route of drug administration	
Reason	Example
<b>Only one route possible</b>	Dobutamine (IV) Gliclazide (oral)
<b>Patient adherence</b>	Phenothiazines and thioxanthenes (2 weekly IM depot injections rather than daily tablets, in schizophrenia)
<b>Poor absorption</b>	Furosemide (IV rather than oral, in severe heart failure)
<b>Rapid action</b>	Haloperidol (IM rather than oral, in acute behavioural disturbance)
<b>Vomiting</b>	Phenothiazines (PR or buccal rather than oral, in nausea)
<b>Avoidance of first-pass metabolism</b>	Glyceryl trinitrate (SL, in angina pectoris)
<b>Certainty of effect</b>	Amoxicillin (IV rather than oral, in acute chest infection)
<b>Direct access to the site of action (avoiding unnecessary systemic exposure)</b>	Bronchodilators (INH rather than oral, in asthma) Local application of drugs to skin, eyes etc.
<b>Ease of access</b>	Diazepam (PR, if IV access is difficult in status epilepticus) Adrenaline (epinephrine) (IM, if IV access is difficult in acute anaphylaxis)
<b>Comfort</b>	Morphine (SC rather than IV in terminal care)

(IM = intramuscular; INH = by inhalation; IV = intravenous; PR = per rectum; SC = subcutaneous; SL = sublingual)

If adverse effects occur, the dose should be reduced or an alternative drug prescribed; in some cases, a lower dose may suffice if it can be combined with another synergistic drug (e.g. the immunosuppressant azathioprine reduces glucocorticoid requirements in patients with inflammatory disease). It is important to remember that the shape of the dose–response curve (see Fig. 2.2) means that higher doses may produce little added therapeutic effect and might increase the chances of toxicity.

### Route

There are many reasons for choosing a particular route of administration (Box 2.19).

### Frequency

Frequency of doses is usually dictated by a manufacturer's recommendation. Less frequent doses are more convenient for patients, but result in greater fluctuation between peaks and troughs in drug concentration (see Fig. 2.4). This is relevant if the peaks are associated with adverse effects (e.g. dizziness with antihypertensives) or the troughs are associated with troublesome loss of effect (e.g. anti-Parkinsonian drugs). These problems can be tackled either by splitting the dose or by employing a modified-release formulation, if available.

### Timing

For many drugs the time of administration is unimportant. There are occasionally pharmacokinetic or therapeutic reasons, however, for giving drugs at particular times (Box 2.20).

### Formulation

For some drugs there is a choice of formulation, some for use by different routes. Some are easier to ingest, particularly by children (e.g. elixirs). The formulation is important when writing repeat prescriptions for drugs with

a low therapeutic index that come in different formulations (e.g. lithium, phenytoin, theophylline). Even if the prescribed dose remains constant, an alternative formulation may differ in its absorption and bioavailability, and hence plasma drug concentration. These are examples of the small number of drugs that should be prescribed by specific brand name rather than 'generic' international non-proprietary name (INN).

### Duration

Some drugs require a single dose (e.g. thrombolysis post-myocardial infarction), while for others the duration of the course of treatment is certain at the outset (e.g. antibiotics). For most, the duration will be largely at the prescriber's discretion and will depend on response and disease progression (e.g. analgesics, antidepressants). For many, the treatment will be long-term (e.g. insulin, antihypertensives, levothyroxine).

## Involving the patient

Patients should, whenever possible, be engaged in making choices about drug therapy. Their beliefs and expectations affect the goals of therapy and help in judging the acceptable benefit/harm balance when selecting treatments. Very often, patients may wish to defer to the professional expertise of the prescriber. Nevertheless, they play key roles in adherence to therapy and in monitoring treatment, not least by providing early warning of adverse events. It is important for them to be provided with the necessary information to understand the choice that has been made, what to expect from the treatment, and any measurements that must be undertaken (Box 2.21).

A major drive to include patients has been the recognition that up to half of the drug doses for chronic preventative therapy are not taken. This is often termed 'non-compliance', but is more appropriately called 'non-adherence', to reflect a less paternalistic view of the doctor–patient relationship; it may or may not be intentional. Non-adherence to the dose regimen reduces the likelihood of benefits to the patient and can be costly in terms of wasted medicines and unnecessary health-care episodes. An important reason may be lack of concordance with the prescriber about the goals of treatment. A more open and shared decision-making process might resolve any misunderstandings at the outset and foster improved adherence, as well as improved satisfaction with health-care services and confidence in prescribers. Considerable efforts are now made to help patients to access the reliable information they require to engage more fully with clinicians. Patient-focused websites and leaflets provided by national services, local health-care providers and charities are increasingly supplementing the Patient Information Leaflet (PIL) approved by the regulatory authorities and supplied with all medicines. Fully engaging patients in shared decision-making is sometimes constrained by various factors, such as limited consultation time, language barriers and challenges in communicating complex numerical data.

## Writing the prescription

The culmination of the planning described above is writing an accurate and legible prescription so that the drug will be dispensed and administered as planned (see 'Writing prescriptions' below).

## Monitoring treatment effects

Rational prescribing involves monitoring for the beneficial and adverse effects of treatment so that the balance remains in favour of a positive outcome (see 'Monitoring drug therapy' below).

## Stopping drug therapy

It is also important to review long-term treatment at regular intervals to assess whether continued treatment is required. Elderly patients are keen to reduce their medication burden and are often prepared to compromise on the original goals of long-term preventative therapy to achieve this.

### 2.20 Factors influencing the timing of drug therapy

Drug	Recommended timing	Reasons
<b>Diuretics</b> (e.g. furosemide)	Once in the morning	Night-time diuresis undesirable
<b>Statins</b> (e.g. simvastatin)	Once at night	HMG CoA reductase activity is greater at night
<b>Antidepressants</b> (e.g. amitriptyline)	Once at night	Allows adverse effects to occur during sleep
<b>Salbutamol</b>	Before exercise	Reduces symptoms in exercise-induced asthma
<b>Glyceryl trinitrate</b>	When required	Relief of acute symptoms only
<b>Paracetamol</b>		
<b>Regular nitrate therapy</b> (e.g. isosorbide mononitrate)	Eccentric dosing regimen (e.g. twice daily at 8 a.m. and 2 p.m.)	Reduces development of nitrate tolerance by allowing drug-free period each night
<b>Aspirin</b>	With food	Minimises gastrototoxic effects
<b>Alendronate</b>	Once in the morning before breakfast, sitting upright	Minimises risk of oesophageal irritation
<b>Tetracyclines</b>	2 hours before or after food or antacids	Divalent and trivalent cations chelate tetracyclines, preventing absorption
<b>Hypnotics</b> (e.g. temazepam)	Once at night	Maximises therapeutic effect and minimises daytime sedation
<b>Antihypertensive drugs</b> (e.g. amlodipine)	Once in the morning	Blood pressure is higher during the daytime

(HMG CoA = 3-hydroxy-3-methylglutaryl-coenzyme A)

### 2.21 What patients need to know about their medicines\*

Knowledge	Comment
<b>The reason for taking the medicine</b>	Reinforces the goals of therapy
<b>How the medicine works</b>	
<b>How to take the medicine</b>	May be important for the effectiveness (e.g. inhaled salbutamol in asthma) and safety (e.g. alendronate for osteoporosis) of treatment
<b>What benefits to expect</b>	May help to support adherence or prompt review because of treatment failure
<b>What adverse effects might occur</b>	Discuss common and mild effects that may be transient and might not require discontinuation Mention rare but serious effects that might influence the patient's consent
<b>Precautions that improve safety</b>	Explain symptoms to report that might allow serious adverse effects to be averted, monitoring that will be required and potentially important drug–drug interactions
<b>When to return for review</b>	This will be important to enable monitoring

\*Many medicines are provided with patient information leaflets, which the patient should be encouraged to read.

## Prescribing in special circumstances

### Prescribing for patients with renal disease

Patients with renal impairment are identified by a low estimated glomerular filtration rate (eGFR < 60 mL/min/1.73 m<sup>2</sup>), based on their serum creatinine, age, sex and ethnic group (see Box 18.1). This group includes a large proportion of elderly patients. If a drug (or its active metabolites) is eliminated predominantly by the kidneys, it will tend to accumulate and so the maintenance dose must be reduced. For some drugs, renal impairment makes patients more sensitive to their adverse pharmacodynamic effects. Examples of drugs that require extra caution in patients with renal disease are listed in Box 2.22.

### Prescribing for patients with hepatic disease

The liver has a large capacity for drug metabolism and hepatic insufficiency has to be advanced before drug dosages need to be modified. Patients who may have impaired metabolism include those with jaundice, ascites, hypoalbuminaemia, malnutrition or encephalopathy. Hepatic drug clearance may also be reduced in acute hepatitis, in

hepatic congestion due to cardiac failure and in the presence of intra-hepatic arteriovenous shunting (e.g. in hepatic cirrhosis). There are no good tests of hepatic drug-metabolising capacity or of biliary excretion, so dosage should be guided by the therapeutic response and careful monitoring for adverse effects. The presence of liver disease also increases the susceptibility to adverse pharmacological effects of drugs. Some drugs that require extra caution in patients with hepatic disease are listed in Box 2.22.

### Prescribing for older patients

The issues around prescribing in old age are discussed in Box 2.23.

### Prescribing for women who are pregnant or breastfeeding

Prescribing in pregnancy should be avoided if possible to minimise the risk of adverse effects in the fetus. Drug therapy in pregnancy may, however, be required either for a pre-existing problem (e.g. epilepsy, asthma, hypothyroidism) or for problems that arise during pregnancy (e.g. morning sickness, anaemia, prevention of neural tube defects, gestational diabetes, hypertension). About 35% of women take drug

2.22 Some drugs that require extra caution in patients with renal or hepatic disease	
Kidney disease	Liver disease
<b>Pharmacodynamic effects enhanced</b>	
ACE inhibitors and ARBs (renal impairment, hyperkalaemia)	Warfarin (increased anticoagulation because of reduced clotting factor synthesis)
Metformin (lactic acidosis)	Metformin (lactic acidosis)
Spirolactone (hyperkalaemia)	Chloramphenicol (bone marrow suppression)
NSAIDs (impaired renal function)	NSAIDs (gastrointestinal bleeding, fluid retention)
Sulphonylureas (hypoglycaemia)	Sulphonylureas (hypoglycaemia)
Insulin (hypoglycaemia)	Benzodiazepines (coma)
<b>Pharmacokinetic handling altered (reduced clearance)</b>	
Aminoglycosides (e.g. gentamicin)	Phenytoin
Vancomycin	Rifampicin
Other antibiotics (e.g. ciprofloxacin)	Propranolol
Digoxin	Warfarin
Lithium	Diazepam
Atenolol	Lidocaine
Allopurinol	Opioids (e.g. morphine)
Cephalosporins	
Methotrexate	
Opioids (e.g. morphine)	
(ACE = angiotensin-converting enzyme; ARB = angiotensin receptor blocker; NSAID = non-steroidal anti-inflammatory drug)	

therapy at least once during pregnancy and 6% take drug therapy during the first trimester (excluding iron, folic acid and vitamins). The most commonly used drugs are simple analgesics, antibacterial drugs and antacids. Some considerations when prescribing in pregnancy are listed in Box 2.24.

Drugs that are excreted in breast milk may cause adverse effects in the baby. Prescribers should always consult the SPC for each drug or a reliable formulary when treating a pregnant woman or breastfeeding mother.

## Writing prescriptions

A prescription is a means by which a prescriber communicates the intended plan of treatment to the pharmacist who dispenses a medicine and to a nurse or patient who administers it. It should be precise, accurate, clear and legible. The two main kinds of prescription are those written, dispensed and administered in hospital and those written in primary care (in the UK by a GP), dispensed at a community pharmacy and self-administered by the patient. The information supplied must include:

- the date
- the identification details of the patient
- the name of the drug
- the formulation
- the dose
- the frequency of administration
- the route and method of administration
- the amount to be supplied (primary care only)
- instructions for labelling (primary care only)
- the prescriber's signature.

## Prescribing in hospital

Although primary care prescribing is increasingly electronic, many hospital prescriptions continue to be based around the prescription and administration record (the 'drug chart') (Fig. 2.8). A variety of charts are

## 2.23 Prescribing in old age

- **Reduced drug elimination:** partly due to impaired renal function.
- **Increased sensitivity to drug effects:** notably in the brain (leading to sedation or delirium) and as a result of comorbidities.
- **More drug interactions:** largely as a result of polypharmacy.
- **Lower starting doses and slower dose titration:** often required, with careful monitoring of drug effects.
- **Drug adherence:** may be poor because of cognitive impairment, difficulty swallowing (dry mouth) and complex polypharmacy regimens. Supplying medicines in pill organisers (e.g. dosette boxes or calendar blister packs), providing automatic reminders, and regularly reviewing and simplifying the drug regimen can help.
- **Some drugs that require extra caution, and their mechanisms:**
  - Digoxin:* increased sensitivity of Na<sup>+</sup>/K<sup>+</sup> pump; hypokalaemia due to diuretics; renal impairment favours accumulation → increased risk of toxicity.
  - Antihypertensive drugs:* reduced baroreceptor function → increased risk of postural hypotension.
  - Antidepressants, hypnotics, sedatives, tranquillisers:* increased sensitivity of the brain; reduced metabolism → increased risk of toxicity.
  - Warfarin:* increased tendency to falls and injury and to bleeding from intra- and extracranial sites; increased sensitivity to inhibition of clotting factor synthesis → increased risk of bleeding.
  - Amitriptyline, diltiazem, lidocaine, metoprolol, morphine, propranolol, theophylline:* metabolism reduced → increased risk of toxicity.
  - Non-steroidal anti-inflammatory drugs:* poor renal function → increased risk of renal impairment; susceptibility to gastrototoxicity → increased risk of upper gastrointestinal bleeding.

## 2.24 Prescribing in pregnancy

- **Teratogenesis:** a potential risk, especially when drugs are taken between 2 and 8 weeks of gestation (4–10 weeks from last menstrual period). Common teratogens include retinoids (e.g. isotretinoin), cytotoxic drugs, angiotensin-converting enzyme inhibitors, antiepileptics (e.g. sodium valproate) and warfarin. If there is inadvertent exposure, then the timing of conception should be established, counselling given and investigations undertaken for fetal abnormalities.
- **Adverse fetal effects in late gestation:** e.g. tetracyclines may stain growing teeth and bones; sulphonamides displace fetal bilirubin from plasma proteins, potentially causing kernicterus; opioids given during delivery may be associated with respiratory depression in the neonate.
- **Altered maternal pharmacokinetics:** extracellular fluid volume and  $V_d$  increase. Plasma albumin falls but other binding globulins (e.g. for thyroid and steroid hormones) increase. Glomerular filtration increases by approximately 70%, enhancing renal clearance. Placental metabolism contributes to increased clearance, e.g. of levothyroxine and glucocorticoids. The overall effect is a fall in plasma concentration of many drugs.
- **In practice:**
  - Avoid any drugs unless the risk:benefit analysis is in favour of treating (usually the mother).
  - Use drugs for which there is some record of safety in humans.
  - Use the lowest dose for the shortest time possible.
  - Choose the least harmful drug if alternatives are available.

in use and prescribers must familiarise themselves with the local version. Most contain the following sections:

- **Basic patient information:** will usually include name, age, date of birth, hospital number and address. These details are often 'filled in' using a sticky addressograph label, but this increases the risk of serious error.
- **Previous adverse reactions/allergies:** communicates important patient safety information based on a careful drug history and/or the medical record.
- **Other medicines charts:** notes any other hospital prescription documents that contain current prescriptions being received by the patient (e.g. anticoagulants, insulin, oxygen, fluids).
- **Once-only medications:** for prescribing medicines to be used infrequently, such as single-dose prophylactic antibiotics and other pre-operative medications.

- *Regular medications*: for prescribing medicines to be taken for a number of days or continuously, such as a course of antibiotics or antihypertensive drugs.
- *'As required' medications*: for prescribing for symptomatic relief, usually to be administered at the discretion of the nursing staff (e.g. antiemetics, analgesics).

Prescribers should be aware of the risks of prescription error (Box 2.25 and see Box 2.14), ensure they have considered the rational basis for their prescribing decision and then follow the guidance illustrated in Figure 2.8 in order to write the prescription. It is a basic principle that a prescription will be followed by a judgement as to its success or failure and any appropriate changes made (e.g. altered dosage, discontinuation or substitution).

### Hospital discharge ('to take out') medicines

Most patients will be prescribed a short course of their medicines at discharge. This prescription is particularly important because it

usually informs future therapy at the point of transfer of prescribing responsibility to primary care. Great care is required to ensure that this list is accurate. It is particularly important to ensure that any hospital medicines that should be stopped are not included and that those intended to be administered for a short duration only are clearly identified. It is also important for any significant ADRs experienced in hospital to be recorded and any specific monitoring or review identified.

### Prescribing in primary care

Most of the considerations above are equally applicable to primary care (GP) prescriptions. In many health-care systems, community prescribing is electronic, making issues of legibility irrelevant and often providing basic decision support to limit the range of doses that can be written and highlight potential drug interactions. Important additional issues more relevant to GP prescribing are:

**A**

**CODES FOR NON-ADMINISTRATION OF PRESCRIBED MEDICINE**

If a dose is not administered as prescribed, initial and enter a code in the column with a circle drawn round the code according to the reason as shown below. Inform the responsible doctor of the appropriate timescale.

1. Patient refuses	6. Vomiting/nausea
2. Patient not present	7. Time varied on doctor's instructions
3. Medicines not available – CHECK ORDERED	8. Once-only/as-required medicine given
4. Asleep/drowsy	9. Dose withheld on doctor's instructions
5. Administration route not available – CHECK FOR ALTERNATIVE	10. Possible adverse reaction/side-effect

**B**

**ONCE-ONLY MEDICINES**

Date	Time	Medicine (approved name)	Dose	Route	Prescriber – sign and print	Time given	Given by
<i>14. 2. 22</i>	<i>16.00</i>	<i>MORPHINE</i>	<i>5 mg</i>	<i>IV</i>	<i>[Signature] S. JONES</i>	<i>16.20</i>	<i>ST</i>
<i>14. 2. 22</i>	<i>16.00</i>	<i>GLYCERYL TRINITRATE</i>	<i>400 micrograms</i>	<i>SL</i>	<i>[Signature] S. JONES</i>	<i>16.10</i>	<i>DK</i>
<i>14. 2. 22</i>	<i>16.00</i>	<i>METOCLOPRAMIDE</i>	<i>10 mg</i>	<i>IV</i>	<i>[Signature] S. JONES</i>	<i>16.20</i>	<i>ST</i>

**Fig. 2.8** Example of a hospital prescription and administration record ('drug chart'). **A** *Front page*. The correct identification of the patient is critical to reducing the risk of an administration error. This page also clearly identifies other prescriptions charts in use and previous adverse reactions to drugs to minimise the risk of repeated exposure. Note also the codes employed by the nursing staff to indicate reasons why drugs may not have been administered. The patient's name and date of birth should be written on each page of the chart. The patient's weight and height may be required to calculate safe doses for many drugs with narrow therapeutic indices. **B** *'Once-only medicines'*. This area is used for prescribing medicines that are unlikely to be repeated on a regular basis. Note that the prescriber has written the **names of all drugs** legibly in block capitals. The generic international non-proprietary name (INN) should be used in preference to the brand name (e.g. write 'SIMVASTATIN', not 'ZOCOR'). The only exceptions are when variation occurs in the properties of alternative branded formulations (e.g. modified-release preparations of drugs such as lithium, theophylline, phenytoin and nifedipine) or when the drug is a combination product with no generic name (e.g. Klvovance®). The only acceptable abbreviations for **drug dose** units are 'g' and 'mg'. 'Units' (e.g. of insulin or heparin) and 'micrograms' must always be written in full, never as 'U' or 'µg' (nor 'mcg', nor 'ug'). For liquid preparations write the dose in mg; 'mL' can be written only for a combination product (e.g. Gaviscon liquid) or if the strength is not expressed in weight (e.g. adrenaline (epinephrine) 1 in 1000). Use numbers/figures (e.g. 1 or 'one') to denote use of a sachet/enema but avoid prescribing numbers of tablets without specifying their strength. Always include the dose of inhaled drugs in addition to stating numbers of 'puffs', as strengths can vary. Widely accepted abbreviations for **route of administration** are: intravenous – 'IV'; intramuscular – 'IM'; subcutaneous – 'SC'; sublingual – 'SL'; per rectum – 'PR'; per vaginam – 'PV'; nasogastric – 'NG'; inhaled – 'INH'; and topical – 'TOP'. 'ORAL' is preferred to per oram – 'PO'. Care should be taken in specifying 'RIGHT' or 'LEFT' for eye and ear drops. The prescriber should sign and print their name clearly so that they can be identified by colleagues. The prescription should be dated and have an administration time. The nurse who administered the prescription has signed to confirm that the dose has been administered.

**Fig. 2.8, cont'd C** 'Regular medicines'. This area is used for prescribing medicines that are going to be given regularly. In addition to the name, dose and route, a **frequency of administration** is required for each medicine. Widely accepted Latin abbreviations for dose frequency are: once daily – 'OD'; twice daily – 'BD'; 3 times daily – 'TDS'; 4 times daily – 'QDS'; as required – 'PRN'; in the morning – 'OM' (omni mane); at night – 'ON' (omni nocte); and immediately – 'stat'. The hospital chart usually requires specific times to be identified for regular medicines that coincide with nursing drug rounds and these can be circled. If treatment is for a known time period, cross off subsequent days when the medicine is not required. The **'notes'** box can be used to communicate additional important information (e.g. whether a medicine should be taken with food, type of inhaler device used, and anything else that the drug dispenser should know). State here the times for peak/trough plasma levels for drugs requiring therapeutic monitoring. Prescriptions should be **discontinued** by drawing a vertical line at the point of discontinuation, horizontal lines through the remaining days on the chart, and diagonal lines through the drug details and administration boxes. This action should be signed and dated and a supplementary note written to explain it (e.g. describing any adverse effect). In this example, amlodipine has been discontinued because of ankle oedema. There is room for the ward pharmacist to sign to indicate that the prescription has been reviewed and that a supply of the medicine is available. The administration boxes allow the nurse to sign to confirm that the dose has been given. Note that these boxes also allow for recording of reasons for non-administration (in this example '2' indicates that the patient was not present on the ward at the time) and the prevention of future administration by placing an 'X' in the box. **D** 'As-required medicines'. These prescriptions leave the administration of the drug to the discretion of the nursing staff. The prescription must describe clearly the indication, frequency, minimal time interval between doses, and maximum dose in any 24-hour period (in this case, the maximum daily dose of paracetamol is 4g).

- **Formulation.** The prescription needs to carry information about the formulation for the dispensing pharmacist (e.g. tablets or oral suspension).
- **Amount to be supplied.** A pharmacist will organise this in hospital. Elsewhere it must be specified either as the precise number of tablets or as the duration of treatment. Creams and ointments should be specified in grams and lotions in mL.
- **Controlled drugs.** Prescriptions for 'controlled' drugs (e.g. opioid analgesics, with potential for drug abuse) are subject to additional

- legal requirements. In the UK, they must contain the address of the patient and prescriber (not necessary on most hospital forms), the form and the strength of the preparation, and the total quantity of the preparation/number of dose units in both words and figures.
- **'Repeat prescriptions'**. A large proportion of GP prescribing involves 'repeat prescriptions' for chronic medication. These are often generated automatically, although the prescriber remains responsible for regular review and for ensuring that the benefit-to-harm ratio remains favourable.

## Monitoring drug therapy

Prescribers should measure the effects of the drug, both beneficial and harmful, to inform decisions about dose titration (up or down), discontinuation or substitution of treatment. Monitoring can be achieved subjectively by asking the patient about symptoms or, more objectively, by measuring a clinical effect, which may be possible to assess by clinical examination (e.g. eczematous rash), physiological measurement (e.g. blood pressure, pulse oximetry), imaging (e.g. chest X-ray, CT scan) or laboratory tests (e.g. haemoglobin, INR (International Normalised Ratio)). Alternatively, if the pharmacodynamic effects of the drug are difficult to assess, the plasma drug concentration may be measured, if this is closely related to the effect of the drug (see Fig. 2.2). Rational prescribing ultimately rests on continuous monitoring of the balance between the risks and benefits of drug therapy. Common examples are ACE inhibitors (negative impact on renal function versus blood pressure-lowering), cancer chemotherapy (bone marrow suppression versus radiological tumour regression) and disease-modifying anti-rheumatic drugs (liver toxicity versus anti-inflammatory effect). Advances in therapeutics have also led to increasing complexity of ongoing monitoring

requirements. The recognition that hospital specialist clinics cannot take on the responsibility for monitoring of all chronic disease therapy has led to the development of 'shared care protocols' that aim to share monitoring activities between specialists and primary care physicians with the aim of maximising efficient use of health-care resources and convenience for patients.

## Clinical and surrogate endpoints

Ideally, clinical endpoints are measured directly and the drug dosage titrated to achieve the therapeutic goal and avoid toxicity (e.g. control of ventricular rate in a patient with atrial fibrillation, monitoring anticoagulation using INR). Sometimes this is impractical because the clinical endpoint is a future event (e.g. prevention of myocardial infarction by statins or resolution of a chest infection with antibiotics); in these circumstances, it may be possible to select a 'surrogate' endpoint that will predict success or failure. This may be an intermediate step in the pathophysiological process (e.g. serum cholesterol as a surrogate for risk of myocardial infarction) or a measurement that follows the pathophysiology, even if it is not a key factor in its progression (e.g. serum C-reactive protein as a surrogate for resolution of inflammation in chest infection, TSH as a surrogate for adequate replacement of levothyroxine). Such surrogates are sometimes termed 'biomarkers'.

### i

#### 2.25 High-risk prescribing moments

- Trying to amend an active prescription (e.g. altering the dose/timing) – *always avoid and start again*
- Writing up drugs in the immediate presence of more than one prescription chart or set of notes – *avoid*
- Allowing one's attention to be diverted in the middle of completing a prescription – *avoid*
- Prescribing 'high-risk' drugs (e.g. anticoagulants, opioids, insulin, sedatives) – *ask for help if necessary*
- Prescribing parenteral drugs – *take care*
- Rushing prescribing (e.g. in the midst of a busy ward round) – *avoid*
- Prescribing unfamiliar drugs – *consult the formulary and ask for help if necessary*
- Transcribing multiple prescriptions from an expired chart to a new one – *take care to review the rationale for each medicine*
- Writing prescriptions based on information from another source such as a referral letter (the list may contain errors and some of the medicines may be the cause of the patient's illness) – *review the justification for each as if it is a new prescription*
- Writing up 'to take out' drugs (because these will become the patient's regular medication for the immediate future) – *take care and seek advice if necessary*
- Calculating drug doses – *ask a colleague to perform an independent calculation or use approved electronic dose calculators*
- Prescribing sound-alike or look-alike drugs (e.g. chlorphenamine and chlorpromazine) – *take care*

## Plasma drug concentration

The following criteria must be met to justify routine monitoring by plasma drug concentration:

- Clinical endpoints and other pharmacodynamic (surrogate) effects are difficult to monitor.
- The relationship between plasma concentration and clinical effects is predictable.
- The therapeutic index is low. For drugs with a high therapeutic index, any variability in plasma concentrations is likely to be irrelevant clinically.

Some examples of drugs that fulfil these criteria are listed in Box 2.26.

Measurement of plasma concentration may be useful in planning adjustments of drug dose and frequency of administration; to explain an inadequate therapeutic response (by identifying subtherapeutic concentration or incomplete adherence); to establish whether a suspected ADR is likely to be caused by the drug; and to assess and avoid potential drug interactions.

### Timing of samples in relation to doses

The concentration of drug rises and falls during the dosage interval (see Fig. 2.4B). Measurements made during the initial absorption and

### i

#### 2.26 Drugs commonly monitored by plasma drug concentration

Drug	Half-life (hrs)*	Comment
Digoxin	36	Steady state takes several days to achieve. Samples should be taken 6 hrs post dose. Measurement is useful to confirm the clinical impression of toxicity or non-adherence but clinical effectiveness is better assessed by ventricular heart rate. Risk of toxicity increases progressively at concentrations > 1.5 µg/L, and is likely at concentrations > 3.0 µg/L (toxicity is more likely in the presence of hypokalaemia)
Gentamicin	2	Measure pre-dose trough concentration (should be < 1 mg/L) to ensure that accumulation (and the risk of nephrotoxicity and ototoxicity) is avoided; see Fig. 6.18
Lithium	24	Steady state takes several days to achieve. Samples should be taken 12 hrs post dose. Target range 0.4–1 mmol/L
Phenytoin	24	Measure pre-dose trough concentration (should be 10–20 mg/L) to ensure that accumulation is avoided. Good correlation between concentration and toxicity. Concentration may be misleading in the presence of hypoalbuminaemia
Theophylline (oral)	6	Steady state takes 2–3 days to achieve. Samples should be taken 6 hrs post dose. Target concentration is 10–20 mg/L but its relationship with bronchodilator effect and adverse effects is variable
Vancomycin	6	Measure pre-dose trough concentration (should be 10–15 mg/L) to ensure clinical efficacy and that accumulation and the risk of nephrotoxicity are avoided

\*Half-lives vary considerably with different formulations and between patients.

distribution phases are unpredictable because of the rapidly changing concentration, so samples are usually taken at the end of the dosage interval (a 'trough' or 'pre-dose' concentration). This measurement is normally made in steady state, which usually takes 5 half-lives to achieve after the drug is introduced or the dose changed (unless a loading dose has been given).

### **Interpreting the result**

A target range is provided for many drugs, based on average thresholds for therapeutic benefit and toxicity. Inter-individual variability means that these can be used only as a guide. For instance, in a patient who describes symptoms that could be consistent with toxicity, but has a drug concentration in the top half of the target range, toxic effects should still be suspected. Another important consideration is that some drugs are heavily protein-bound (e.g. phenytoin), but only the unbound drug is pharmacologically active. Patients with hypoalbuminaemia may, therefore, have a therapeutic or even toxic concentration of unbound drug, despite a low 'total' concentration.

## Multiple Choice Questions

2.1. Which of the following drugs for type 2 diabetes acts on a transporter protein?

- A. Gliclazide
- B. Dapagliflozin
- C. Metformin hydrochloride
- D. Pioglitazone
- E. Sitagliptin

Answer: B.

Dapagliflozin is a sodium-glucose co-transporter 2 inhibitor that is indicated for the treatment of type 2 diabetes mellitus. Dapagliflozin improves glycaemic control by inhibiting glucose re-absorption in the proximal tubule of the nephron leading to excretion of excess glucose in the urine (glycosuria).

2.2. Which of the following is a prodrug that depends on hepatic metabolism for conversion to its active form?

- A. Amlodipine
- B. Clopidogrel
- C. Metoprolol
- D. Simvastatin
- E. Tramadol

Answer: B.

Clopidogrel binds specifically and irreversibly to the platelet P2RY12 purinergic receptor to inhibit ADP-mediated platelet activation and aggregation. Clopidogrel is a prodrug that is absorbed in the intestine and activated in the liver. The conversion of clopidogrel to its active metabolite involves two sequential oxidation reactions that involve various cytochrome P450 isoforms (CYP1A2, CYP2B6, CYP2C9, CYP2C19 and CYP3A4/5).

2.3. A 52-year-old man who is being treated with azathioprine 150mg orally daily to maintain remission from Crohn's disease presents to hospital with severe pancytopenia. Which of his other current medicines (listed below) is most likely to have interacted with azathioprine to cause this adverse drug reaction?

- A. Allopurinol 200mg orally daily
- B. Atorvastatin 20mg orally daily
- C. Indapamide 2.5mg orally daily
- D. Metronidazole 400mg orally three times daily
- E. Omeprazole 20mg orally daily

Answer: A.

Allopurinol inhibits the enzyme xanthine oxidase (XO), which is one of the three enzymes responsible for inactivating 6-mercaptopurine, its active purine metabolite. Normally, XO is needed to convert the purine base hypoxanthine to xanthine and then xanthine to uric acid. Allopurinol is a structural analogue of hypoxanthine and binds to XO, thereby inhibiting its effect on purine metabolism.

2.4. Which of the following regular medicines is most likely to require a dose reduction in a patient who develops chronic renal impairment (chronic kidney disease stage 3)?

- A. Bendroflumethiazide 2.5mg orally daily
- B. Digoxin 125micrograms orally daily
- C. Fluoxetine 20mg orally daily
- D. Simvastatin 20mg orally nightly
- E. Verapamil hydrochloride m/r 120mg orally daily

Answer: B.

Digoxin is mainly eliminated by renal excretion and there is a risk of toxicity if the dosage is not reduced as renal function deteriorates. Bendroflumethiazide becomes less effective as renal function deteriorates but does not require a dose reduction (unless there is evidence that dehydration is a contributory factor). Simvastatin should be used with caution if the eGFR falls below 30mL/min/1.73m<sup>2</sup>. Verapamil is eliminated by hepatic metabolism. Fluoxetine does not require dose adjustment.

2.5. Which of the following aspects of a new drug is not considered by drug regulators but considered by health-care providers (e.g. a hospital drug and therapeutics committee)?

- A. Manufacturing standards
- B. Safety profile
- C. Efficacy in treating the clinical indication
- D. Cost-effectiveness
- E. Patient information

Answer: D.

The role of national drug regulatory authorities is to ensure that any new medicine meets minimum acceptable standards of quality, safety and efficacy prior to being granted a market authorisation. It is not the role of the regulator to assess cost-effectiveness which is devolved to national or local health technology assessments that may compare the new drug with other available treatment options.

Genomics and health care 52  
Genomics in infectious disease 55  
Treatment of genetic disease 56  
Ethics in a genomic age 56

We have entered a genomic era. Powerful new technologies are driving forward transformational change in health care. Genetic sequencing has evolved from the targeted sequencing of a single gene to the parallel sequencing of multiple genes. In addition to improving the chances of identifying a genetic cause of rare diseases, these technologies are increasingly directing therapies and, in the future, are likely to be used in the diagnosis and prevention of common diseases such as diabetes. In this chapter we explore the fundamentals of genomics, the basic principles underlying these new genomic technologies and how the data generated can be applied safely for patient benefit. We will review the use of genomic technology across a breadth of medical specialties, including obstetrics, paediatrics, oncology and infectious disease, and consider how health care is being transformed by these new genomic technologies. Finally, we will consider the ethical impact that these technologies are likely to have, both for the individual and for their wider family.

## The fundamental principles of genomics

### The packaging of genes: DNA, chromatin and chromosomes

Genes are functional units encoded in double-stranded deoxyribonucleic acid (DNA), packaged as chromosomes and located in the nucleus of the cell: a membrane-bound compartment found in all cells except erythrocytes and platelets (Fig. 3.1). DNA consists of a linear sequence of just four

**Fig. 3.1** The packaging of DNA, genes and chromosomes. From bottom to top: the double helix and the complementary DNA bases; chromatin; and a normal female chromosome pattern – the karyotype.

bases: adenine (A), cytosine (C), thymine (T) and guanine (G.) It forms a ‘double helix’, a twisted ladder-like structure formed from two complementary strands of DNA joined by hydrogen bonds between bases on the opposite strand that can form only between a C and a G base and an A and a T base. It is this feature of DNA that enables faithful DNA replication and is the basis for many of the technologies designed to interrogate the genome: when the DNA double helix ‘unzips’, one strand can act as a template for the creation of an identical strand.

A single copy of the human genome comprises approximately 3.1 billion base pairs of DNA, wound around proteins called histones. The unit consisting of 147 base pairs wrapped around four different histone proteins is called the nucleosome. Sequences of nucleosomes (resembling a string of beads) are wound and packaged to form chromatin: tightly wound, densely packed chromatin is called heterochromatin and open, less tightly wound chromatin is called euchromatin.

The chromatin is finally packaged into the chromosomes. Humans are diploid organisms: the nucleus contains two copies of the genome, visible microscopically as 23 chromosome pairs (known as the karyotype). Chromosomes 1 through to 22 are known as the autosomes and consist of identical chromosome pairs. The 23rd ‘pair’ of chromosomes are the two sex chromosomes: females have two X chromosomes and males an X and Y chromosome. A normal female karyotype is therefore written as 46,XX and a normal male is 46,XY.

## From DNA to protein

Genes are functional elements on the chromosome that are capable of transmitting information from the DNA template via the production of messenger ribonucleic acid (mRNA) to the production of proteins. The human genome contains over 20000 genes, although many of these are inactive or silenced in different cell types, reflecting the variable gene expression responsible for cell-specific characteristics. The central dogma is the pathway describing the basic steps of protein production: transcription, splicing, translation and protein modification (Fig. 3.2). Although this is now recognised as an over-simplification (contrary to this linear relationship, a single gene will often encode many different proteins), it remains a useful starting point to explore protein production.

### Transcription: DNA to messenger RNA

Transcription describes the production of ribonucleic acid (RNA) from the DNA template. For transcription to commence, an enzyme called RNA polymerase binds to a segment of DNA at the start of the gene: the promoter. Once bound, RNA polymerase moves along one strand of DNA, producing an RNA molecule complementary to the DNA template. In protein-coding genes this is known as messenger RNA (mRNA). A DNA sequence close to the end of the gene, called the polyadenylation signal, acts as a signal for termination of the RNA transcript (Fig. 3.3).

**Fig. 3.2** The central dogma of protein production. Double-stranded DNA as a template for single-stranded RNA, which codes for the production of a peptide chain of amino acids. Each of these chains has an orientation. For DNA and RNA, this is 5' to 3'. For peptides, this is N-terminus to C-terminus.

**Fig. 3.3** RNA synthesis and its translation into protein. Gene transcription involves binding of RNA polymerase II to the promoter of genes being transcribed with other proteins (transcription factors) that regulate the transcription rate. The primary RNA transcript is a copy of the whole gene and includes both introns and exons, but the introns are removed within the nucleus by splicing and the exons are joined to form the messenger RNA (mRNA). Prior to export from the nucleus, a methylated guanosine nucleotide is added to the 5' end of the RNA ('cap') and a string of adenine nucleotides is added to the 3' ('polyA tail'). This protects the RNA from degradation and facilitates transport into the cytoplasm. In the cytoplasm, the mRNA binds to ribosomes and forms a template for protein production. (tRNA = transfer RNA; UTR = untranslated region)

RNA differs from DNA in three main ways:

- RNA is single-stranded.
- The sugar residue within the nucleotide is ribose, rather than deoxyribose.
- It contains uracil (U) in place of thymine (T).

The activity of RNA polymerase is regulated by transcription factors. These proteins bind to specific DNA sequences at the promoter or to enhancer elements that may be many thousands of base pairs away from the promoter; a loop in the chromosomal DNA brings the enhancer close to the promoter, enabling the bound proteins to interact. The human genome encodes more than 1200 different transcription factors. Mutations (now more frequently referred to as gene variants) within transcription factors, promoters and enhancers can cause disease. For example, the blood disorder alpha-thalassaemia is usually caused by gene deletions (see Box 3.4). However, it can also result from a variant in an enhancer located more than 100 000 base pairs (bp) from the  $\alpha$ -globin gene promoter, leading to greatly reduced transcription.

Gene activity, or expression, is influenced by a number of complex interacting factors, including the accessibility of the gene promoter to transcription factors. DNA can be modified by the addition of a methyl group to cytosine molecules (methylation). If DNA methylation occurs in promoter regions, transcription is silenced, as methyl cytosines are usually not available for transcription factor binding. A second mechanism determining promoter accessibility is the structural configuration of chromatin. In open chromatin, called euchromatin, gene promoters are accessible to RNA polymerase and transcription factors; therefore it is transcriptionally active. This contrasts with heterochromatin, which is densely packed and transcriptionally silent. The chromatin configuration is determined by modifications (such as methylation or acetylation) of specific amino acid residues of histone protein tails.

Modifications of DNA and histone protein tails are termed epigenetic ('epi-' meaning 'above' the genome), as they do not alter the primary sequence of the DNA code but have biological significance in chromosomal function. Abnormal epigenetic changes are increasingly recognised as important events in the progression of cancer, allowing expression of normally silenced genes that result in cancer cell de-differentiation and proliferation. They also afford therapeutic targets. For instance, the histone deacetylase inhibitor vorinostat has been successfully used to treat cutaneous T-cell lymphoma, due to the re-expression of genes that had previously been silenced in the tumour. These genes encode transcription factors that promote T-cell differentiation as opposed to proliferation, thereby causing tumour regression.

### RNA splicing, editing and degradation

Transcription produces an RNA molecule that is a copy of the whole gene, termed the primary or nascent transcript. This nascent transcript then undergoes splicing, whereby regions not required to make protein (the intronic regions) are removed while those segments that are necessary for protein production (the exonic regions) are retained and rejoined.

Splicing is a highly regulated process that is carried out by a multimeric protein complex called the spliceosome. Following splicing, the mRNA molecule is exported from the nucleus and used as a template for protein synthesis. Many genes produce more than one form of mRNA (and thus protein) by a process termed alternative splicing, in which different combinations of exons are joined together. Different proteins from the same gene can have entirely distinct functions. For example, in thyroid C cells the calcitonin gene produces mRNA encoding the osteoclast inhibitor calcitonin, but in neurons the same gene produces an mRNA with a different complement of exons via alternative splicing that encodes a neurotransmitter, calcitonin-gene-related peptide.

## Translation and protein production

Following splicing, the segment of mRNA containing the code that directs synthesis of a protein product is called the open reading frame (ORF). The inclusion of a particular amino acid in the protein is specified by a codon composed of three contiguous bases. There are 64 different codons with some redundancy in the system: 61 codons encode one of the 20 amino acids, and the remaining three codons – UAA, UAG and UGA (known as stop codons) – cause termination of the growing polypeptide chain. ORFs in humans most commonly start with the amino acid methionine. All mRNA molecules have domains before and after the ORF called the 5' untranslated region (UTR) and 3'UTR, respectively. The start of the 5'UTR contains a cap structure that protects mRNA from enzymatic degradation, and other elements within the 5'UTR are required for efficient translation. The 3'UTR also contains elements that regulate efficiency of translation and mRNA stability, including a stretch of adenine bases known as a polyA tail (see Fig. 3.3).

The mRNAs then leave the nucleus via nuclear pores and associate with ribosomes, the sites of protein production (see Fig. 3.3). Each ribosome consists of two subunits (40S and 60S), which comprise non-coding rRNA molecules (see Fig. 3.9) complexed with proteins. During translation, a different RNA molecule known as transfer RNA (tRNA) binds to the ribosome. The tRNAs deliver amino acids to the ribosome so that the newly synthesised protein can be assembled in a stepwise fashion. Individual tRNA molecules bind a specific amino acid and 'read' the mRNA ORF via an 'anticodon' of three nucleotides that is complementary to the codon in mRNA (see Fig. 3.3). A proportion of ribosomes is bound to the membrane of the endoplasmic reticulum (ER), a complex tubular structure that surrounds the nucleus.

Proteins synthesised on these ribosomes are translocated into the lumen of the ER, where they undergo folding and processing. From here, the protein may be transferred to the Golgi apparatus, where it undergoes post-translational modifications, such as glycosylation (covalent attachment of sugar moieties), to form the mature protein that can be exported into the cytoplasm or packaged into vesicles for secretion. The clinical importance of post-translational modification of proteins is shown by the severe developmental, neurological, haemostatic and soft tissue abnormalities that are associated with the many different congenital disorders of glycosylation. Post-translational modifications can also be disrupted by the synthesis of proteins with abnormal amino acid sequences. For example, the most common *CFTR* gene variant that causes cystic fibrosis ( $\Delta F508$ ) results in an abnormal protein that cannot be exported from the ER and Golgi (see Box 3.4).

## Non-coding RNA

Approximately 4500 genes in humans encode non-coding RNAs (ncRNA) rather than proteins. There are various categories of ncRNA, including transfer RNA (tRNA), ribosomal RNA (rRNA), ribozymes and microRNA (miRNA). The miRNAs, which number over 1000, have a role in post-translational gene expression: they bind to mRNAs, typically in the 3'UTR, promoting target mRNA degradation and gene silencing. Together, miRNAs affect over half of all human genes and have important roles in normal development, cancer and common degenerative disorders. This is the subject of considerable research interest at present.

## Cell division, differentiation and migration

In normal tissues, molecules such as hormones, growth factors and cytokines provide the signal to activate the cell cycle: a controlled programme of biochemical events that culminates in cell division. In all cells of the body, except the gametes (the sperm and egg cells, also known as the germ line), mitosis completes cell division, resulting in two diploid daughter cells. In contrast, the sperm and eggs cells complete cell division with meiosis, resulting in four haploid daughter cells (Fig. 3.4).

**Fig. 3.4 Meiosis and gametogenesis: the main chromosomal stages of meiosis in both males and females.** A single homologous pair of chromosomes is represented in different colours. The final step is the production of haploid germ cells. Each round of meiosis in the male results in four sperm cells; in the female, however, only one egg cell is produced, as the other divisions are sequestered on the periphery of the mature egg as peripheral polar bodies.

The stages of cell division in the non-germ-line, somatic cells are shown below:

- Cells not committed to mitosis are said to be in  $G_0$ .
- Cells committed to mitosis must go through the preparatory phase of interphase consisting of  $G_1$ , S and  $G_2$ :
  - $G_1$  (first gap): synthesis of the cellular components necessary to complete cell division
  - S (synthesis): DNA replication producing identical copies of each chromosome called the sister chromatids

- $G_2$  (second gap): repair of any errors in the replicated DNA before proceeding to mitosis.
- **Mitosis (M)** consists of four phases:
  - Prophase: the chromosomes condense and become visible, the centrioles move to opposite ends of the cell and the nuclear membrane disappears.
  - Metaphase: the centrioles complete their migration to opposite ends of the cell and the chromosomes – consisting of two identical sister chromatids – line up at the equator of the cell.
  - Anaphase: spindle fibres attach to the chromosome and pull the sister chromatids apart.
  - Telophase: the chromosomes decondense, the nuclear membrane reforms and two daughter cells – each with 46 chromosomes – are formed.

The progression from one phase to the next is tightly controlled by cell-cycle checkpoints. For example, the checkpoint between  $G_2$  and mitosis ensures that all damaged DNA is repaired prior to segregation of the chromosomes. Failure of these control processes is a crucial driver in the pathogenesis of cancer, as discussed on page 130.

- **Meiosis** is a special, gamete-specific, form of cell division (see Fig. 3.4). Like mitosis, meiosis consists of four phases (prophase, metaphase, anaphase and telophase) but differs from mitosis in the following ways:
  - It consists of two separate cell divisions known as meiosis I and meiosis II.
  - It reduces the chromosome number from the diploid to the haploid number via a tetraploid stage, i.e. from 46 to 92 (MI S) to 46 (MI M) to 23 (MII M) chromosomes, so that when a sperm cell fertilises the egg, the resulting zygote will return to a diploid, 46, chromosome complement. This reduction to the haploid number occurs at the end of meiosis II.
  - The 92 chromosome stage consists of 23 homologous pairs of sister chromatids, which then swap genetic material, a process known as recombination. This occurs at the end of MI prophase and ensures that the chromosome that a parent passes to his or her offspring is a mix of the chromosomes that the parent inherited from his or her own mother and father.

The individual steps in meiotic cell division are similar in males and females. However, the timing of the cell divisions is very different. In females, meiosis begins in fetal life but does not complete until after ovulation. A single meiotic cell division can thus take more than 40 years to complete. As women become older, the separation of chromosomes at meiosis II becomes less efficient. That is why the risk of trisomies (p. 42) due to non-disjunction grows greater with increasing maternal age. In males, meiotic division does not begin until puberty and continues throughout life. In the testes, both meiotic divisions are completed in a matter of days.

## Cell death, apoptosis and senescence

With the exception of stem cells, human cells have only a limited capacity for cell division. The Hayflick limit is the number of divisions a cell population can go through in culture before division stops and enters a state known as senescence. This ‘biological clock’ is of great interest in the study of the normal ageing process. Rare human diseases associated with premature ageing, called progeric syndromes, have been very helpful in identifying the importance of DNA repair mechanisms in senescence. For example, in Werner syndrome, a DNA helicase (an enzyme that separates the two DNA strands) is mutated, leading to failure of DNA repair and premature ageing. A distinct mechanism of cell death is seen in apoptosis, or programmed cell death.

Apoptosis is an active process that occurs in normal tissues and plays an important role in development, tissue remodelling and the immune response. The signal that triggers apoptosis is specific to each

tissue or cell type. This signal activates enzymes, called caspases, which actively destroy cellular components, including chromosomal DNA. This degradation results in cell death, but the cellular corpse contains characteristic vesicles called apoptotic bodies. The corpse is then recognised and removed by phagocytic cells of the immune system, such as macrophages, in a manner that does not provoke an inflammatory response.

A third mechanism of cell death is necrosis. This is a pathological process in which the cellular environment loses one or more of the components necessary for cell viability. Hypoxia is probably the most common cause of necrosis.

## Genomics, health and disease

### Classes of genetic variant

There are many different classes of variation in the human genome, categorised by the size of the DNA segment involved and/or by the mechanism giving rise to the variation.

#### Nucleotide substitutions

The substitution of one nucleotide for another is the most common type of genomic variation. This is caused by misincorporation of a nucleotide during DNA synthesis or by chemical modification of the base. When these substitutions occur within ORFs of a protein-coding gene, they are further classified into:

- *synonymous* – resulting in a change in the codon without altering the amino acid
- *non-synonymous* (also known as a missense variant) – resulting in a change in the codon and the encoded amino acid
- *stop gain* (or *nonsense variant*) – introducing a premature stop codon and resulting in truncation of the protein
- *splicing* – disruption of normal splicing and therefore most frequently occurring at the junctions between an intron and an exon.

These different types of gene variants are illustrated in Box 3.1 and examples are shown in Figs. 3.5 and 3.6.

#### Insertions and deletions

One or more nucleotides may be inserted or lost in a DNA sequence, resulting in an insertion/deletion (indel) variant (see Box 3.1 and Fig. 3.5). If a multiple of three nucleotides is involved, this is in-frame. If an indel change affects one or two nucleotides within the ORF of a protein-coding gene, this can have serious consequences because the triple nucleotide sequence of the codons is disrupted, resulting in a frameshift variant. The effect on the gene is typically severe because the amino acid sequence is totally disrupted.

#### Simple tandem repeat variants

Variations in the length of simple tandem repeats of DNA are thought to arise as the result of slippage of DNA during meiosis and are termed microsatellite (small) or minisatellite (larger) repeats. These repeats are unstable and can expand or contract in different generations. This instability is proportional to the size of the original repeat, in that longer repeats tend to be more unstable. Many microsatellites and minisatellites occur in introns or in chromosomal regions between genes and have no obvious adverse effects. However, some genetic diseases are caused by microsatellite repeats that result in duplication of amino acids within the affected gene product or affect gene expression (Box 3.2).

### 3.1 Classes of genetic variant

The classes of genetic variant can be illustrated using the sentence  
'THE FAT FOX WAS ILL COS SHE ATE THE OLD CAT'

#### Synonymous

Silent polymorphism with no amino acid change      THE FAT FOX WAS ILL COS SHE ATE THE OLD **K**AT  
where the C is replaced with a K but the meaning remains the same

#### Non-synonymous

Causing an amino acid change      THE FAT **B**OX WAS ILL COS SHE ATE THE OLD CAT  
where the F of FOX is replaced by B and the original meaning of the sentence is lost

#### Stop-gain (also called a nonsense variant)

Causing the generation of a premature stop codon      THE **C**AT  
where the F of FAT is replaced by a C, generating a premature stop codon

#### Indel

Where the bases are either inserted or deleted; disruption of the reading frame is dependent on the number of bases inserted or deleted

THE FAT FOX WAS ILL ILL COS SHE ATE THE OLD CAT  
where the insertion of three bases results in maintenance of the reading frame

THE FAT FOX WAW ASI LLC OSS HEA TET HEO LDC AT  
where the insertion of two bases results in disruption of the reading frame

### Copy number variations

Variation in the number of copies of an individual segment of the genome from the usual diploid (two copies) content can be categorised by the size of the segment involved. Rarely, individuals may gain (trisomy) or lose (monosomy) a whole chromosome. Such numerical chromosome anomalies most commonly occur by a process known as non-disjunction, where pairs of homologous chromosomes do not separate at meiosis II (p. 40). Common trisomies include Down syndrome (trisomy 21), Edwards syndrome (trisomy 18) and Patau syndrome (trisomy 13). Monosomy of the autosomes (present in all the cells, as opposed to in a

mosaic distribution) does not occur, but Turner syndrome, in which there is monosomy for the X chromosome, affects approximately 1 in 2500 live births (Box 3.3).

Large insertions or deletions of chromosomal DNA also occur and are usually associated with a learning disability and/or congenital malformations. Such structural chromosomal anomalies usually arise as the result of one of two different processes:

- non-homologous end-joining
- non-allelic homologous recombination.

Random double-stranded breaks in DNA are a necessary process in meiotic recombination and also occur during mitosis at a predictable rate. The rate of these breaks is dramatically increased by exposure to ionising radiation. When such breaks take place, they are usually repaired accurately by DNA repair mechanisms within the cell. However, in a proportion of breaks, segments of DNA that are not normally contiguous will be joined ('non-homologous end-joining'). If the joined fragments are from different chromosomes, this results in a translocation. If they are from the same chromosome, this will result in either inversion, duplication or deletion of a chromosomal fragment (Fig. 3.7). Large insertions and deletions may be cytogenetically visible as chromosomal deletions or duplications. If the anomalies are too small to be detected by microscopy, they are termed microdeletions and microduplications. Many microdeletion syndromes have been described and most result from non-allelic homologous recombination between repeats of highly similar DNA sequences, which leads to recurrent chromosome anomalies – and clinical syndromes – occurring in unrelated individuals (see Fig. 3.7 and Box 3.3).

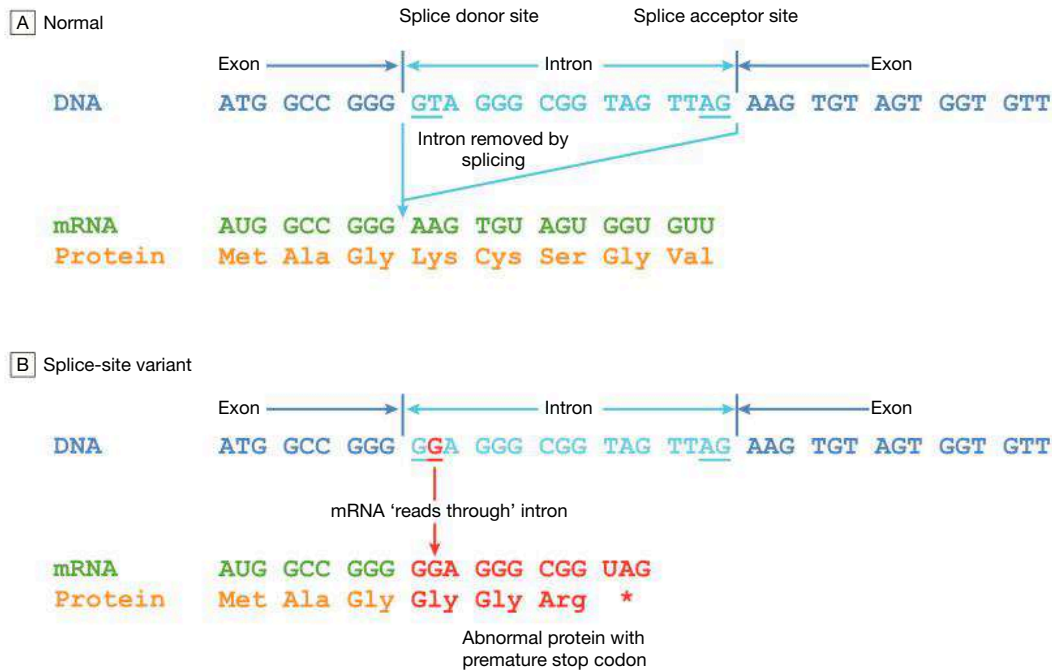

### Consequences of genomic variation

The consequence of an individual genomic variant depends on many factors, including the variant type, the nature of the gene product and the position of the variant in the protein. Variants can have profound or subtle effects on gene and cell function. Variations that have profound effects are responsible for 'classical' genetic diseases, whereas those with subtle effects may contribute to the pathogenesis of common disease where there is a genetic component, such as diabetes.

- *Neutral variants* have no effect on quality or type of protein produced.

A	DNA	ATG GCC GGG AAG TGT CGT GGT GTT	Normal
	mRNA	AUG GCC GGG AAG UGU CGU GGU GUU

**Fig. 3.5** Different types of mutation affecting coding exons. **A** Normal sequence. **B** A synonymous nucleotide substitution changing the third base of a codon; the resulting amino acid sequence is unchanged. **C** A missense variant in which the nucleotide substitution results in a change in a single amino acid from the normal sequence (AAG) encoding lysine to glutamine (CAG). **D** Insertion of a G residue (boxed) causes a frameshift variant, completely altering the amino acid sequence downstream. This usually results in a loss-of-function variant. **E** A nonsense variant resulting in a single nucleotide change from a lysine codon (AAG) to a premature stop codon (TAG).

**Fig. 3.6 Splice-site variants.** **A** The normal sequence is shown, illustrating two exons, and intervening intron (blue) with splice donor (AG) and splice acceptor sites (GT) underlined. Normally, the intron is removed by splicing to give the mature messenger RNA that encodes the protein. **B** In a splice-site variant the donor site is mutated. As a result, splicing no longer occurs, leading to read-through of the mRNA into the intron, which contains a premature termination codon downstream of the variant.

### 3.2 Diseases associated with triplet and other repeat expansions\*

	Repeat	No. of repeats		Gene	Gene location	Inheritance
		Normal	Mutant			
<b>Coding repeat expansion</b>						
Huntington's disease	[CAG]	6–34	> 35	<i>Huntingtin</i>	4p16	AD
Spinocerebellar ataxia (type 1)	[CAG]	6–39	> 40	<i>Ataxin</i>	6p22–23	AD
Spinocerebellar ataxia (types 2, 3, 6, 7)	[CAG]	Various	Various	Various	Various	AD
Dentatorubral-pallidoluysian atrophy	[CAG]	7–25	> 49	<i>Atrophin</i>	12p12–13	AD
Machado–Joseph disease	[CAG]	12–40	> 67	<i>MJD</i>	14q32	AD
Spinobulbar muscular atrophy	[CAG]	11–34	> 40	Androgen receptor	Xq11–12	XL recessive
<b>Non-coding repeat expansion</b>						
Myotonic dystrophy	[CTG]	5–37	> 50	<i>DMPK-3' UTR</i>	19q13	AD
Friedreich's ataxia	[GAA]	7–22	> 200	<i>Frataxin-intronic</i>	9q13	AR
Progressive myoclonic epilepsy	[CCCCGCCCGCG] <sub>4–8</sub>	2–3	> 25	<i>Cystatin B-5' UTR</i>	21q	AR
Fragile X mental retardation	[CGG]	5–52	> 200	<i>FMR1-5' UTR</i>	Xq27	XL dominant
Fragile site mental retardation 2 (FRAXE)	[GCC]	6–35	> 200	<i>FMR2</i>	Xq28	XL, probably recessive
*The triplet repeat diseases fall into two major groups: those with disease stemming from expansion of [CAG] <sub>n</sub> repeats in coding DNA, resulting in multiple adjacent glutamine residues (polyglutamine tracts), and those with non-coding repeats. The latter tend to be longer. Unaffected parents usually display 'pre-mutation' allele lengths that are just above the normal range. (AD/AR = autosomal dominant/recessive; UTR = untranslated region; XL = X-linked)						

- *Loss-of-function variants* result in loss or reduction in the normal protein function. Whole-gene deletions are the archetypal loss-of-function variants but stop-gain or indel variants (early in the ORF), missense variants affecting a critical domain and splice-site variants can also result in loss of protein function.
- *Gain-of-function variants* result in a gain of protein function. They are typically non-synonymous variants that alter the protein structure, leading to activation/alteration of its normal function through causing

either an interaction with a novel substrate or a change in its normal function.

- *Dominant negative variants* are the result of non-synonymous substitutions or in-frame deletions/duplications but may also, less frequently, be caused by triplet repeat expansions. Dominant negative variants are heterozygous changes that result in the production of an abnormal protein that interferes with the normal functioning of the wild-type protein.

3.3 Chromosome and contiguous gene disorders			
Disease	Locus	Incidence	Clinical features
<b>Numerical chromosomal abnormalities</b>			
Down syndrome (trisomy 21)	47,XY,+21 or 47,XX,+21	1 in 800	Characteristic facies, IQ usually < 50, congenital heart disease, reduced life expectancy
Edwards syndrome (trisomy 18)	47,XY,+18 or 47,XX,+18	1 in 6000	Early lethality, characteristic skull and facies, frequent malformations of heart, kidney and other organs
Patau syndrome (trisomy 13)	47,XY,+13 or 47, XX,+13	1 in 15000	Early lethality, cleft lip and palate, polydactyly, small head, frequent congenital heart disease
Klinefelter syndrome	47,XXY	1 in 1000	Phenotypic male, infertility, gynaecomastia, small testes
XYY	47,XYY	1 in 1000	Usually asymptomatic, some impulse control problems
Triple X syndrome	47,XXX	1 in 1000	Usually asymptomatic, may have reduced IQ
Turner syndrome	45,X	1 in 5000	Phenotypic female, short stature, webbed neck, coarctation of the aorta, primary amenorrhoea
<b>Recurrent deletions, microdeletions and contiguous gene defects</b>			
Di George/velocardiofacial syndrome	22q11.2	1 in 4000	Cardiac outflow tract defects, distinctive facial appearance, thymic hypoplasia, cleft palate and hypocalcaemia. Major gene seems to be <i>TBX1</i> (cardiac defects and cleft palate)
Prader–Willi syndrome	15q11–q13	1 in 15000	Distinctive facial appearance, hyperphagia, small hands and feet, distinct behavioural phenotype. Imprinted region, deletions on paternal allele in 70% of cases
Angelman syndrome	15q11–q13	1 in 15000	Distinctive facial appearance, absent speech, electroencephalogram (EEG) abnormality, characteristic gait. Imprinted region, deletions on maternal allele encompassing <i>UBE3A</i>
Williams syndrome	7q11.23	1 in 10000	Distinctive facial appearance, supravalvular aortic stenosis, learning disability and infantile hypercalcaemia. Major gene for supravalvular aortic stenosis is <i>elastin</i>
Smith–Magenis syndrome	17p11.2	1 in 25000	Distinctive facial appearance and behavioural phenotype, self-injury and rapid eye movement (REM) sleep abnormalities. Major gene seems to be <i>RAI1</i>

**A** How structural chromosomal anomalies are described

**B** Mechanism underlying recurrent deletions and duplication: non-allelic homologous recombination

**Fig. 3.7 Chromosomal analysis and structural chromosomal disorders.** **A** Human chromosomes can be classed as metacentric if the centromere is near the middle, or acrocentric if the centromere is at the end. The bands of each chromosome are given a number, starting at the centromere and working out along the short (p) arm and long (q) arm. Translocations and inversions are balanced structural chromosome anomalies where no genetic material is missing but it is in the wrong order. Translocations can be divided into reciprocal (direct swap of chromosomal material between non-homologous chromosomes) and Robertsonian (fusion of acrocentric chromosomes). Deletions and duplications can also occur due to non-allelic homologous recombination (illustrated in part B). Deletions are classified as interstitial if they lie within a chromosome, and terminal if the terminal region of the chromosome is affected. Duplications can be either in tandem (where the duplicated fragment is inserted next to the region that is duplicated and orientated in the correct direction) or inverted (where the duplicated fragment is in the wrong direction). (N = normal; A = abnormal) **B** A common error of meiotic recombination, known as non-allelic homologous recombination, can occur (right panel), resulting in a deletion on one chromosome and a duplication in the homologous chromosome. The error is induced by tandem repeats in the DNA sequences (green), which can misalign and bind to each other, thereby ‘fooling’ the DNA into thinking the pairing prior to recombination is correct.

## Normal genomic variation

We each have 3–5 million variants in our genome, occurring approximately every 300 bases. These variants are mostly polymorphisms, arising in more than 1% of the population; they have no or subtle effects on gene and cell function, and are not associated with a high risk of disease. Polymorphisms can occur within exons, introns or the intergenic regions that comprise 98%–99% of the human genome. Each of the classes of genetic variant discussed in this chapter (Box 3.1) is present in the genome as a common polymorphism. However, the most frequent is the single nucleotide polymorphism, or SNP (pronounced 'snip'), describing the substitution of a single base.

## Polymorphisms and common disease

The protective and detrimental polymorphisms associated with common disease have been identified primarily through genome-wide association studies (GWAS, p. 52) and are the basis for many direct-to-consumer tests that purport to determine individual risk profiles for common diseases or traits such as cardiovascular disease, diabetes and even male-pattern baldness! An example is the polymorphism in the gene *SLC2A9* that not only explains a significant proportion of the normal population variation in serum urate concentration but also predisposes 'high-risk' allele carriers to the development of gout. However, the current reality is that, until we have a more comprehensive understanding of the full genomic landscape and knowledge of the complete set of detrimental and protective polymorphisms, we cannot accurately assess risk.

## Evolutionary selection

Genetic variants play an important role in evolutionary selection, with advantageous variants resulting in positive selection via improved

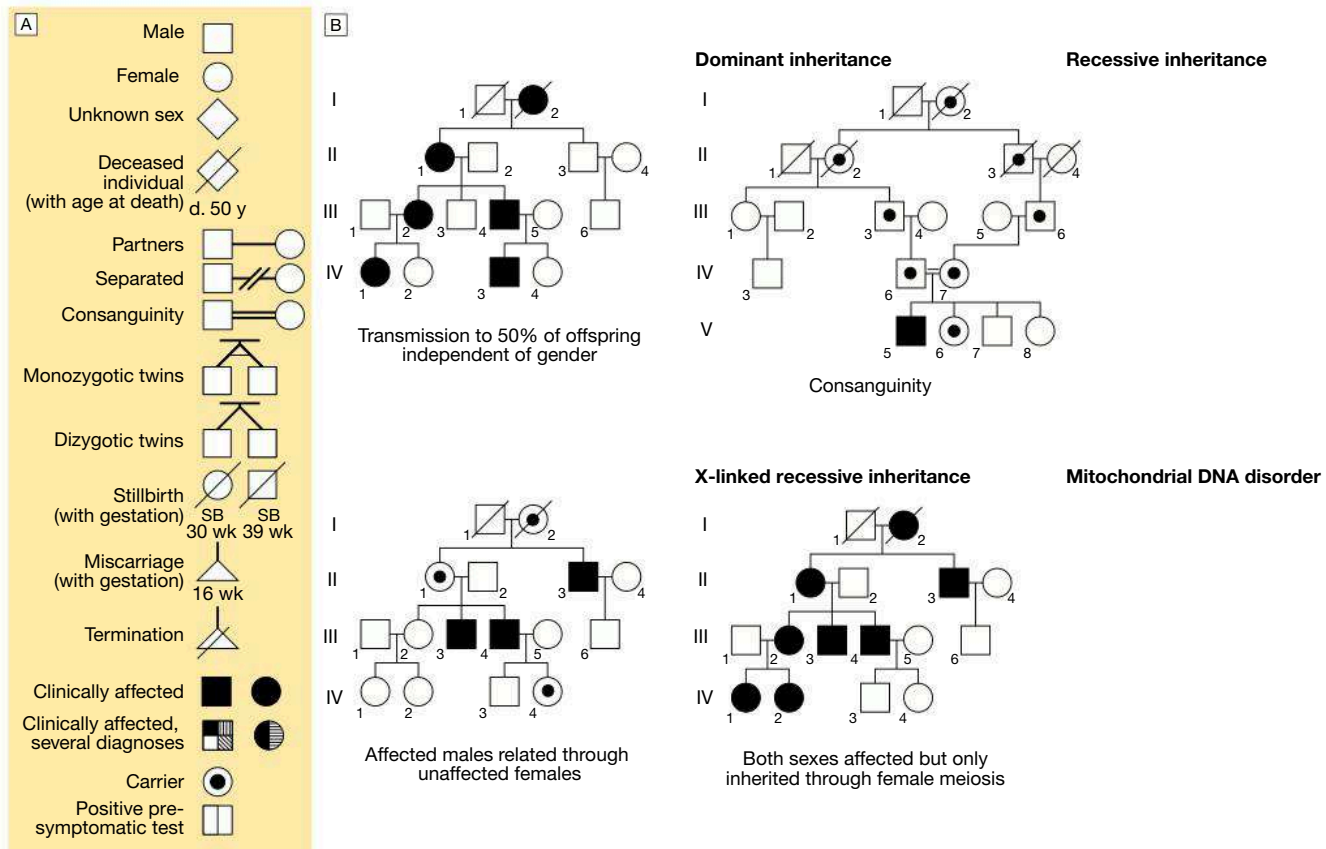

reproductive fitness, and variations that decrease reproductive fitness becoming excluded through evolution. Given this simple paradigm, it would be tempting to assume that common variants are all advantageous and all rare variants are pathogenic. Unfortunately, it is often difficult to classify any common variant as either advantageous or deleterious – or, indeed, neutral. Variants that are advantageous in early life and thus enhance reproductive fitness may be deleterious in later life. There may be variants that are advantageous for survival in particular conditions (e.g. famine or pandemic) that may be disadvantageous in more benign circumstances by causing a predisposition to obesity or autoimmune disorders.

## Constitutional genetic disease

Familial genetic disease is caused by constitutional variants, which are inherited through the germ line. However, different variants in the same gene can have different consequences, depending on the genetic mechanism underlying that disease. About 1% of the human population carries constitutional pathogenic variants that cause disease.

## Constructing a family tree

The family tree – or pedigree – is a fundamental tool of the clinical geneticist, who will routinely take a three-generation family history, on both sides of the family, enquiring about details of all medical conditions in family members, consanguinity, dates of birth and death, and any history of pregnancy loss or infant death. The basic symbols and nomenclature used in drawing a pedigree are shown in Fig. 3.8.

**Fig. 3.8** Drawing a pedigree and patterns of inheritance. **A** The main symbols used to represent pedigrees in diagrammatic form. **B** The main modes of disease inheritance (see text for details).

## Patterns of disease inheritance

### Autosomal dominant inheritance

Take some time to draw out the following pedigree:

Anne is referred to Clinical Genetics to discuss her personal history of colon cancer (she was diagnosed at the age of 46 years) and family history of colon/endometrial cancer: her mother was diagnosed with endometrial cancer at the age of 60 years and her cousin through her healthy maternal aunt was diagnosed with colon cancer in her fifties. Both her maternal grandmother and grandfather died of 'old age'. There is no family history of note on her father's side of the family. He has one brother and both his parents died of old age, in their eighties. Anne has two healthy daughters, aged 12 and 14 years, and a healthy full sister.

This family history is typical of an autosomal dominant condition (see Fig. 3.8): in this case, a colon/endometrial cancer susceptibility syndrome known as Lynch syndrome, associated with disruption of one of the mismatch repair genes: *MSH2*, *MSH6*, *MLH1* and *PMS2* (see Ch. 23 and Box 3.11).

Features of an autosomal dominant pedigree include:

- There are affected individuals in each generation (unless the pathogenic variant has arisen de novo, i.e. for the first time in an affected individual). However, variable penetrance and expressivity can influence the number of affected individuals and the severity of disease in each generation. Penetrance is defined as the proportion of individuals bearing a mutated allele who develop the disease phenotype. The variant is said to be fully penetrant if all individuals who inherit a variant develop the disease. Expressivity describes the level of severity of each aspect of the disease phenotype.
- Males and females are usually affected in roughly equal numbers (unless the clinical presentation of the condition is gender-specific, such as an inherited susceptibility to breast and/or ovarian cancer).

The offspring risk for an individual affected with an autosomal dominant condition is 1 in 2 (or 50%). This offspring risk is true for each pregnancy, since half the affected individual gametes (sperm or egg cells) will contain the affected chromosome/gene and half will contain the normal chromosome/gene.

There is a long list of autosomal dominant conditions, some of which are shown in Box 3.4.

### Autosomal recessive inheritance

As above, take some time to draw a pedigree representing the following:

Mr and Mrs Kent, a non-consanguineous couple, are referred because their son, Jamie, had severe neonatal liver disease. Included among the many investigations that the paediatric hepatologist undertook was testing for  $\alpha_1$ -antitrypsin deficiency (Box 3.5). Jamie was shown to have the PiZZ phenotype. Testing confirmed both parents as carriers with PiMZ phenotypes. In the family, Jamie has an older sister who has no medical problems. Mr Kent is one of four children with two brothers and a sister and Mrs Kent has a younger brother. Both sets of grandparents are alive and well. There is no family history of  $\alpha_1$ -antitrypsin deficiency.

This family history is characteristic of an autosomal recessive disorder (see Fig. 3.8), where both alleles of a gene must be mutated before the disease is manifest in an individual; an affected individual inherits one mutant allele from each of their parents, who are therefore healthy carriers for the condition. An autosomal recessive condition might be suspected in a family where:

- Males and females are affected in roughly equal proportions.
- Parents are blood-related; this is known as consanguinity. Where there is consanguinity, the variant are usually homozygous, i.e. the same mutant allele is inherited from both parents.
- Individuals within one sibship in one generation are affected and so the condition can appear to have arisen 'out of the blue'.

## 3.4 Genetic conditions dealt with by clinicians in other specialties

Name of condition	Gene	Reference
<b>Autosomal dominant conditions</b>		
Autosomal dominant polycystic kidney disease (ADPKD)	<i>PKD1</i> (85%), <i>PKD2</i> (15%)	p. 579 <a href="#">Box 18.28</a>
Tuberous sclerosis	<i>TSC1</i> <i>TSC2</i>	p. 1114
Marfan syndrome	<i>FBN1</i>	p. 445
Long QT syndrome	<i>KCNQ1</i>	p. 418
Brugada syndrome	<i>SCN5A</i>	p. 418
Neurofibromatosis type 1	<i>NF1</i>	p. 1185 <a href="#">Box 28.76</a>
Neurofibromatosis type 2	<i>NF2</i>	p. 1185 <a href="#">Box 28.76</a>
Hereditary spherocytosis	<i>ANK1</i>	p. 956
Vascular Ehlers–Danlos syndrome (EDS type 4)	<i>COL3A1</i>	p. 980
Hereditary haemorrhagic telangiectasia	<i>ENG</i> , <i>ALK1</i> , <i>GDF2</i>	p. 980
Osteogenesis imperfecta	<i>COL1A1</i> , <i>COL1A2</i>	p. 1058
Charcot–Marie–Tooth disease	<i>PMP22</i> , <i>MPZ</i> , <i>GJB1</i>	p. 1193
Hereditary neuropathy with liability to pressure palsies	<i>PMP22</i>	
<b>Autosomal recessive conditions</b>		
Familial Mediterranean fever	<i>MEFV</i>	p. 76
Mevalonic aciduria (mevalonate kinase deficiency)	<i>MVK</i>	p. 76
Autosomal recessive polycystic kidney disease (ARPKD)	<i>PKHD1</i>	<a href="#">Box 18.28</a>
Kartagener syndrome (primary ciliary dyskinesia)	<i>DNAI1</i>	<a href="#">Box 17.30</a>
Cystic fibrosis	<i>CFTR1</i>	p. 510 <a href="#">Box 17.30</a> p. 854
Pendred syndrome	<i>SLC26A4</i>	p. 667
Congenital adrenal hyperplasia-21 hydroxylase deficiency	<i>CYP21A</i>	p. 689 <a href="#">Box 20.27</a>
Haemochromatosis	<i>HFE</i>	p. 906
Wilson's disease	<i>ATP7B</i>	p. 907
Alpha-1-antitrypsin deficiency	<i>SERPINA1</i>	p. 908
Gilbert syndrome	<i>UGT1A1</i>	p. 908
Benign recurrent intrahepatic cholestasis	<i>ATP8B1</i>	p. 912
Alpha-thalassaemia	<i>HBA1</i> , <i>HBA2</i>	p. 962
Beta-thalassaemia	<i>HBB</i>	p. 962
Sickle cell disease	<i>HBB</i>	p. 960
Spinal muscular atrophy	<i>SMN1</i>	p. 1171
<b>X-linked conditions</b>

### 3.5 Alpha-1-antitrypsin deficiency

#### Inheritance pattern

- Autosomal recessive

#### Genetic cause

- Two common variants in the *SERPINA1* gene: p.Glu342Lys and p.Glu264Val

#### Prevalence

- 1 in 1500–3000 of European ancestry

#### Clinical presentation

- Variable presentation from neonatal period through to adulthood
- Neonatal period: prolonged jaundice with conjugated hyperbilirubinaemia or (rarely) liver disease
- Adulthood: pulmonary emphysema and/or cirrhosis. Rarely, the skin disease, panniculitis, develops

#### Disease mechanism

- SERPINA1* encodes  $\alpha_1$ -antitrypsin, which protects the body from the effects of neutrophil elastase. The symptoms of  $\alpha_1$ -antitrypsin deficiency result from the effects of this enzyme attacking normal tissue

#### Disease variants

- M variant: if an individual has normal *SERPINA1* genes and produces normal levels of  $\alpha_1$ -antitrypsin, they are said to have an M variant
- S variant: p.Glu264Val variant results in  $\alpha_1$ -antitrypsin levels reduced to about 40% of normal
- Z variant: p.Glu342Lys variant results in very little  $\alpha_1$ -antitrypsin
- PiZZ: individuals who are homozygous for the p.Glu342Lys variant are likely to have  $\alpha_1$ -antitrypsin deficiency and the associated symptoms
- PiZS: individuals who are compound heterozygous for p.Glu342Lys and p.Glu264Val are likely to be affected, especially if they smoke, but usually to a milder degree

### 3.6 Duchenne muscular dystrophy

#### Inheritance pattern

- X-linked recessive

#### Genetic cause

- Deletions/variants encompassing/within the *DMD* (dystrophin) gene located at Xp21

#### Prevalence

- 1 in 3000–4000 live male births

#### Clinical presentation

- Delayed motor milestones
- Speech delay
- Grossly elevated creatine kinase levels (in the thousands)
- Ambulation is usually lost between the ages of 7 and 13 years
- Lifespan is reduced, with a mean age of death, usually from respiratory failure, in the mid-twenties
- Cardiomyopathy affects almost all boys with Duchenne muscular dystrophy and some female carriers

#### Disease mechanism

- DMD* encodes dystrophin, a major structural component of muscle
- Dystrophin links the internal cytoskeleton to the extracellular matrix

#### Disease variants

- Becker muscular dystrophy, although a separate disease, is also caused by variants in the dystrophin gene
- In Duchenne muscular dystrophy, there is no dystrophin protein, whereas in Becker muscular dystrophy there is a reduction in the amount or alteration in the size of the dystrophin protein

Approximately 1 in 4 children born to carriers of an autosomal recessive condition will be affected. The offspring risk for carrier parents is therefore 25% and the chances of an unaffected child, with an affected sibling, being a carrier is 2/3.

Examples of some autosomal recessive conditions, discussed elsewhere in this book, are shown in Box 3.4.

### X-linked inheritance

The following is an exemplar of an X-linked recessive pedigree (see Fig. 3.8):

Edward has a diagnosis of Duchenne muscular dystrophy (DMD, Box 3.6). His parents had suspected the diagnosis when he was 3 years old because he was not yet walking and there was a family history of DMD: Edward's maternal uncle had been affected and died at the age of 24 years. Edward's mother has no additional siblings. After Edward demonstrated a very high creatinine kinase level, the paediatrician also requested genetic testing, which identified a deletion of exons 2–8 of the dystrophin gene. Edward has a younger, healthy sister and grandparents on both sides of the family are well, although the maternal grandmother has recently developed a cardiomyopathy. Edward's father has an older sister and an older brother who are both well.

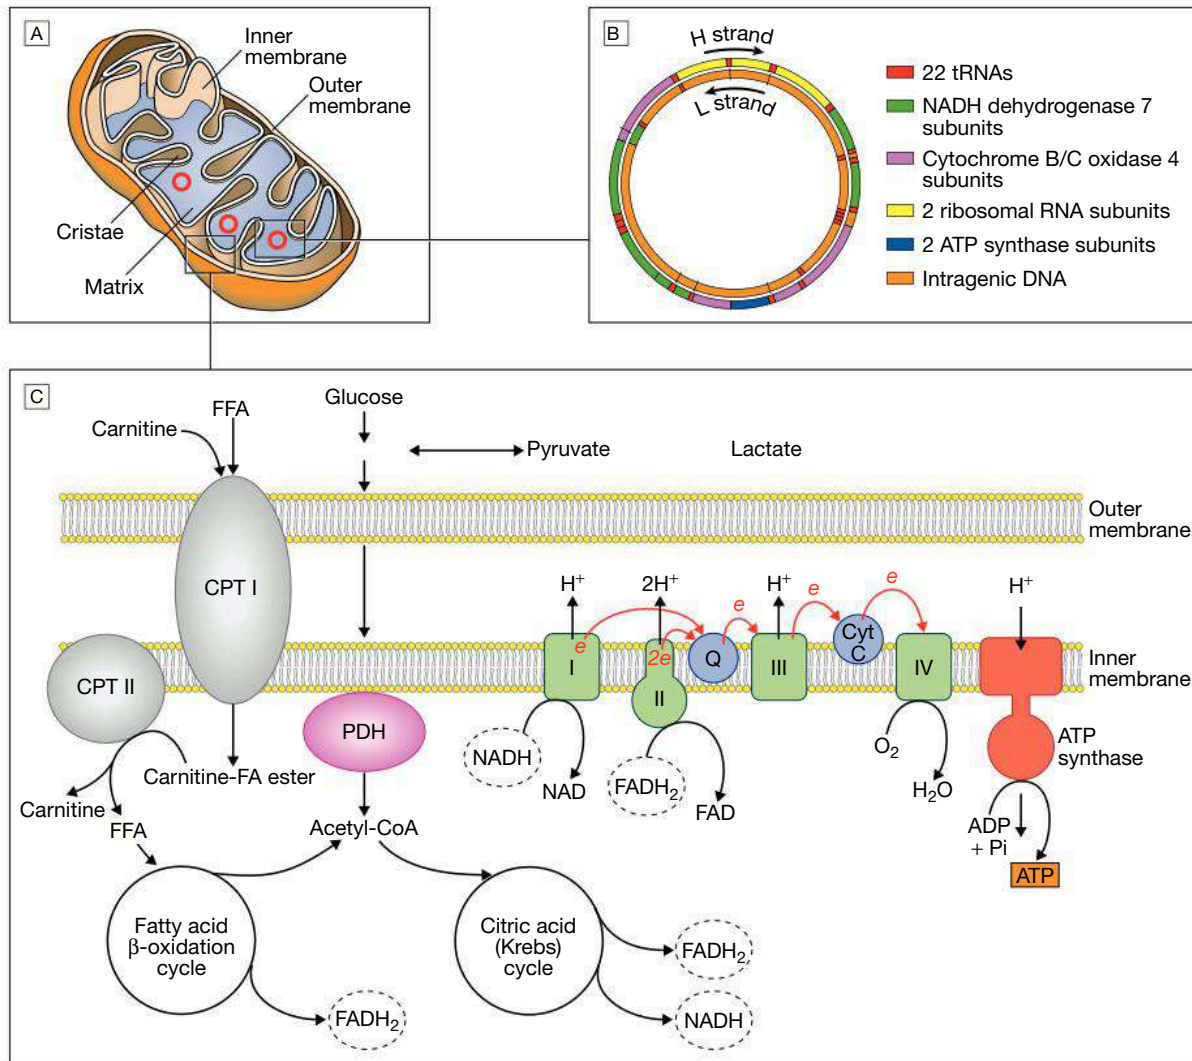

Genetic diseases caused by variants on the X chromosome have specific characteristics:

- X-linked diseases are mostly recessive and predominantly affect males who carry the mutant allele. This is because males have only one X chromosome, whereas females have two (see Fig. 3.1). Occasionally, female carriers may exhibit signs of an X-linked disease due to a phenomenon called skewed X-inactivation. All female embryos, at about 100 cells in size, stably inactivate one of their two X chromosomes in each cell. Where this inactivation is random, approximately 50% of the cells will express the genes from one X chromosome and 50% of cells will express genes from the other. Where there is a mutant gene, there is often skewing away from the associated X chromosome, resulting in an unaffected female carrier. However, if, by chance, there is a disproportionate inactivation of the normal X chromosome with skewing towards the mutant allele, then an affected female carrier may be affected (albeit more mildly than males).
- The gene can be transmitted from female carriers to their sons: in families with an X-linked recessive condition, there are often a number of affected males related through unaffected females.
- Affected males cannot transmit the condition to their sons (but all their daughters would be carriers).

The risk of a female carrier having an affected child is 25% or half of her male offspring.

### Mitochondrial inheritance

The mitochondrion is the main site of energy production within the cell. Mitochondria arose during evolution via the symbiotic association with an intracellular bacterium. They have a distinctive structure with functionally distinct inner and outer membranes. Mitochondria produce energy in the form of adenosine triphosphate (ATP). ATP is mostly derived from the metabolism of glucose and fat (Fig. 3.9). Glucose cannot enter mitochondria directly but is first metabolised to pyruvate via glycolysis. Pyruvate is then imported into the mitochondrion and metabolised to acetyl-co-enzyme A (acetyl-CoA). Fatty acids are transported into the mitochondria following conjugation with carnitine and are sequentially catabolised by a process called  $\beta$ -oxidation to produce acetyl-CoA. The acetyl-CoA from both pyruvate and fatty acid oxidation is used in the citric acid (Krebs) cycle – a series of enzymatic reactions that produces  $\text{CO}_2$ , the reduced form of nicotinamide adenine dinucleotide (NADH) and the reduced form of flavin adenine dinucleotide ( $\text{FADH}_2$ ). Both NADH and  $\text{FADH}_2$  then donate electrons to the respiratory chain. Here these electrons are transferred via a complex series of reactions, resulting in the formation of a proton gradient across the inner mitochondrial membrane. The gradient is used by an inner mitochondrial membrane protein, ATP synthase, to produce ATP, which is then transported to other parts of the cell. Dephosphorylation of ATP is used to produce the energy required for many cellular processes.

**Fig. 3.9 Mitochondria.** **A** Mitochondrial structure. There is a smooth outer membrane surrounding a convoluted inner membrane, which has inward projections called cristae. The membranes create two compartments: the inter-membrane compartment, which plays a crucial role in the electron transport chain, and the inner compartment (or matrix), which contains mitochondrial DNA and the enzymes responsible for the citric acid (Krebs) cycle and the fatty acid  $\beta$ -oxidation cycle. **B** Mitochondrial DNA. The mitochondrion contains several copies of a circular double-stranded DNA molecule, which has a non-coding region, and a coding region that encodes the genes responsible for energy production, mitochondrial transfer RNA (tRNA) molecules and mitochondrial ribosomal RNA (rRNA) molecules. **C** Mitochondrial energy production. Fatty acids enter the mitochondrion conjugated to carnitine by carnitine-palmitoyl transferase type 1 (CPT I) and, once inside the matrix, are unconjugated by CPT II to release free fatty acids (FFA). These are broken down by the  $\beta$ -oxidation cycle to produce acetyl-co-enzyme A (acetyl-CoA). Pyruvate can enter the mitochondrion directly and is metabolised by pyruvate dehydrogenase (PDH) to produce acetyl-CoA. The acetyl-CoA enters the Krebs cycle, leading to the production of NADH and flavine adenine dinucleotide (reduced form) ( $\text{FADH}_2$ ), which are used by proteins in the electron transport chain to generate a hydrogen ion gradient across the inter-membrane compartment. Reduction of NADH and  $\text{FADH}_2$  by proteins I and II, respectively, releases electrons ( $e^-$ ), and the energy released is used to pump protons into the inter-membrane compartment. Coenzyme  $\text{Q}_{10}$  (ubiquinone (Q)) is an intensely hydrophobic electron carrier that is mobile within the inner membrane. As electrons are exchanged between proteins in the chain, more protons are pumped across the membrane, until the electrons reach complex IV (cytochrome oxidase), which uses the energy to reduce oxygen to water. The hydrogen ion gradient is used to produce ATP by the enzyme ATP synthase, which consists of a proton channel and catalytic sites for the synthesis of ATP from ADP. When the channel opens, hydrogen ions enter the matrix down the concentration gradient, and energy is released that is used to make ATP. (ATP = adenosine triphosphate; NADH = the reduced form of nicotinamide adenine dinucleotide)

Each mitochondrion contains 2–10 copies of a 16-kilobase (kB) double-stranded circular DNA molecule (mtDNA). This mtDNA contains 13 protein-coding genes, all involved in the respiratory chain, and the ncRNA genes required for protein synthesis within the mitochondria (see Fig. 3.9). The mutational rate of mtDNA is relatively high due to the lack of protection by chromatin. Several mtDNA diseases characterised by defects in ATP production have been described. Mitochondria are most numerous in cells with high metabolic demands, such as muscle, retina and the basal ganglia, and these tissues tend to be the ones most severely affected in mitochondrial diseases (Box 3.7). There are many other mitochondrial diseases that are caused by pathogenic variants in nuclear genes, which encode proteins that are then imported into the mitochondrion and are critical for

energy production, e.g. most forms of Leigh syndrome (although Leigh syndrome may also be caused by a mitochondrial gene variant).

The inheritance of mtDNA disorders is characterised by transmission from females, but males and females generally are equally affected (see Fig. 3.8). Unlike the other inheritance patterns mentioned above, mitochondrial inheritance has nothing to do with meiosis but reflects the fact that mitochondrial DNA is transmitted by oocytes: sperm do not contribute mitochondria to the zygote. Mitochondrial disorders tend to be variable in penetrance and expressivity within families, and this is mostly accounted for by the fact that only a proportion of multiple mtDNA molecules within mitochondria contain the causal variant (the degree of mtDNA heteroplasmy).

## Imprinting

Several chromosomal regions (loci) have been identified where gene expression is inherited in a parent-of-origin-specific manner; these are called imprinted loci. Within these loci the paternally inherited gene may

be active while the maternally inherited may be silenced, or vice versa. Variants within imprinted loci lead to an unusual pattern of inheritance where the phenotype is manifest only if inherited from the parent who contributes the transcriptionally active allele. Examples of imprinting disorders are given in Box 3.8.

3

<b>i</b> 3.7 The structure of the respiratory chain complexes and the diseases associated with their dysfunction				
Complex	Enzyme	nDNA subunits <sup>1</sup>	mtDNA subunits <sup>2</sup>	Diseases
I	NADH dehydrogenase	38	7	MELAS, MERRF bilateral striatal necrosis, LHON, myopathy and exercise intolerance, parkinsonism, Leigh syndrome, exercise myoglobinuria, leucodystrophy/myoclonic epilepsy
II	Succinate dehydrogenase	4	0	Phaeochromocytoma, Leigh syndrome
III	Cytochrome bc <sub>1</sub> complex	10	1	Parkinsonism/MELAS, cardiomyopathy, myopathy, exercise myoglobinuria, Leigh syndrome
IV	Cytochrome c oxidase	10	3	Sideroblastic anaemia, myoclonic ataxia, deafness, myopathy, MELAS, MERRF mitochondrial encephalomyopathy, motor neuron disease-like, exercise myoglobinuria, Leigh syndrome
V	ATP synthase	14	2	Leigh syndrome, NARP, bilateral striatal necrosis

<sup>1</sup>nDNA subunits. <sup>2</sup>mtDNA subunits = number of different protein subunits in each complex that are encoded in the nDNA and mtDNA, respectively.  
 (ATP = adenosine triphosphate; LHON = Leber hereditary optic neuropathy; MELAS = myopathy, encephalopathy, lactic acidosis and stroke-like episodes; MERRF = myoclonic epilepsy and ragged red fibres; mtDNA = mitochondrial DNA; NADH = the reduced form of nicotinamide adenine dinucleotide; NARP = neuropathy, ataxia and retinitis pigmentosa; nDNA = nuclear DNA)

## Somatic genetic disease

Somatic variants are not inherited but instead occur during post-zygotic mitotic cell divisions at any point from embryonic development to late adult life. An example of this phenomenon is polyostotic fibrous dysplasia (McCune–Albright syndrome), in which a somatic variant in the G<sub>s</sub> alpha gene causes constitutive activation of downstream signalling, resulting in focal lesions in the skeleton and endocrine dysfunction.

The most important example of human disease caused by somatic variants is cancer (see Ch. 7). Here, 'driver mutations' occur within genes that are involved in regulating cell division or apoptosis, resulting in abnormal cell growth and tumour formation. The two general categories of cancer-causing variant are gain-of-function variants in growth-promoting genes (oncogenes) and loss-of-function variants in growth-suppressing genes (tumour suppressor genes). Whichever mechanism is acting, most tumours require an initiating variant in a single cell that can then escape from normal growth controls. This cell replicates more frequently or fails to undergo programmed death, resulting in clonal expansion. As the size of the clone increases, one or more cells may acquire additional variants that confer a further growth advantage, leading to proliferation of these subclones, which may ultimately result in aggressive metastatic cancer. The cell's complex self-regulating machinery means that more than one variant is usually required to produce a malignant tumour (see Fig. 7.3). For example, if a variant results in activation of a growth factor gene or receptor, then that cell will replicate more frequently as a result of autocrine stimulation. However, this mutant cell will still be subject to normal cell-cycle checkpoints to promote DNA integrity in its progeny. If additional variants in the same cell result in defective cell-cycle checkpoints, however, it will rapidly accumulate further genomic variants, which may allow completely unregulated growth and/or separation from its matrix and cellular attachments and/or resistance to apoptosis. As cell growth becomes increasingly dysregulated, cells de-differentiate, lose their response to normal tissue environment and cease to ensure appropriate mitotic chromosomal segregation. These processes combine to generate the classical malignant characteristics of disorganised growth, variable levels of differentiation and numerical and structural chromosome abnormalities. An increase in somatic variant rate can occur on exposure to external mutagens, such as ultraviolet light or cigarette smoke, or if the cell has defects in DNA repair systems. Cancer is thus a disease that affects the fundamental processes of molecular and cell biology.

<b>i</b> 3.8 Imprinting disorders			
Disorder	Locus	Genes	Notes
<b>Beckwith–Wiedemann syndrome</b>	11p15	<i>CDKN1C</i> , <i>IGF2</i> , <i>H19</i>	Increased growth, macroglossia, hemihypertrophy, abdominal wall defects, ear lobe pits/creases and increased susceptibility to developing childhood tumours
<b>Prader–Willi syndrome</b>	15q11–q13	<i>SNRPN</i> , <i>Necdin</i> and others	Obesity, hypogonadism and learning disability. Lack of paternal contribution (due to deletion of paternal 15q11–q13, or inheritance of both chromosome 15q11–q13 regions from the mother)
<b>Angelman syndrome (AS)</b>	15q11–q13	<i>UBE3A</i>	Severe mental retardation, ataxia, epilepsy and inappropriate laughing bouts. Due to loss-of-function variants in the maternal <i>UBE3A</i> gene. The neurological phenotype results because most tissues express both maternal and paternal alleles of <i>UBE3A</i> , whereas the brain expresses predominantly the maternal allele
<b>Pseudohypoparathyroidism</b>	20q13	<i>GNAS1</i>	Inheritance of the variant from the mother results in hypocalcaemia, hyperphosphataemia, raised parathyroid hormone (PTH) levels, ectopic calcification, obesity, delayed puberty and shortened 4th and 5th metacarpals (the syndrome known as Albright hereditary osteodystrophy, AHO). When the gene variant is inherited from the father, PTH, calcium and phosphate levels are normal but the other features are present. These differences are due to the fact that, in the kidney (the main target organ through which PTH regulates serum calcium and phosphate), the paternal allele is silenced and the maternal allele is expressed, whereas both alleles are expressed in other tissues

## Interrogating the genome: the changing landscape of genomic technologies

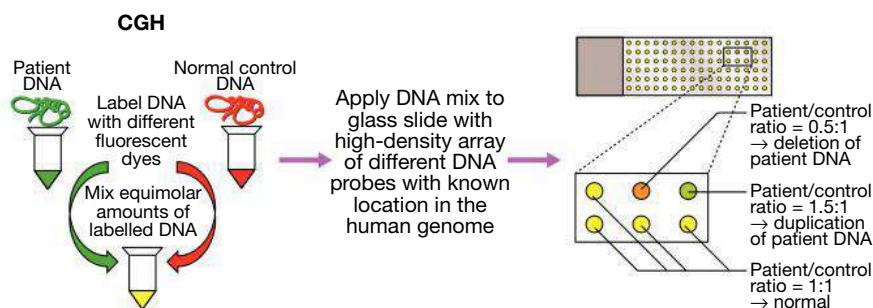

### Looking at chromosomes

The analysis of metaphase chromosomes by light microscopy was the mainstay of clinical cytogenetic analysis for decades, the aim being to detect gain or loss of whole chromosomes (aneuploidy) or large chromosomal segments (>4 million bp). More recently, genome-wide microarrays (array comparative genomic hybridisation or array CGH) have replaced chromosome analysis, allowing rapid and precise detection of segmental gain or loss of DNA throughout the genome (see [Box 3.3](#)). Microarrays consist of grids of multiple wells containing short DNA sequences (reference DNA) that are complementary to known sequences in the genome. Patient and reference DNA are each labelled with a coloured fluorescent dye (generally, patient DNA is labelled with a green fluorescent dye and reference DNA with a red fluorescent dye) and added to the microarray grid. Where there is an equal quantity of patient and reference DNA bound to the spot, this results in yellow fluorescence. Where there is too much patient DNA (representing a duplication of a chromosome region), the spot will be greener; it will be more red (appears orange) where there is 2:1 ratio of the control:patient DNA (representing heterozygous deletion of a chromosome region; [Fig. 3.10](#)).

Array CGH and other array-based approaches can detect small chromosomal deletions and duplications. They are also generally more sensitive than conventional karyotyping at detecting mosaicism (where there are two or more populations of cells, derived from a single fertilised egg, with different genotypes). However, array-based approaches will not detect balanced chromosome rearrangements where there is no loss or gain of genes/chromosome material, such as balanced reciprocal translocations, or a global increase in copy number, such as triploidy.

The widespread use of array-based approaches has brought a number of challenges for clinical interpretation, including the identification of copy number variants (CNVs) of uncertain clinical significance, CNVs of variable penetrance and incidental findings. A CNV of uncertain clinical significance describes a loss or gain of chromosome material where there are insufficient data to conclude whether or not it is associated with a learning disability and/or medical problems. While this uncertainty can be difficult to prepare families for and can be associated with considerable anxiety, it is likely that there will be greater clarity in the future as we generate larger CNV datasets.

A CNV of variable penetrance, also known as a neurosusceptibility locus, describes a chromosome deletion or duplication associated with a lower threshold for manifesting a learning disability or autistic spectrum disorder. CNVs of variable penetrance are therefore identified at greater frequencies among individuals with a learning disability and/or autistic spectrum disorder than in the general population. The current understanding is that additional modifying factors (genetic, environmental or stochastic) must influence the phenotypic expression of these neurosusceptibility loci.

**Fig. 3.10** Detection of chromosome abnormalities by comparative genomic hybridisation (CGH). Deletions and duplications are detected by looking for deviation from the 1:1 ratio of patient and control DNA in a microarray. Ratios in excess of 1 indicate duplications, whereas ratios below 1 indicate deletions.

Finally, an incidental CNV finding describes a deletion or duplication encompassing a gene or genes that are causative of a phenotype or risk unrelated to the presenting complaint. For instance, if, through the array CGH investigation for an intellectual disability, a deletion encompassing the *BRCA1* gene were identified, this would be considered an incidental finding.

### Looking at genes

#### Gene amplification: polymerase chain reaction

The polymerase chain reaction (PCR) is a fundamental laboratory technique that amplifies targeted sections of the human genome for further analyses – most commonly, DNA sequencing. The method utilises thermal cycling: repeated cycles of heating and cooling allow the initial separation of double-stranded DNA into two single strands (known as denaturation), each of which serves as a template during the subsequent replication step, guided by primers designed to anneal to a specific genomic region. This cycle of heating/cooling and denaturation/replication is repeated many times, resulting in the exponential amplification of DNA between primer sites ([Fig. 3.11](#)).

#### Gene sequencing

In the mid-1970s, a scientist called Fred Sanger pioneered a DNA sequencing technique ('Sanger sequencing') that determined the precise order and nucleotide type (thymine, cytosine, adenine and guanine) in a molecule of DNA. Modern Sanger sequencing uses fluorescently labelled, chain-terminating nucleotides that are sequentially incorporated into the newly synthesised DNA, generating multiple DNA chains of differing lengths. These DNA chains are subject to capillary electrophoresis, which separates them by size, allowing the fragments to be 'read' by a laser and producing a sequence chromatogram that corresponds to the target sequence ([Fig. 3.12](#)). Although transformative, Sanger sequencing was difficult and costly to scale, as exemplified by the Human Genome Project, which took 12 years to sequence the entire human genome at a cost approaching 3 billion US\$. Recently, DNA sequencing has been transformed again by a group of technologies collectively known as 'next-generation sequencing' (NGS; [Fig. 3.13](#)). This refers to a family of post-Sanger sequencing technologies that utilise the same five basic principles:

- **Library preparation:** DNA samples are fragmented (by enzyme cleavage or ultrasound) and then modified with a custom adapter sequence.
- **Amplification:** the library fragment is amplified to produce DNA clusters, each originating from a single DNA fragment. Each cluster will act as a single sequencing reaction.
- **Capture:** if an entire genome is being sequenced, this step will not be included. The capture step is required if targeted resequencing is necessary, such as for a panel gene test or an exome ([Box 3.9](#)).

**Fig. 3.11 The polymerase chain reaction (PCR).** PCR involves adding a tiny amount of the patient’s DNA to a reaction containing primers (short oligonucleotides 18–21 bp in length, which bind to the DNA flanking the region of interest) and deoxynucleotide phosphates (dATP, dCTP, dGTP, dTTP), which are used to synthesise new DNA and a heat-stable polymerase. The reaction mix is first heated to 95°C, which causes the double-stranded DNA molecules to separate. The reaction is then cooled to 50–60°C, which allows the primers to bind to the target DNA. The reaction is then heated to 72°C, at which point the polymerase starts making new DNA strands. These cycles are repeated 20–30 times, resulting in exponential amplification of the DNA fragment between the primer sites. The resulting PCR products can then be used for further analysis – most commonly, DNA sequencing (see Fig. 3.12).

- **Sequencing:** each DNA cluster is simultaneously sequenced and the data from each captured; this is known as a ‘read’ and is usually between 50 and 300 bases long (see Box 3.10 for a detailed description of the three most commonly used sequencing methods: synthesis, ligation and ion semiconductor sequencing).
- **Alignment and variant identification:** specialised software analyses read sequences and compare the data to a reference template. This is known as ‘alignment’ or ‘mapping’ and, although there are approximately 3 billion bases in the human genome, allows the remarkably accurate determination of the genomic origin where a read consists of 25 nucleotides or more. Variants are identified as differences between the read and the reference genome. For instance, if there is a different nucleotide in half the reads at a given position compared to the reference genome, this is likely to represent a heterozygous base substitution. The number of reads that align at a given point is called the ‘depth’ or ‘coverage’. The higher the read depth, the more accurate the variant call. However, in general, a depth of 30 or more reads is generally accepted as producing diagnostic-grade results.

Rather than sequencing only one small section of DNA at a time, NGS allows the analysis of many hundreds of thousands of DNA strands in a single experiment and so is also commonly referred to as multiple parallel sequencing technology. Today’s NGS machines can sequence the entire human genome in a single day at a cost of less than 1000 US\$.

**NGS capture**

Although we now have the capability to sequence the entire genome in a single experiment, whole-genome sequencing is not always the optimal use of NGS. NGS capture refers to the ‘pull-down’ of a targeted region of the genome and may constitute several to several hundred genes associated with a given phenotype (a gene panel), the exons of all known coding genes (an exome), or the exons of all coding genes known to be associated with disease (a clinical exome). Each of these targeted resequencing approaches is associated with a number of advantages and disadvantages (see Box 3.9). In order for NGS to be used for optimal patient benefit, it is essential for the clinician to have a good understanding of which test is the best one to request in any given clinical presentation.

**Challenges of NGS technologies**

Genomic technologies are transforming the way that we practise medicine, and ever faster and cheaper DNA sequencing offers increasing opportunities to prevent, diagnose and treat disease. However, genomic technologies are not without their challenges: for instance, storing the enormous quantities of data generated by NGS. While the A, C, T and G of our genomic code could be stored on the memory of a smartphone, huge computers, able to store several petabytes of data (where 1 petabyte is 1 million gigabytes of data), are required to store the information needed to generate each individual’s genome.

Even if we can store and handle these huge datasets successfully, we then need to be able to sift through the millions of normal variants to identify the single (or, rarely, several) pathogenic, disease-causing variant. While this can, to an extent, be achieved through the application of complex algorithms, these take time and considerable expertise to develop and are not infallible.

Furthermore, even after these data have been sifted by bioinformaticians, it is highly likely that clinicians will be left with some variants for which there are insufficient data to enable their definitive categorisation as either pathogenic or non-pathogenic. This may be because we simply do not know enough about the gene, because the particular variant has not previously been reported and/or it is identified in an unaffected parent. These variants must be interpreted with caution and, more usually, their interpretation will require input from a genetics expert in the context of the clinical presentation, where an ‘innocent until proven guilty’ approach is often adopted.

**Fig. 3.12 Sanger sequencing of DNA, which is very widely used in DNA diagnostics.** This is performed using polymerase chain reaction (PCR)-amplified fragments of DNA corresponding to the gene of interest. The sequencing reaction is carried out with a combination of dNTP and fluorescently labelled di-deoxy-dNTP (ddATP, ddTTP, ddCTP and ddGTP), which become incorporated into the newly synthesised DNA, causing termination of the chain at that point. The reaction products are then subject to capillary electrophoresis and the different-sized fragments are detected by a laser, producing a sequence chromatogram that corresponds to the target DNA sequence.

Finally, if we are to interrogate the entire genome or even the exome, it is foreseeable that we will routinely identify 'incidental' or secondary findings – in other words, findings not related to the initial diagnostic question. Whether or not to report these incidental findings is a topic of much debate in the UK, although there is growing support to feedback incidental findings where there is an intervention that could slow or halt development/progress of the associated disease.

### Uses of NGS

NGS is now frequently used, within diagnostic laboratories, to identify base substitutions and indels (although the latter were initially problematic). The current NGS challenge is to detect large deletions or duplications spanning several hundreds or thousands of bases and therefore exceeding any single read copy number variants and triplet repeat disorders such as those that cause Huntington's disease, myotonic dystrophy and fragile X syndrome, although techniques to detect both are improving (see Box 3.2). Increasingly, however, disorders caused by both copy number variants and triplet repeat expansions are being diagnosed using sophisticated computational methods. Additional potential uses of NGS include detection of balanced and unbalanced translocations and mosaicism: NGS has proved remarkably sensitive at detecting the latter when there is high read coverage for a given region. Of note, however, NGS is still not able to interrogate the epigenome and so will not identify conditions caused by a disruption of imprinting, such as Beckwith–Wiedemann, Silver–Russell, Angelman and Prader–Willi syndromes (see Boxes 3.8 and 3.2).

### Third-generation sequencing

Increasingly, third-generation or single-molecule sequencing is entering the diagnostic arena. As with next- or second-generation sequencing, a number of different platforms are commercially available. One of the most successful is SMRT technology (single-molecule sequencing in real time), developed by Pacific Biosciences. This system utilises a single-stranded DNA molecule (as compared to the amplified clusters used in NGS), which acts as a template for the sequential incorporation, using a polymerase, of fluorescently labelled nucleotides. As each complementary nucleotide is added, the fluorescence (and therefore the identity of the nucleotide) is recorded before it is removed and another nucleotide is added.

A key advantage of third-generation sequencing is the long length of the read it generates: in the region of 10–15 kilobases. It is also cheaper

than NGS, as fewer reagents are required. Given these inherent advantages, third-generation sequencing is likely to supersede NGS in the near future. Given the confusion surrounding the terminology of NGS and third-generation sequencing, these technologies are increasingly referred to as 'massively parallel sequencing'.

## Genomics and clinical practice

### Genomics and health care

#### Genomics in rare neurodevelopmental disorders

Although, by definition, the diagnosis of a rare disorder is made infrequently, rare diseases, when considered together, affect about 3 million people in the UK, the majority of whom are children. NGS has transformed the ability to diagnose individuals affected by a rare disease. Whereas previously, when we were restricted to the sequential analysis of single genes, a clinician would need to make a clinical diagnosis in order to target testing, NGS allows the interrogation of multiple genes in a single experiment. This might be done through a gene panel, a clinical exome or an exome (see Box 3.9 and p. 51), and has increased the diagnostic yield in neurodevelopmental disorders to 35%–50%. Not only does the identification of the genetic cause of a rare disorder potentially provide families with answers, prognostic information and the opportunity to meet and derive support from other affected families but also it can provide valuable information for those couples planning further children and wishing to consider prenatal testing in the future.

#### Genomics and common disease

Most common disorders are determined by interactions between a number of genes and the environment. In this situation, the genetic contribution to disease is termed polygenic. Until recently, very little progress had been made in identifying the genetic variants that predispose to common disorders, but this has been changed by the advent of genome-wide association studies. A GWAS typically involves genotyping many (> 500 000) genetic markers (SNPs) spread across the genome in a large group of individuals with the disease and in controls. By comparing the SNP genotypes in cases and controls, it is possible to identify regions of the genome, and therefore genes, more strongly associated with a given

**Fig. 3.13** Sequencing by synthesis as used in the Illumina system. (1) Library preparation: DNA is fragmented and specialist adapters are ligated to the fragmented ends. (2) Cluster amplification: the library is loaded to a flow cell and the adapters hybridise to the flow-cell surface. Each bound fragment is hybridised. (3) Sequencing. (4) Alignment and variant interpretation: reads are aligned to a reference sequence using complex software and differences between reference and case genomes are identified.

SNP profile and therefore more likely to contribute to the disease under study. Increasingly there is a move to develop disease-specific polygenic risk scores (PRS) in order to stratify individual risk and determine personalised management strategies. Whilst not yet in mainstream practice, it is likely that PRS will be integrated into clinical management in the next few years.

## Genomics and obstetrics

Prenatal genetic testing may be performed where a pregnancy is considered at increased risk of being affected with a genetic condition, either because of the ultrasound/biochemical screening results or because of the family history. While invasive tests, such as amniocentesis and chorionic villus sampling, have been the mainstay of prenatal diagnosis for many years, they are increasingly being superseded by non-invasive

### 3.9 The advantages and disadvantages of whole-genome sequencing, whole-exome sequencing and gene panels

Test	Advantages	Disadvantages
<b>Whole-genome sequencing (WGS)</b>	The most comprehensive analysis of the genome available More even coverage of genes, allowing better identification of dosage abnormalities Will potentially detect all gene variants, including intronic variants	More expensive to generate and store Will detect millions of variants in non-coding DNA, which can be very difficult to interpret Associated with a greater risk of identifying incidental findings Shallow sequencing (few reads per gene) and so less sensitive and less able to detect mosaicism
<b>Whole-exome sequencing (WES)</b>	Cheaper than whole-genome sequencing Analysis is not restricted to only those genes known to cause a given condition Fewer variants detected than in WGS and so easier interpretation Deeper sequencing than WGS increases sensitivity and detection of mosaicism	Less even coverage of the genome and so dosage abnormalities are more difficult to detect Less comprehensive analysis (1%–2% of the genome) than WGS Increased risk of identifying incidental findings over targeted gene sequencing
<b>Gene panels</b>	Cost-effective Very deep sequencing, increasing the chances of mosaicism being detected Fewer variants detected and so data easier to interpret As analysis is restricted to known genes, the likelihood of a variant being pathogenic is greatly increased	Will only detect variation in genes known to cause a given condition Difficult to add new genes to the panel as they are discovered

testing of cell-free fetal DNA (cffDNA), originating from placental trophoblasts and detectable in the maternal circulation from 4–5 weeks' gestation; it is present in sufficient quantities for testing by 9 weeks.

- Non-invasive prenatal testing (NIPT):** the sequencing and quantification, using NGS, of cffDNA chromosome-specific DNA sequences to identify trisomy 13, 18 or 21. The accuracy of NIPT in detecting pregnancy-specific aneuploidy approaches 98%. A false-negative result can occur when there is too little cffDNA (possibly due to early gestation or high maternal body mass index) or when aneuploidy has arisen later in development and is confined to the embryo and not represented in the placenta. False positives can occur with confined placental mosaicism (describing aneuploidy in the placenta, not the fetus) or with an alternative cause of aneuploidy in the maternal circulation, such as cell-free tumour DNA.

### 3.10 Next-generation sequencing methods

#### Sequencing by synthesis (Fig. 3.13)

- The most frequently used NGS method
- Used in Illumina systems (commonly used in diagnostic laboratories)
- Uses fluorescently labelled, terminator nucleotides that are sequentially incorporated into a growing DNA chain
- Library DNA samples (fragmented DNA flanked by DNA adapter sequences) are anchored to a flow cell by hybridisation of the DNA adapter sequence to probes on the flow-cell surface
- Amplification occurs by washing the flow cell in a mixture containing all four fluorescently labelled terminator nucleotides: A, C, T and G
- Once the nucleotide, complementary to the first base of the DNA template, is incorporated, no further nucleotides can be added until the mixture is washed away
- The nucleotide terminator is shed and the newly incorporated nucleotide reverts to a regular, non-fluorescent nucleotide that can be extended
- The process is then repeated with the incorporation of a second base etc.
- Sequencing by synthesis is therefore space- and time-dependent: a sensor will detect the order of fluorescent emissions for each spot on the plate (representing the cluster) and determine the sequence for that read

#### Sequencing by ligation

- Used in SOLiD systems
- Uses DNA ligase rather than DNA polymerase (as is used in sequencing by synthesis) and short oligonucleotides (as opposed to single nucleotides)
- Library DNA samples are washed in a mixture containing oligonucleotide probes representing 4–16 dinucleotide sequences. Only one nucleotide in the probe is fluorescently labelled
- The complementary oligo probes will hybridise, using DNA ligase, to the target sequence, initially at a primer annealed to the anchor site and then progressively along the DNA strand
- After incorporation of each probe, fluorescence is measured and the dye is cleaved off
- Eventually, a new strand is synthesised (composed of a series of the oligo probes)
- A new strand is then synthesised but is offset by one nucleotide
- The process is repeated a number of times (5 rounds in the SOLiD system), providing overlapping templates that are analysed and a composite of the target sequence determined

#### Ion semiconductor sequencing

- When a nucleotide is incorporated into a growing DNA strand, a hydrogen ion is released that can be detected by an alteration in the pH of the solution. This hydrogen ion release forms the basis of ion semiconductor sequencing
- Each amplified DNA cluster is located above a semiconductor transistor, capable of detecting differences in the pH of the solution
- The DNA cluster is washed in a mixture containing only one type of nucleotide
- If the correct nucleotide, complementary to the next base on the DNA template, is in the mixture and incorporated, a hydrogen ion is released and detected
- If a homopolymer (sequence of two or more identical nucleotides) is present, this will be detected as a decrease in pH proportionate to the number of identical nucleotides in the sequence

### 3.11 Inherited cancer predisposition syndromes

Syndrome name	Gene	Associated cancers	Additional clinical features
<b>Birt–Hogg–Dubé syndrome</b>	<i>FLCN</i>	Renal tumour (oncocytoma, chromophobe (and mixed), renal cell carcinoma)	Fibrofolliculoma Trichodiscoma Pulmonary cysts
<b>Breast/ovarian hereditary susceptibility</b>	<i>BRCA1</i> <i>BRCA2</i>	Breast carcinoma Ovarian carcinoma Pancreatic carcinoma Prostate carcinoma	
<b>Cowden syndrome</b>	<i>PTEN</i>	Breast carcinoma Thyroid carcinoma Endometrial carcinoma	Macrocephaly Intellectual disability/autistic spectrum disorder Trichilemmoma Acral keratosis Papillomatous papule Thyroid cyst Lipoma Haemangioma Intestinal hamartoma
<b>Gorlin syndrome/basal cell naevus syndrome</b>	<i>PTCH1</i>	Basal cell carcinoma Medulloblastoma	Odontogenic keratocyst Palmar or plantar pits Falx calcification Rib abnormalities (e.g. bifid, fused or missing ribs) Macrocephaly Cleft lip/palate
<b>Li–Fraumeni syndrome</b>	<i>TP53</i>	Sarcoma (e.g. osteosarcoma, chondrosarcoma, rhabdomyosarcoma) Breast carcinoma Brain cancer (esp. glioblastoma) Adrenocortical carcinoma Brain	

### 3.11 Inherited cancer predisposition syndromes

Syndrome name	Gene	Associated cancers	Additional clinical features
Lynch syndrome/hereditary non-polyposis colon cancer	<i>MLH1</i> <i>MSH2</i> <i>MSH6</i> <i>PMS2</i>	Colorectal carcinoma (majority right-sided) Endometrial carcinoma Gastric carcinoma Cholangiocarcinoma Ovarian carcinoma (esp. mucinous)	
Multiple endocrine neoplasia 1	<i>MEN1</i>	Parathyroid tumour Endocrine pancreatic tumour Anterior pituitary tumour	Lipoma Facial angiofibroma
Multiple endocrine neoplasia 2a and 2b (formerly known as type 2 and 3, respectively)	<i>RET</i>	Medullary thyroid tumour Pheochromocytoma Parathyroid tumour	
Polyposis, familial adenomatous (FAP)	<i>APC</i>	Colorectal adenocarcinoma (FAP is characterised by thousands of polyps from the second decade; without colectomy, malignant transformation of at least one of these polyps is inevitable) Duodenal carcinoma Hepatoblastoma	Desmoid tumour Congenital hypertrophy of the retinal pigment epithelium (CHRPE)
Polyposis, MYH-associated	<i>MYH</i> ( <i>MUTYH</i> )	Colorectal adenocarcinoma Duodenal adenocarcinoma	
Retinoblastoma, familial	<i>RB1</i>	Retinoblastoma Osteosarcoma	

- *Non-invasive prenatal diagnosis (NIPD)*: the identification of a fetal single-gene defect that either has been paternally inherited or has arisen de novo and so is not identifiable in the maternal genome. Examples of conditions that are currently amenable to NIPD include achondroplasia and the craniosynostoses. Increasingly, however, NIPD is being used for autosomal recessive conditions such as cystic fibrosis, where parents are carriers for different gene variants and research is under way to perform more agnostic fetal gene sequencing through whole-exome or whole-genome sequencing.

Where a genetic diagnosis is known in a family, a couple may opt to undertake pre-implantation genetic diagnosis (PGD). PGD is used as an adjunct to in vitro fertilisation and involves the genetic testing of a single cell from a developing embryo, prior to implantation.

## Genomics and oncology

Until recently, individuals were stratified to genetic testing if they presented with a personal and/or family history suggestive of an inherited cancer predisposition syndrome (Box 3.11). Relevant clinical information included the age of cancer diagnosis and number/type of tumours. For example, the diagnosis of bilateral breast cancer in a woman in her thirties with a mother who had ovarian cancer in her forties is suggestive of *BRCA1/2*-associated familial breast/ovarian cancer. In many familial cancer syndromes, somatic gene variants act together with an inherited variant to cause specific cancers (p. 49). Familial cancer syndromes may be due to germ-line loss-of-function variants in tumour suppressor genes encoding DNA repair enzymes or proto-oncogenes. At the cellular level, loss of one copy of a tumour suppressor gene does not have any functional consequences, as the cell is protected by the remaining normal copy. However, a somatic variant affecting the normal allele is likely to occur in one cell at some point during life, resulting in complete loss of tumour suppressor activity and a tumour developing by clonal expansion of that cell. This two-hit mechanism (one inherited, one somatic) for cancer development is known as the Knudson hypothesis. It explains why tumours may not develop for many years (or ever) in some members of these cancer-prone families. In DNA repair diseases, the inherited variants increase the somatic mutation rate. Autosomal dominant variants

in genes encoding components of specific DNA repair systems are relatively common causes of familial colon cancer and breast cancer (e.g. *BRCA1*).

Increasingly, genetics is moving into the mainstream, becoming integrated into routine oncological care as new gene-specific treatments are introduced. Testing for a genetic predisposition to cancer is therefore moving from the domain of clinical genetics, where it has informed diagnosis, cascade treatment and screening/prophylactic management, to oncology, where it is informing the immediate management of the patient following cancer diagnosis. This is exemplified by *BRCA1* and *BRCA2* (*BRCA1/2*)-related breast cancer. Previously, women with a pathogenic variant in either the *BRCA1* or *BRCA2* gene would have received similar first-line chemotherapy to women with a sporadic breast cancer without a known genetic association. More recently, it has been shown that *BRCA1/2* mutation-positive tumours are sensitive to poly ADP ribose polymerase (PARP) inhibitors. PARP inhibitors block the single-strand break-repair pathway. In a *BRCA1/2* mutation-positive tumour – with compromised double-strand break repair – the additional loss of the single-strand break-repair pathway will drive the cell towards apoptosis. Indeed, PARP inhibitors have been shown to be so effective at destroying *BRCA1/2* mutation-positive tumour cells, and with such minimal side-effects, that *BRCA1/2* gene testing is increasingly determining patient management. It is likely, with a growing understanding of the genomic architecture of tumours, increasing accessibility of NGS and an expanding portfolio of gene-directed therapies, that testing for many of the other inherited cancer susceptibility genes will, in time, move into the mainstream.

## Genomics in infectious disease

NGS technologies are also transforming infectious disease. Given that a microbial genome can be sequenced within a single day at a current cost of less than 100US\$, microbiologists are able to identify a causative microorganism and target effective treatment rapidly and accurately. Moreover, microbial genome sequencing enables the effective surveillance of infections to reduce and prevent transmission. Finally, an understanding of the microbial genome will drive the development of vaccines and antibiotics, essential in an era characterised by increasing microbial resistance to established antibiotic agents.

## Treatment of genetic disease

### Pharmacogenomics

Pharmacogenomics is the science of dissecting the genetic determinants of drug kinetics and effects using information from the human genome. For more than 50 years it has been appreciated that polymorphic variants within genes can affect individual responses to some drugs, such as loss-of-function variants in *CYP2D6* that cause hypersensitivity to debrisoquine, an adrenergic-blocking medication formerly used for the treatment of hypertension, in 3% of the population. This gene is part of a large family of highly polymorphic genes encoding cytochrome P450 proteins, mostly expressed in the liver, which determine the metabolism of a host of specific drugs. Polymorphisms in the *CYP2D6* gene also determine codeine activation, while those in the *CYP2C9* gene affect warfarin inactivation. Polymorphisms in these and other drug metabolic genes determine the persistence of drugs and, therefore, should provide information about dosages and toxicity. With the increasing use of NGS, genetic testing for assessment of drug response is seldom employed routinely, but in the near future it may be possible to predict the best specific drugs and dosages for individual patients based on genetic profiling: so-called 'personalised medicine'. An example is the enzyme thiopurine methyltransferase (TPMT), which catabolises azathioprine, a drug that is used in the treatment of autoimmune diseases and in cancer chemotherapy. Genetic screening for polymorphic variants of TPMT can be useful in identifying patients who have increased sensitivity to the effects of azathioprine and who can be treated with lower doses than normal.

### Gene therapy and genome editing

Replacing or repairing mutated genes (gene therapy) is challenging in humans. Retroviral-mediated ex vivo replacement of the defective gene in bone marrow cells for the treatment of severe combined immune deficiency syndrome has been successful. The major problems with clinical use of virally delivered gene therapy have been oncogenic integration of the exogenous DNA into the genome and severe immune response to the virus.

Other therapies for genetic disease include PTC124, a compound that can 'force' cells to read through a nonsense variant that results in a premature termination codon in an ORF with the aim of producing a near-normal protein product. This therapeutic approach could be applied to any genetic disease caused by nonsense variants.

The most exciting development in genetics for a generation has been the discovery of accurate, efficient and specific techniques to enable editing of the genome in cells and organisms. This technology is known as CRISPR/Cas9 (clustered regularly interspaced short palindromic repeats and CRISPR-associated) genome editing. It is likely that ex vivo correction of genetic disease will become commonplace over the next few years. In vivo correction is not yet possible and will take much longer to become part of clinical practice.

### Induced pluripotent stem cells and regenerative medicine

Adult stem-cell therapy has been in wide use for decades in the form of bone marrow transplantation. The identification of adult stem cells for other tissues, coupled with the ability to purify and maintain such cells in vitro, now offers exciting therapeutic potential for other diseases. It was recently discovered that many different adult cell types can be trans-differentiated to form cells (induced pluripotent stem cells or iPS cells) with almost all the characteristics of embryonic stem cells derived from the early blastocyst. In mammalian model species, such cells can be taken and used to regenerate differentiated tissue cells, such as in heart and brain. They have great potential both for the development of tissue models of human disease and for regenerative medicine.

## Pathway medicine

The ability to manipulate pathways that have been altered in genetic disease has tremendous therapeutic potential for Mendelian disease, but a firm understanding of both disease pathogenesis and drug action at a biochemical level is required. An exciting example has been the discovery that the vascular pathology associated with Marfan syndrome is due to the defective fibrillin molecules causing up-regulation of transforming growth factor (TGF)- $\beta$  signalling in the vessel wall. Losartan is an antihypertensive drug that is marketed as an angiotensin II receptor antagonist. However, it also acts as a partial antagonist of TGF- $\beta$  signalling and is effective in preventing aortic dilatation in a mouse model of Marfan syndrome, showing promising effects in early human clinical trials.

## Ethics in a genomic age

As genomic technology is increasingly moving into mainstream clinical practice, it is essential for clinicians from all specialties to appreciate the complexities of genetic testing and consider whether genetic testing is the right thing to do in a given clinical scenario. To exemplify the ethical considerations associated with genetic testing, it may be helpful to think about them in the context of a clinical scenario. As you read the scenario, try to think what counselling/ethical issues might arise:

A 32-year-old woman is referred to discuss *BRCA2* testing; she is currently pregnant with her second child (she already has a 2-year-old daughter) and has an identical twin sister. Her mother, a healthy 65-year-old with Ashkenazi Jewish ancestry, participated in direct-to-consumer testing (DCT) for 'a bit of fun' and a *BRCA2* gene variant – common in the Ashkenazi Jewish population – was identified. There is no significant cancer family history of note.

Consider the following issues:

- *Pre-symptomatic/predictive testing*: this describes testing for a known familial gene variant in an unaffected individual (compared with diagnostic testing, where genetic testing is undertaken in an affected individual). Although this could be considered for the unaffected patient, in the current scenario any testing would also have implications for her identical twin sister. This needs to be fully explored with the patient and her sister prior to testing. There is also the potential issue of predictive testing in the patient's first child. A fundamental tenet in clinical genetics is that predictive genetic testing should be avoided in childhood for adult-onset conditions. This is because, if no benefit to the patient is accrued through childhood testing, it is better to retain the child's right to decide for herself, when she is old enough, whether she wishes to participate in genetic testing or not.
- *Prenatal testing*: the principles behind predictive genetic testing in childhood can be extended to prenatal testing, i.e. if a pregnancy is being continued, a baby should not be tested for an adult-onset condition that cannot be prevented or treated in childhood. However, prenatal testing itself is hugely controversial and there is much debate as to how severe a condition should be to justify prenatal diagnosis, which would determine ongoing pregnancy decisions.
- *DCT*: while DCT can be interesting and empowering for individuals wishing to find out more about their genetic backgrounds, it also has several drawbacks. Perhaps the main one is that, unlike face-to-face genetic counselling (which usually precedes any genetic testing, certainly where there are serious health implications for the individual and their family, such as is associated with *BRCA1/2* variants), DCT is undertaken in isolation with no direct access to professional support. Furthermore, in addition to some (common) single-gene variants, such as the founder *BRCA1/2* variants frequently identified in the Ashkenazi Jewish population and discussed in this example, current DCT packages utilise a series of SNPs to determine an overall risk profile; they evaluate the number of detrimental and

protective SNPs for a given disease. However, given that only a minority of the risk SNPs have so far been characterised, this is often inaccurate. Individuals may be falsely reassured that they are not at increased risk of a genetic condition despite a family history suggesting otherwise, resulting in inadequate surveillance and/or management.

The ethical considerations listed in this clinical scenario give just a flavour of some of the issues frequently encountered in clinical genetics. They are not meant to be an exhaustive summary and whole textbooks and meetings are devoted to the discussion of hugely complex ethical issues in genetics. However, a guiding principle is that, although each counselling situation will be unique with specific communication and ethical challenges, a genetic result is permanent and has implications for the whole family, not just the individual. Where possible, therefore, an informed decision regarding genetic testing should be taken by a competent adult following counselling by an experienced and appropriately trained clinician.

## Multiple Choice Questions

3.1. Which of the following best describes a missense or non-synonymous variant?

- A. A base substitution that results in the introduction of a premature stop codon
- B. A base substitution that results in a different codon and different amino acid
- C. The deletion of two bases that results in a shift of reading frame and the introduction of a downstream premature stop codon
- D. A base substitution that introduces a cryptic splice site
- E. A base substitution that results in a different codon but same amino acid

Answer: B.

The most common type of genomic variation is the substitution of one nucleotide for another, caused by either misincorporation of a nucleotide during DNA synthesis or chemical modification of the base. If a nucleotide substitution occurs within the open reading frame of a protein-coding gene it will affect a codon within that gene. A missense/non-synonymous variant refers to a nucleotide substitution in which the effect on the codon in which it occurs is to cause it to encode a different amino acid.

3.2. Approximately how many genes are there in the average human genome?

- A. 2000
- B. 20000
- C. 200000
- D. 2000000
- E. 20000000

Answer: B.

The human genome contains over 20 000 genes. Many of these are inactive or silenced in different cell types, reflecting the variable gene expression responsible for cell-specific characteristics.

3.3. Which of the following is a cardinal feature of an X-linked recessive disorder?

- A. Male-to-male transmission
- B. Affected individuals in each generation.
- C. Increased frequency in consanguineous unions
- D. Predominantly males affected
- E. There is characteristically highly variable penetrance and expressivity in the same family

Answer: D.

In X-linked recessive diseases females who carry a copy of the mutant allele on one of their X chromosomes (unaffected carriers) will pass the allele on to 50% of their offspring. Only the male offspring will be affected, because they have only one X chromosome. The female offspring will be carriers, as they will inherit a 'normal' X chromosome from their fathers. The overall risk of a female carrier having an affected child is therefore 25%, or half of her male offspring.

Male-to-male transmission of an X-linked recessive condition does not occur because fathers will pass on their Y chromosome to their sons (not the X chromosome with mutant allele). The presence of affected individuals in each generation is a characteristic feature of autosomal dominant inheritance with full penetrance, in which half of the offspring of an affected parent will be affected irrespective of their sex. Increased frequency in consanguineous unions would suggest an autosomal recessive disorder, because the chance of both the female and the male

parent carrying the same mutant allele would be increased by consanguinity. Highly variable penetrance and expressivity in the same family is a feature of mitochondrial disorders.

3.4. Which type of genomic variant will an array comparative genomic hybridisation (CGH) best detect?

- A. A balanced chromosome translocation
- B. A frameshift variant
- C. A 2 MB deletion
- D. A missense variant
- E. An essential splice variant

Answer: C.

Array CGH allows rapid and precise detection of segmental gain or loss of DNA throughout the genome. Microarrays consist of grids of multiple wells containing short DNA sequences (reference DNA) that are complementary to known sequences in the genome. Patient and reference DNA are each labelled with a coloured fluorescent dye (generally, patient DNA is labelled with a green fluorescent dye and reference DNA with a red fluorescent dye) and added to the microarray grid. Where there is an equal quantity of patient and reference DNA bound to the spot, this results in yellow fluorescence. Where there is too much patient DNA (representing a duplication of a chromosome region), the spot will be greener; and it will be more red (appears orange) where there is a 2 : 1 ratio of the control : patient DNA (representing heterozygous deletion of a chromosome region).

Array CGH can detect small chromosomal deletions and duplications and is also more sensitive than conventional karyotyping at detecting mosaicism. However, array CGH and other array-based approaches will not detect balanced chromosome rearrangements where there is no loss or gain of genes/chromosome material, such as balanced reciprocal translocations, or a global increase in copy number, such as triploidy. In addition, an array CGH will not detect small insertions/deletions or single nucleotide substitutions.

3.5. Which of the following is an imprinted condition?

- A. Huntington's disease
- B. Patau syndrome
- C. Neurofibromatosis type 1
- D. Pseudohypoparathyroidism
- E. Alpha-1-antitrypsin deficiency

Answer: D.

Several chromosomal regions (loci) have been identified where gene expression is inherited in a parent-of-origin-specific manner; these are called imprinted loci. Within these loci the paternally inherited gene may be active while the maternally inherited may be silenced, or vice versa. Variants within imprinted loci lead to an unusual pattern of inheritance where the phenotype is manifest only if inherited from the parent who contributes the transcriptionally active allele.

Pseudohypoparathyroidism (PHP) is caused by the maternal inheritance of a *GNAS1* variant (located at 20q13) and is characterised by hypocalcaemia, hyperphosphataemia, raised parathyroid hormone (PTH) levels, ectopic calcification, obesity, delayed puberty and shortened 4th and 5th metacarpals (the syndrome also known as Albright hereditary osteodystrophy, AHO). When the gene variant is inherited from the father, PTH, calcium and phosphate levels are normal but the other (skeletal) features are present and the condition is known as pseudopseudohypoparathyroidism (PPHP). *GNAS1* encodes  $Gs\alpha$  which is primarily expressed from the maternal allele in the kidney, pituitary, thyroid and gonadal cells (and their disruption is the cause of the biochemical defects) whereas both alleles are expressed in other tissues (responsible for the skeletal features). Therefore where a *GNAS1* variant is maternally inherited the individual will have both biochemical and skeletal features (PHP) but where it is paternally inherited they will not have the biochemical features (PPHP).

### Tumour immunology 85

The immune system has evolved to identify and destroy pathogens while minimising damage to host tissue. Despite the ancient observation that recovery from an infectious disease frequently results in protection against that condition, the existence of the immune system as a functional entity was not recognised until the end of the 19th century. More recently, it has become clear that the immune system not only protects against infection but also regulates tissue repair following injury, and when dysregulated, governs the responses that can lead to auto-immune and auto-inflammatory diseases. Dysfunction or deficiency of the immune response can lead to a wide variety of diseases that may potentially involve every organ system in the body.

The aim of this chapter is to provide a general understanding of the immune system, how it contributes to human disease and how manipulation of the immune system can be put to therapeutic use. A review of the key components of the immune response is followed by sections that illustrate the clinical presentation of the most common forms of immune dysfunction: immune deficiency, inflammation, autoimmunity and allergy. More detailed discussion of individual conditions can be found in the relevant organ-specific, emergency and critical care medicine chapters

## Functional anatomy and physiology

The immune system consists of an intricately linked network of lymphoid organs, cells and proteins that are strategically placed to protect against infection (Fig. 4.1). Immune defences are normally categorised into the innate immune response, which provides immediate protection against an invading pathogen, and the adaptive or acquired immune response, which takes more time to develop but confers exquisite specificity and long-lasting protection. Innate and adaptive immunity do not work in isolation, but rather in concert, largely driven by cytokines produced by the specific immune cell populations.

## The innate immune system

Innate defences against infection include anatomical barriers, phagocytic cells, soluble molecules such as complement and acute phase proteins, and natural killer cells. The innate immune system recognises generic microbial structures present on non-mammalian tissue and can be mobilised within minutes. A specific stimulus will elicit essentially identical responses in different individuals, in contrast with adaptive antibody and T-cell responses, which vary greatly between individuals.

## Physical barriers

The tightly packed keratinised cells of the skin physically limit colonisation by microorganisms. The hydrophobic oils that are secreted by sebaceous glands further repel water and microorganisms, and microbial growth is inhibited by the skin's low pH and low oxygen tension. Sweat also contains lysozyme, an enzyme that destroys the structural integrity of bacterial cell walls; ammonia, which has antibacterial properties; and several antimicrobial peptides such as defensins. Similarly, the mucous membranes of the respiratory, gastrointestinal and genitourinary tracts provide a physical barrier to infection. Secreted mucus traps invading pathogens, and immunoglobulin A (IgA), generated by the adaptive immune system, prevents bacteria and viruses attaching to and penetrating epithelial cells. As in the skin, lysozyme and antimicrobial peptides within mucosal membranes directly kill invading pathogens, and lactoferrin acts to starve invading bacteria of iron. Within the respiratory tract, cilia directly trap pathogens and contribute to removal of mucus, assisted by physical manoeuvres such as sneezing and coughing. In the gastrointestinal tract, hydrochloric acid and salivary amylase chemically destroy bacteria, while normal peristalsis and induced vomiting or diarrhoea assist clearance of invading organisms.

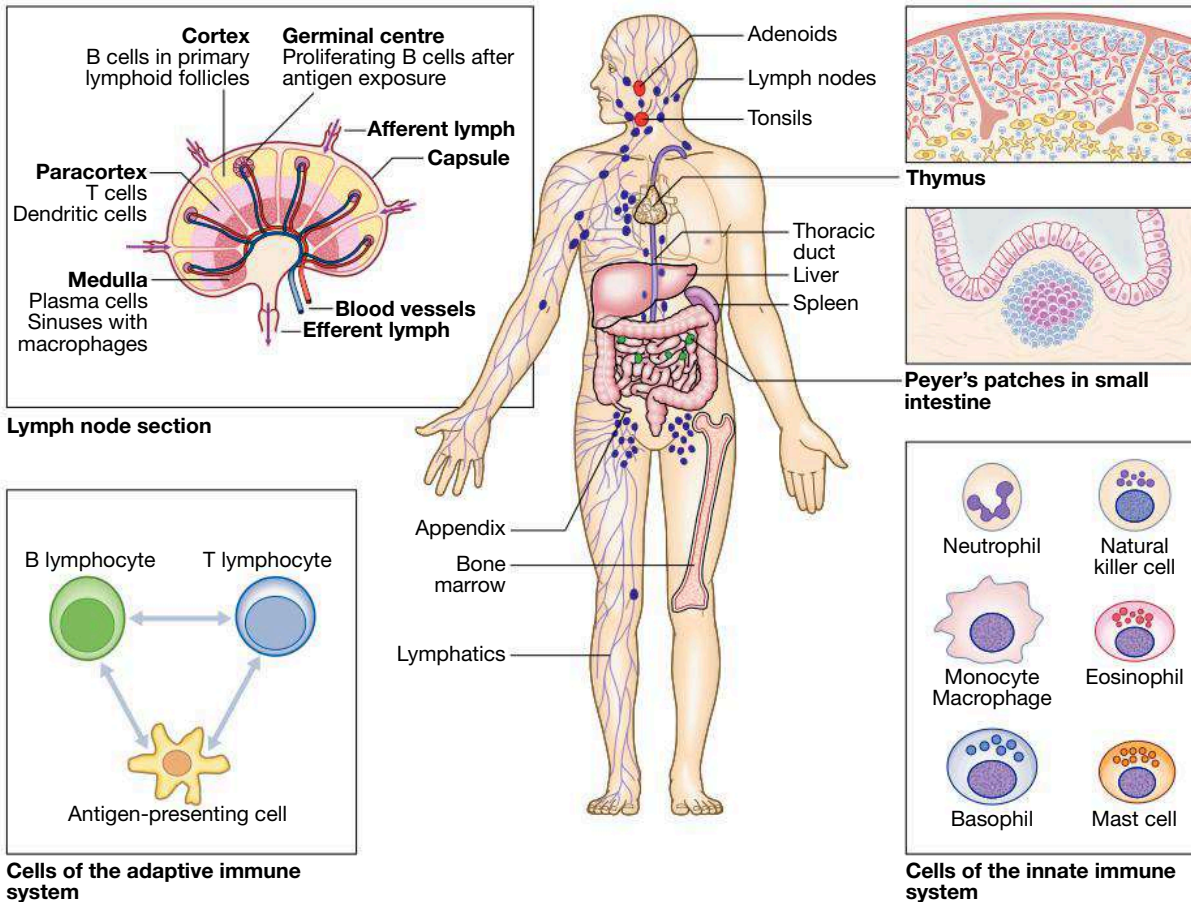

Fig. 4.1 Anatomy of the immune system.

The microbiome, which is made up of endogenous commensal bacteria, provides an additional constitutive defence against infection. Approximately  $10^{14}$  bacteria normally reside at epithelial surfaces in symbiosis with the human host. They compete with pathogenic microorganisms for scarce resources, including space and nutrients, and produce fatty acids and bactericidins that inhibit the growth of many pathogens. In addition, recent research has demonstrated that commensal bacteria help to shape the immune response by inducing specific regulatory T cells within the intestine. Eradication of the normal flora with broad-spectrum antibiotics commonly results in opportunistic infection by organisms such as *Clostridioides difficile*, which rapidly colonise an undefended ecological niche.

These constitutive barriers are highly effective, but if external defences are breached by a wound or pathogenic organism, the specific soluble proteins and cells of the innate immune system are activated.

## Phagocytes

Phagocytes ('eating cells') are specialised cells that ingest and kill microorganisms, scavenge cellular and infectious debris, and produce inflammatory molecules that regulate other components of the immune system. They include neutrophils, monocytes and macrophages, and are particularly important for defence against bacterial and fungal infections. Phagocytes express a wide range of surface receptors, including pattern recognition receptors (PRRs), which recognise pathogen-associated molecular patterns (PAMPs) on invading microorganisms, allowing their identification. The PRRs include Toll-like receptors, nucleotide oligomerisation domain (NOD) protein-like receptors and mannose receptors, whereas the PAMPs they recognise are molecular motifs not present on mammalian cells, including bacterial cell wall components, bacterial DNA and viral double-stranded RNA. Interaction between the PRRs and their PAMPs leads to activation of nuclear factor kappa B (NF $\kappa$ B), which stimulates expression of pro-inflammatory genes, and of nucleotide-binding

oligomerisation domain (NOD)-like receptor proteins (NLRP), which form complexes with other intracellular proteins to form the inflammasome (Fig. 4.2). The inflammasome results in activation of interleukin-1 beta (IL-1 $\beta$ ), which is excreted extracellularly and plays a key pathogenic role in familial fever syndromes (p. 76) and acute gout (Ch. 26). While phagocytes can recognise microorganisms through PRRs alone, engulfment of microorganisms is greatly enhanced by opsonisation. Opsonins include acute phase proteins produced by the liver, such as C-reactive protein and complement component C3b. Antibodies generated by the adaptive immune system also act as opsonins. They bind both to the pathogen and to phagocyte receptors, acting as a bridge between the two to facilitate phagocytosis (see Fig. 4.2). This is followed by intracellular pathogen destruction and downstream activation of pro-inflammatory genes, resulting in the generation of pro-inflammatory cytokines as discussed below.

## Neutrophils

Neutrophils, also known as polymorphonuclear leucocytes, are derived from the bone marrow and circulate freely in the blood. They are short-lived cells with a half-life of 6 hours, and are produced at the rate of  $10^{11}$  cells daily. Their functions are to kill microorganisms, to facilitate rapid transit of cells through tissues and to amplify the immune response non-specifically. These functions are mediated by enzymes contained in granules, which also provide an intracellular milieu for the killing and degradation of microorganisms.

Two main types of granule are recognised: primary or azurophil granules, and the more numerous secondary or specific granules. Primary granules contain myeloperoxidase and other enzymes important for intracellular killing and digestion of ingested microbes. Secondary granules are smaller and contain lysozyme, collagenase and lactoferrin, which can be released into the extracellular space. Enzyme production is increased in response to infection, which is reflected by more intense granule staining on microscopy, known as 'toxic granulation'.

**Fig. 4.2 Phagocytosis and opsonisation.** Phagocytosis of microbes can be augmented by several opsonins, such as C-reactive protein, antibodies and complement fragments like C3b, which enhance the ability of phagocytic cells to engulf microorganisms and destroy them. Phagocytes also recognise components of microbes, such as lipopolysaccharide, peptidoglycans, DNA and RNA, collectively known as pathogen-associated molecular patterns (PAMPs). These activate pattern recognition receptors (PRRs), such as Toll-like receptors and nucleotide oligomerisation domain (NOD)-like receptors, which promote inflammatory gene expression through the nuclear factor kappa B (NF $\kappa$ B) pathway. Uric acid and other crystals can also promote inflammation through the NOD pathway. (IL = interleukin; LPS = lipopolysaccharide; NLRP = nucleotide-binding oligomerisation domain (NOD)-like receptor proteins)

Changes in damaged or infected cells trigger local production of inflammatory molecules and cytokines. These cytokines stimulate the production and maturation of neutrophils in the bone marrow, and their release into the circulation. Neutrophils are recruited to specific sites of infection by chemotactic agents, such as interleukin 8 (IL-8), and by activation of local endothelium. Up-regulation of cellular adhesion molecules on neutrophils and the endothelium also facilitates neutrophil migration. The transit of neutrophils through the blood stream is responsible for the rise in neutrophil count that occurs in early infection. Once present within infected tissue, activated neutrophils seek out and engulf invading microorganisms. These are initially enclosed within membrane-bound vesicles, which fuse with cytoplasmic granules to form the phagolysosome. Within this protected compartment, killing of the organism occurs through a combination of oxidative and non-oxidative killing. Oxidative killing, also known as the respiratory burst, is mediated by the nicotinamide adenine dinucleotide phosphate (NADPH)–oxidase enzyme complex, which converts oxygen into reactive oxygen species such as hydrogen peroxide and superoxide that are lethal to microorganisms. The myeloperoxidase enzyme within neutrophils produces hypochlorous acid, which is a powerful oxidant and antimicrobial agent. Non-oxidative (oxygen-independent) killing occurs through the release of bactericidal enzymes into the phagolysosome. Each enzyme has a distinct antimicrobial spectrum, providing broad coverage against bacteria and fungi.

An additional, recently identified form of neutrophil-mediated killing is neutrophil extracellular trap (NET) formation. Activated neutrophils can release chromatin with granule proteins such as elastase to form an extracellular matrix that binds to microbial proteins. This can immobilise or kill microorganisms without requiring phagocytosis. The process of phagocytosis and NET formation (NETosis) depletes neutrophil glycogen reserves and is followed by neutrophil death. As the cells die, their contents are released and lysosomal enzymes degrade collagen and other components of the interstitium, causing liquefaction of closely adjacent tissue. The accumulation of dead and dying neutrophils results in the formation of pus, which, if extensive, may lead to abscess formation.

### Monocytes and macrophages

Monocytes are the precursors of tissue macrophages. They are produced in the bone marrow and enter the circulation, where they constitute about 5% of leucocytes. From the blood stream they migrate to peripheral tissues, where they differentiate into tissue macrophages and reside for long periods. Specialised populations of tissue macrophages include Kupffer cells in the liver, alveolar macrophages in the lung, mesangial cells in the kidney, and microglial cells in the brain. Macrophages, like neutrophils, are capable of phagocytosis and killing of microorganisms but also play an important role in the amplification and regulation of the inflammatory response (Box 4.1). They are particularly important in tissue surveillance and constantly survey their immediate surroundings for signs of tissue damage or invading organisms.

### Dendritic cells

Dendritic cells are specialised antigen-presenting cells that are present in tissues in contact with the external environment, such as the skin and mucosal membranes. They can also be found in an immature state in the blood. They sample the environment for foreign particles and, once activated, carry microbial antigens to regional lymph nodes, where they interact with T cells and B cells to initiate and shape the adaptive immune response.

### Cytokines

Cytokines are signalling proteins produced by cells of the immune system and a variety of other cell types. More than 100 have been identified. Cytokines have complex and overlapping roles in cellular communication and regulation of the immune response. Subtle differences in cytokine production, particularly at the initiation of an immune response, can have a major impact on outcome. Cytokines bind to specific receptors on

## 4.1 Functions of macrophages

### Amplification of the inflammatory response

- Stimulate the acute phase response (through production of IL-1 and IL-6)
- Activate vascular endothelium (IL-1, TNF- $\alpha$ )
- Stimulate neutrophil maturation and chemotaxis (IL-1, IL-8)
- Stimulate monocyte chemotaxis

### Killing of microorganisms

- Phagocytosis
- Microbial killing through oxidative and non-oxidative mechanisms

### Clearance, resolution and repair

- Scavenging of necrotic and apoptotic cells
- Clearance of toxins and other inorganic debris
- Tissue remodelling (elastase, collagenase, matrix proteins)
- Down-regulation of inflammatory cytokines
- Wound healing and scar formation (IL-1, platelet-derived growth factor, fibroblast growth factor)

### Link between innate and adaptive immune systems

- Activate T cells by presenting antigen in a recognisable form
- T cell-derived cytokines increase phagocytosis and microbicidal activity of macrophages in a positive feedback loop

(IL = interleukin; TNF = tumour necrosis factor)

target cells and activate downstream intracellular signalling pathways, ultimately leading to changes in gene transcription and cellular function. Two important signalling pathways are illustrated in Figure 4.3. The nuclear factor kappa B (NF $\kappa$ B) pathway is activated by tumour necrosis factor (TNF), by other members of the TNF superfamily such as receptor activator of nuclear kappa B ligand (RANKL), and by the Toll-like receptors and NOD-like receptors (see Fig. 4.2). In the case of TNF superfamily members, receptor binding causes the inhibitor of kappa B kinase (IKK) complex of three proteins to be recruited to the receptor by binding TNF receptor-associated proteins (TRAF). This activates IKK, which in turn leads to phosphorylation of the inhibitor of nuclear factor kappa B protein (I $\kappa$ B), causing it to be degraded by the proteasome, allowing NF $\kappa$ B to translocate to the nucleus and activate gene transcription. The Janus kinase/signal transducers and activators of transcription (JAK-STAT) pathway is involved in transducing signals downstream of many cytokine receptors, including those for IL-2, IL-6 and interferon-gamma (IFN- $\gamma$ ). On receptor binding, JAK proteins are recruited to the intracellular portion of the receptor and are phosphorylated. These in turn phosphorylate STAT proteins, which translocate to the nucleus and activate gene transcription, altering cellular function. The function and disease associations of several important cytokines are shown in Box 4.2. Cytokine inhibitors are now routinely used in the treatment of autoimmune diseases, most of which are monoclonal antibodies to cytokines or their receptors. In addition, small-molecule inhibitors have been developed that inhibit the intracellular signalling pathways used by cytokines. These include the Janus kinase inhibitors tofacitinib, baricitinib and upadacitinib and filgotinib which are used in the treatment of various inflammatory rheumatic diseases and inflammatory bowel disease, and the tyrosine kinase inhibitor imatinib, which is used in chronic myeloid leukaemia and other haematological malignancies.

### Integrins

Integrins are transmembrane proteins that play important roles in cell–cell and cell–matrix interactions. They are expressed on lymphocytes as well as a variety of other cell types and mediate attachment of cells to the endothelium and the extracellular matrix, affecting cell migration and signal transduction. Their role in autoimmune disease has been extensively studied and therapeutic agents are now being developed which modify binding of integrins to their targets. For example, natalizumab is a monoclonal antibody which targets the  $\alpha$ 4 integrin which is expressed on lymphocytes. Natalizumab prevents  $\alpha$ 4 $\beta$ 1 integrin binding to VCAM-1 and the  $\alpha$ 4 $\beta$ 7 integrin binding to MAdCAM-1 resulting in an anti-inflammatory

**Fig. 4.3 Cytokines signalling pathways and the immune response.** Cytokines regulate the immune response through binding to specific receptors that activate a variety of intracellular signalling pathways, two of which are shown. Members of the tumour necrosis factor (TNF) superfamily and the Toll-like receptors and NOD-like receptors (see Fig. 4.2) signal through the nuclear factor kappa B (NFκB) pathway. Several other cytokines, including IL-2, IL-6 and interferons, employ the Janus kinase/signal transducer and activator of transcription (JAK-STAT) pathway to regulate cellular function (see text for more details). (IFN, interferon; IκB = inhibitor of kappa B; IKK = I kappa B kinase; IL = interleukin; P = phosphorylation of the signalling protein; TRAF = tumour necrosis factor receptor-associated factor)

effect. It is an effective treatment for multiple sclerosis, which works by preventing immune cells from entering the central nervous system by interfering with lymphocyte binding the  $\alpha 4\beta 1$  integrin. This treatment is not without risk, however, since there are reports of progressive multifocal leucoencephalopathy (PML) in MS treated patients, as a result of JC virus infection of the central nervous system. Similarly, vedolizumab, a monoclonal antibody directed against the  $\alpha 4/\beta 7$  integrin, is an effective treatment for Crohn's disease and ulcerative colitis which works selectively by preventing lymphocytes entering gut endothelium by inhibiting the interaction with MADCAM-1.

## Complement

The complement system comprises a group of more than 20 tightly regulated, functionally linked proteins that act to promote inflammation and eliminate invading pathogens. Complement proteins are produced in the liver and are present in inactive form in the circulation. When the complement system is activated, it sets in motion a rapidly amplified biological cascade analogous to the coagulation cascade.

There are three mechanisms by which the complement cascade can be activated (Fig. 4.4):

- The *alternate pathway* is triggered directly by binding of C3 to bacterial cell-wall components, such as lipopolysaccharide of Gram-negative bacteria and teichoic acid of Gram-positive bacteria.
- The *classical pathway* is initiated when two or more IgM or IgG antibody molecules bind to antigen. The associated conformational change exposes binding sites on the antibodies for the first protein in the classical pathway, C1, which is a multiheaded molecule that can bind up to six antibody molecules. Once two or more 'heads' of a C1 molecule are bound to antibody, the classical cascade is triggered. An important inhibitor of the classical pathway is C1 inhibitor (C1inh), as illustrated in Figure 4.4.
- The *lectin pathway* is activated when mannose-binding lectin interacts with microbial cell surface carbohydrates. This directly stimulates the classical pathway at the level of C4, bypassing the need for immune complex formation.

**Fig. 4.4 The complement pathway.** The classical pathway is activated by binding of antigen–antibody complexes to C1 but is blocked by C1 inhibitor (C1inh), whereas mannose-binding lectins, which are macromolecules that bind to carbohydrates on the surface of various microorganisms, activate the pathway by binding C4. Bacteria can directly activate the pathway through C3, which plays a pivotal role in complement activation through all three pathways.

Activation of complement by any of these pathways results in activation of C3. This in turn activates the final common pathway, in which the complement proteins C5–C9 assemble to form the membrane attack complex (MAC). This can puncture the cell wall, leading to osmotic lysis of target cells.

4.2 Important cytokines in the regulation of the immune response			
Cytokine	Source	Actions	Biologic therapies
<b>Interferon-alpha (IFN-<math>\alpha</math>)</b>	T cells and macrophages	Antiviral activity Activates NK cells, CD8 <sup>+</sup> T cells and macrophages	Recombinant IFN- $\alpha$ used in hepatitis C and some malignancies
<b>Interferon-gamma (IFN-<math>\gamma</math>)</b>	T cells and NK cells	Increases antimicrobial activity of macrophages Regulates cytokine production by T cells and macrophages	Interferon- $\gamma$ used in chronic granulomatous disease
<b>Tumour necrosis factor alpha (TNF-<math>\alpha</math>)</b>	Macrophages, NK cells and others, including T cells	Pro-inflammatory Increases expression of other cytokines and adhesion molecules Causes apoptosis of some target cells Directly cytotoxic	TNF- $\alpha$ inhibitors used in rheumatoid arthritis, inflammatory bowel disease, psoriasis and many other inflammatory conditions
<b>Interleukin-1 (IL-1)</b>	Macrophages and neutrophils	Stimulates neutrophil recruitment, fever, and T-cell and macrophage activation as part of the inflammatory response	IL-1 inhibitors used in systemic juvenile rheumatoid arthritis, periodic fever syndromes and acute gout
<b>Interleukin-2 (IL-2)</b>	CD4 <sup>+</sup> T cells	Stimulates proliferation and differentiation of antigen-specific T lymphocytes	IL-2 inhibitors used in the treatment of transplant rejection
<b>Interleukin-4 (IL-4)</b>	CD4 <sup>+</sup> T cells	Stimulates maturation of B and T cells, and production of IgE antibody	Antibodies to IL-4 receptor used in severe atopic dermatitis
<b>Interleukin-5 (IL-5)</b>	CD4 <sup>+</sup> T cells, mast cells, eosinophils and basophils	Growth and differentiation factor for B cells and eosinophils	Antibodies to IL-5 or the IL-5 receptor used in treatment refractory eosinophilic asthma and more recently anti-IL-5 antibodies used in eosinophilic vasculitis
<b>Interleukin-6 (IL-6)</b>	Monocytes and macrophages	Stimulates neutrophil recruitment, fever, and T-cell and macrophage activation as part of the inflammatory response, stimulates maturation of B cells into plasma cells	Antibodies to IL-6 receptor used in rheumatoid arthritis and giant cell arteritis
<b>Interleukin-12 (IL-12)</b>	Monocytes and macrophages	Stimulates IFN- $\gamma$ and TNF- $\alpha$ release by T cells Activates NK cells	Antibody to p40 subunit of IL-12 used in psoriasis and psoriatic arthritis
<b>Interleukin-17 (IL-17)</b>	Th17 cells (T helper), NK cells, NK-T cells	Pro-inflammatory cytokine Involved in mucosal immunity and control of extracellular pathogens, synergy with IL-1 and TNF	Antibody to IL-17 used in psoriasis, psoriatic arthritis and ankylosing spondylitis
<b>Interleukin-22 (IL-22)</b>	Th17 cells	Induction of epithelial cell proliferation and antimicrobial proteins in keratinocytes	
<b>Interleukin-23 (IL-23)</b>	Activated macrophages and dendritic cells in peripheral tissues	Pro-inflammatory cytokine, proliferation of Th17 T cells with induction of IL-17	Antibody to IL-23 used in psoriasis, psoriatic arthritis and inflammatory bowel disease

(IgE = immunoglobulin E; NK = natural killer)

This step is particularly important in the defence against encapsulated bacteria such as *Neisseria* spp. and *Haemophilus influenzae*.

Complement fragments generated by activation of the cascade can also act as opsonins, rendering microorganisms more susceptible to phagocytosis by macrophages and neutrophils (see Fig. 4.2). In addition, they are chemotactic agents, promoting leucocyte trafficking to sites of inflammation. Some fragments act as anaphylotoxins, binding to complement receptors on mast cells and triggering release of histamine, which increases vascular permeability. The products of complement activation also help to target immune complexes to antigen-presenting cells, providing a link between the innate and the adaptive immune systems. Finally, activated complement products dissolve the immune complexes that triggered the cascade, minimising bystander damage to surrounding tissues.

There are a number of control proteins within the complement system that prevent activation on host cells, thereby preventing host cell damage, some of which are membrane bound, others soluble, such as C1 inhibitor. Factor H is an important example in control of the alternate pathway, CD59 and decay accelerating factor (DAF) are important in the terminal complement pathway. Deficiencies in factor H can lead to atypical haemolytic uraemic syndrome and failure of binding of CD59 and DAF due to deficiency in the anchoring glycosylphosphatidylinositol on red blood cells can lead to paroxysmal nocturnal haemoglobinuria as a result of complement-mediated haemolysis. A monoclonal antibody directed against the central complement molecule C5, eculizumab, has been developed for therapeutic use in these conditions. Invasive infection, including meningococcal sepsis, has been reported with eculizumab therapy, highlighting the importance of the complement system in preventing such infections.

## Mast cells and basophils

Mast cells and basophils are bone marrow-derived cells that play a central role in allergic disorders. Mast cells reside predominantly in tissues exposed to the external environment, such as the skin and gut, while basophils circulate in peripheral blood and are recruited into tissues in response to inflammation. Both contain large cytoplasmic granules that enclose vasoactive substances such as histamine (see Fig. 4.14). Mast cells and basophils express IgE receptors on their cell surface, which bind IgE antibody. On encounter with specific antigen, the cell is triggered to release histamine and other mediators present within the granules and to synthesise additional mediators, including leukotrienes, prostaglandins and cytokines. An inflammatory cascade is initiated that increases local blood flow and vascular permeability, stimulates smooth muscle contraction and increases secretion at mucosal surfaces.

## Natural killer cells

Natural killer (NK) cells are large granular lymphocytes that play a major role in defence against tumours and viruses. They exhibit features of both the adaptive and the innate immune systems in that they are morphologically similar to lymphocytes and recognise similar ligands, but they are not antigen-specific and cannot generate immunological memory. NK cells express a variety of cell surface receptors, some of which are stimulatory and others inhibitory. The effects of inhibitory receptors normally predominate. These recognise human leucocyte antigen (HLA) molecules that are expressed on normal nucleated cells, preventing NK cell-mediated attack, whereas the stimulatory receptors recognise molecules that are expressed primarily when cells are damaged. This allows NK cells to remain tolerant to healthy cells but not to damaged ones. When cells become infected by viruses or undergo malignant change, expression of HLA class I molecules on the cell surface can be down-regulated. This is an important mechanism by which these cells then evade adaptive T-lymphocyte responses. In this circumstance, however, NK cell defences becomes important, as down-regulation of HLA class I abrogates the inhibitory signals that normally prevent NK activation. The net result is NK attack on the abnormal target cell. NK cells can also be activated by binding of antigen-antibody complexes to surface receptors. This physically links the NK cell to its target in a manner analogous to opsonisation and is known as antibody-dependent cellular cytotoxicity (ADCC).

Activated NK cells can kill their targets in various ways. They secrete pore-forming proteins such as perforin into the membrane of the target cell, and proteolytic enzymes called granzymes into the target cell, which cause apoptosis. In addition, NK cells produce a variety of cytokines such as TNF- $\alpha$  and IFN- $\gamma$ , which have direct antiviral and anti-tumour effects.

## The adaptive immune system

If the innate immune system fails to provide effective protection against an invading pathogen, the adaptive immune system is mobilised (see Fig. 4.1). This has three key characteristics:

- It has exquisite specificity and can discriminate between very small differences in molecular structure.
- It is highly adaptive and can respond to an almost unlimited number of molecules.
- It possesses immunological memory, and changes consequent to initial activation by an antigen allow a more effective immune response on subsequent encounters.

There are two major arms of the adaptive immune response. Humoral immunity involves the production of antibodies by B lymphocytes, and cellular immunity involves the activation of T lymphocytes, which synthesise and release cytokines that affect other cells, as well as directly killing target cells. These interact closely with each other and with the components of the innate immune system to maximise effectiveness of the immune response.

## Lymphoid organs

The primary lymphoid organs are involved in lymphocyte development. They include the bone marrow, where T and B lymphocytes differentiate from haematopoietic stem cells and where B lymphocytes also mature, and the thymus, the site of T-cell maturation (see Fig. 4.1). After maturation, lymphocytes migrate to the secondary lymphoid organs. These include the spleen, lymph nodes and mucosa-associated lymphoid tissue. These trap and concentrate foreign substances and are the major sites of interaction between naïve lymphocytes and microorganisms.

### The thymus

The thymus is a bi-lobed structure in the anterior mediastinum, and is organised into cortical and medullary areas. The cortex is densely populated with immature T cells, which migrate to the medulla to undergo selection and maturation. The thymus is most active in the fetal and neonatal period, and involutes after puberty. Failure of thymic development is associated with profound T-cell immune deficiency but surgical removal of the thymus in childhood (usually during major cardiac surgery) is not associated with significant immune dysfunction.

### The spleen

The spleen is the largest of the secondary lymphoid organs. It is highly effective at filtering blood and is an important site of phagocytosis of senescent erythrocytes, bacteria, immune complexes and other debris, and of antibody synthesis. It is important for defence against encapsulated bacteria, and asplenic individuals are at risk of overwhelming *Streptococcus pneumoniae* and *H. influenzae* infection (see Box 4.5).

### Lymph nodes

These are positioned to maximise exposure to lymph draining from sites of external contact, and are highly organised (see Fig. 4.1).

- The *cortex* contains primary lymphoid follicles, which are the site of B-lymphocyte interactions. When B cells encounter antigen, they undergo intense proliferation, forming germinal centres.
- The *paracortex* is rich in T lymphocytes and dendritic cells.
- The *medulla* is the major site of antibody-secreting plasma cells.
- Within the medulla there are many *sinuses*, which contain large numbers of macrophages.

### Mucosa-associated lymphoid tissue

Mucosa-associated lymphoid tissue (MALT) consists of diffusely distributed lymphoid cells and follicles present along mucosal surfaces. It has a similar function to the more organised, encapsulated lymph nodes. They include the tonsils, adenoids and Peyer's patches in the small intestine.

### Lymphatics

Lymphoid tissue is connected by a network of lymphatics, with three major functions: lymphatics provide access to lymph nodes, return interstitial fluid to the venous system and transport fat from the small intestine to the blood stream (see Fig. 19.12). The lymphatics begin as blind-ending capillaries, which come together to form lymphatic ducts, entering and leaving regional lymph nodes as afferent and efferent ducts, respectively. They eventually coalesce and drain into the thoracic duct and left subclavian vein. Lymphatics may be either deep or superficial, and follow the distribution of major blood vessels.

## Humoral immunity

Humoral immunity is mediated by B lymphocytes, which differentiate from haematopoietic stem cells in the bone marrow. Their major functions are to produce antibody and interact with T cells, but they are also involved in antigen presentation. Mature B lymphocytes can be found in the bone marrow, lymphoid tissue, spleen and, to a lesser extent, the blood stream. They express a unique immunoglobulin receptor on their cell surface, the B-cell receptor, which binds to soluble antigen targets (Fig. 4.5).

Encounters with antigen usually occur within lymph nodes. If provided with appropriate cytokines and other signals from nearby T lymphocytes, antigen-specific B cells respond by rapidly proliferating in a process known as clonal expansion (see Fig. 4.5). This is accompanied by a highly complex series of genetic rearrangements known as somatic hypermutation, which generates B-cell populations that express receptors with greater affinity for antigen than the original. These cells differentiate into either long-lived memory cells, which reside in the lymph nodes, or plasma cells, which produce antibody. Memory cells allow production of a more rapid and more effective response on subsequent exposure to that pathogen.

## Immunoglobulins

Immunoglobulins (Ig) play a central role in humoral immunity. They are soluble proteins produced by plasma cells and are made up of two heavy and two light chains (Fig. 4.6). The heavy chain determines the antibody class or isotype, such as IgG, IgA, IgM, IgE or IgD. Subclasses of IgG and IgA also occur. The antigen is recognised by the antigen-binding regions ( $F_{ab}$ ) of both heavy and light chains, while the consequences of antibody binding are determined by the constant region of the heavy chain ( $F_c$ ) (Box 4.3). Antibodies have several functions. They facilitate phagocytosis by acting as opsonins (see Fig. 4.2) and facilitate cell killing by cytotoxic cells, particularly NK cells by antibody-dependent cellular cytotoxicity. Binding of antibodies to antigen can trigger activation of the classical complement pathway (see Fig. 4.4). In addition, antibodies can directly neutralise the biological activity of their antigen target. This is a particularly important feature of IgA antibodies, which act predominantly at mucosal surfaces.

The humoral immune response is characterised by immunological memory, in which the antibody response to successive exposures to an antigen is qualitatively and quantitatively improved from the first exposure. When a previously unstimulated or 'naïve' B lymphocyte is activated by antigen, the first antibody to be produced is IgM, which appears in the serum after 5–10 days. Depending on additional stimuli provided by T lymphocytes, other antibody classes (IgG, IgA and IgE) are produced 1–2 weeks later. If the memory B cell is subsequently re-exposed

**Fig. 4.5 B-cell activation.** Activation of B cells is initiated through binding of an antigen with the immunoglobulin receptor on the cell surface. For activation to proceed, an interaction with T-helper cells is also required, providing additional signals through binding of CD40 ligand (CD40L) to CD40; an interaction between the T-cell receptor (TCR) and processed antigenic peptides presented by human leucocyte antigen (HLA) molecules on the B-cell surface; and cytokines released by the T-helper cells. Fully activated B cells undergo clonal expansion with differentiation towards plasma cells that produce antibody. Following activation, memory cells are generated that allow rapid antibody responses when the same antigen is encountered on a second occasion. (IL = interleukin)

to the same antigen, the lag time between exposure and production of antibody is decreased to 2–3 days, the amount of antibody produced is increased, and the response is dominated by IgG antibodies of high affinity. Furthermore, in contrast to the initial antibody response, secondary antibody responses do not require additional input from T lymphocytes. This allows the rapid generation of highly specific responses on re-exposure to a pathogen and is an important mechanism in vaccine efficacy.

## Cellular immunity

Cellular immunity is mediated by T lymphocytes, which play important roles in defence against viruses, fungi and intracellular bacteria. They also play an important immunoregulatory role, by orchestrating and regulating the responses of other components of the immune system. T-lymphocyte precursors differentiate from haematopoietic stem cells in the bone marrow and are exported to the thymus when they are still immature (see Fig. 4.1). Individual T cells express a unique receptor that is highly specific for a single antigen. Within the thymus T cells undergo a process of stringent selection to ensure that autoreactive cells are destroyed. Mature T lymphocytes leave the thymus and expand to populate other organs of the immune system. It has been estimated that an individual possesses  $10^7$ – $10^9$  T-cell clones, each with a unique T-cell receptor, ensuring at least partial coverage for any antigen encountered.

Unlike B cells, T cells cannot recognise intact protein antigens in their native form. Instead, the protein must be broken down into component peptides by antigen-presenting cells for presentation to T lymphocytes in association with HLA molecules on the antigen-presenting cell surface (Fig. 4.7). This process is known as antigen processing and presentation, and it is the complex of peptide and HLA together that is recognised by individual T cells. The structure of HLA molecules varies widely between individuals. Since each HLA molecule has the capacity to present a subtly different peptide repertoire to T lymphocytes, this ensures enormous diversity in recognition of antigens by the T-cell population. All nucleated cells have the capacity to process and present antigens, but cells with specialised antigen-presenting functions include dendritic cells, macrophages and B lymphocytes. These cells carry additional co-stimulatory molecules, such as CD80 and CD86, providing the necessary 'second signal' for full T-cell activation (Fig. 4.8). Mechanisms also exist to inhibit activation of T-cells. One of the most important is the programmed cell death 1 (PD-1) pathway. The PD1 receptor is expressed on lymphocytes and inhibits lymphocyte activation when bound by its ligand (PDL-1) which is a molecule expressed on antigen-presenting cells, endothelial cells and some tumour cells (Fig. 4.8). Monoclonal antibodies which inhibit this interaction are important treatments for certain types of cancer (see tumour immunology later in this chapter).

T lymphocytes can be divided into two subgroups on the basis of function and recognition of HLA molecules. These are designated CD4<sup>+</sup> and CD8<sup>+</sup> T cells, according to the 'cluster of differentiation' (CD) antigen number of key proteins expressed on their cell surface.

### CD8<sup>+</sup> T lymphocytes

These cells recognise antigenic peptides in association with HLA class I molecules (HLA-A, HLA-B, HLA-C). They kill infected cells directly

**Fig. 4.6 The structure of an immunoglobulin (antibody) molecule.** The variable region is responsible for antigen binding, whereas the constant region can interact with immunoglobulin receptors expressed on immune cells.

### 4.3 Classes and properties of antibody

Antibody	Concentration in adult serum	Complement activation*	Opsonisation	Presence in external secretions	Other properties
IgG	6.0–16.0 g/L	IgG1 +++ IgG2 + IgG3 +++	IgG1 ++ IgG3 ++	++	Four subclasses: IgG1, IgG2, IgG3, IgG4 Distributed equally between blood and extracellular fluid, and transported across placenta IgG2 is particularly important in defence against polysaccharides antigens
IgA	1.5–4.0 g/L	–	–	++++	Two subclasses: IgA1, IgA2 Highly effective at neutralising toxins Particularly important at mucosal surfaces
IgM	0.5–2.0 g/L	++++	–	+	Highly effective at agglutinating pathogens
IgE	0.003–0.04 g/L	–	–	–	Majority of IgE is bound to mast cells, basophils and eosinophils Important in allergic disease and defence against parasite infection
IgD	Not detected	–	–	–	Function in B-cell development

\*Activation of the classical pathway, also called 'complement fixation'.  
(IgG = immunoglobulin)

**Fig. 4.7 Antigen presentation.** For T-cell activation, antigen has to be processed via antigen-presenting cells (APC). Pathogens, bearing pathogen-associated molecular patterns (PAMPs) on their surface, are recognised by pattern recognition receptors (PRRs) on the APC. Following endocytosis, the pathogen is broken down intracellularly. Antigenic peptides are then loaded onto human leucocyte antigens (HLA), also known as major histocompatibility complexes (MHC), and presented at the APC surface. The combination of peptide and HLA is then recognised by the T-cell receptor (TCR). For T-cell activation, a second, co-stimulatory signal is required through binding of CD80 or CD86 on the APC to CD28 on the T cell (see also Fig. 4.8). (CD28 and CD80/86 = co-stimulatory molecules; IL = interleukin)

through the production of pore-forming molecules such as perforin and release of digesting enzymes triggering apoptosis of the target cell, and are particularly important in defence against viral infection.

#### CD4<sup>+</sup> T lymphocytes

These cells recognise peptides presented on HLA class II molecules (HLA-DR, HLA-DP and HLA-DQ) and have mainly immunoregulatory functions. They produce cytokines and provide co-stimulatory signals that support the activation of CD8<sup>+</sup> T lymphocytes and assist the production of mature antibody by B cells. In addition, their close interaction

with phagocytes determines cytokine production by both cell types. CD4<sup>+</sup> lymphocytes can be further subdivided into subsets on the basis of the cytokines they produce:

- Th1 (T-helper) cells typically produce IL-2, IFN- $\gamma$  and TNF- $\alpha$ , and support the development of delayed-type hypersensitivity responses.
- Th2 cells typically produce IL-4, IL-5, IL-10 and IL-13, and promote allergic responses.
- T-regulatory cells (T-regs) are a further subset of specialised CD4<sup>+</sup> lymphocytes that are important in actively suppressing activation of other cells and preventing autoimmune disease. They produce cytokines such as TGF- $\beta$  and IL-10.
- Th17 cells are pro-inflammatory cells defined by their production of IL-17. They are related to regulatory T cells. Th17 cells have a key role in defence against extracellular bacteria and fungi. They also have a role in the development of autoimmune disease.

T-cell activation is regulated by a balance between co-stimulatory molecules, the second signal required for activation, and inhibitory molecules that down-regulate T-cell activity. One such inhibitory molecule, CTLA4, has been harnessed therapeutically in the form of abatacept, which is a fusion protein comprised of the Fc fragment of immunoglobulin linked to CTLA4. This is used to inhibit T-cell activation in rheumatoid arthritis and solid organ transplantation.

## The inflammatory response

Inflammation is the response of tissues to injury or infection, and is necessary for normal repair and healing. This section focuses on the general principles of the inflammatory response and its multisystem manifestations. The role of inflammation in specific diseases is discussed in many other chapters of this book.

### Acute inflammation

Acute inflammation is the result of rapid and complex interplay between the cells and soluble molecules of the innate immune system. The classical external signs include heat, redness, pain and swelling (Fig. 4.9). The inflammatory process is initiated by local tissue injury or infection. Damaged epithelial cells produce cytokines and antimicrobial peptides, causing early infiltration of phagocytic cells. Production of leukotrienes,

**Fig. 4.8 T-cell activation.** Activation of T cells is initiated when an antigenic peptide bound to a human leucocyte antigen (HLA) molecule on antigen-presenting cells interacts with the T-cell receptor expressed by T lymphocytes. Additional signals are required for T-cell activation, however. These include binding of the co-stimulatory molecules CD80 and CD86 with CD28 on the T cell, and interleukin 2 (IL-2), which is produced in an autocrine manner by T cells that are undergoing activation. Other molecules are present that can inhibit T-cell activation, however, including cytotoxic T-lymphocyte-associated protein 4 (CTLA4), which competes with CD28 for binding to CD80 and CD86; and PD-1, which, by binding PD-L1, is also inhibitory. Following activation, T cells proliferate and, depending on their subtype, have various functions with distinct patterns of cytokine production, as indicated. Memory cells are also generated that can mount a rapid immune response on encountering the same antigen. (IL- $\gamma$  = interferon-gamma; IL = interleukin; PD-1 = programmed cell death 1; PD-L1 = programmed death ligand 1; TCR = T-cell receptor; TGF- $\beta$  = transforming growth factor beta; TNF- $\alpha$  = tumour necrosis factor alpha)

prostaglandins, histamine, kinins, anaphylotoxins and inducible nitric oxide synthase also occurs within inflamed tissue. These mediators cause vasodilatation and increased vascular permeability, causing trafficking of fluid and cells into the affected tissue. In addition, pro-inflammatory cytokines, such as IL-1, TNF- $\alpha$  and IL-6 produced at the site of injury, are released systemically and act on the hypothalamus to cause fever, and on the liver to stimulate production of acute phase proteins.

### The acute phase response

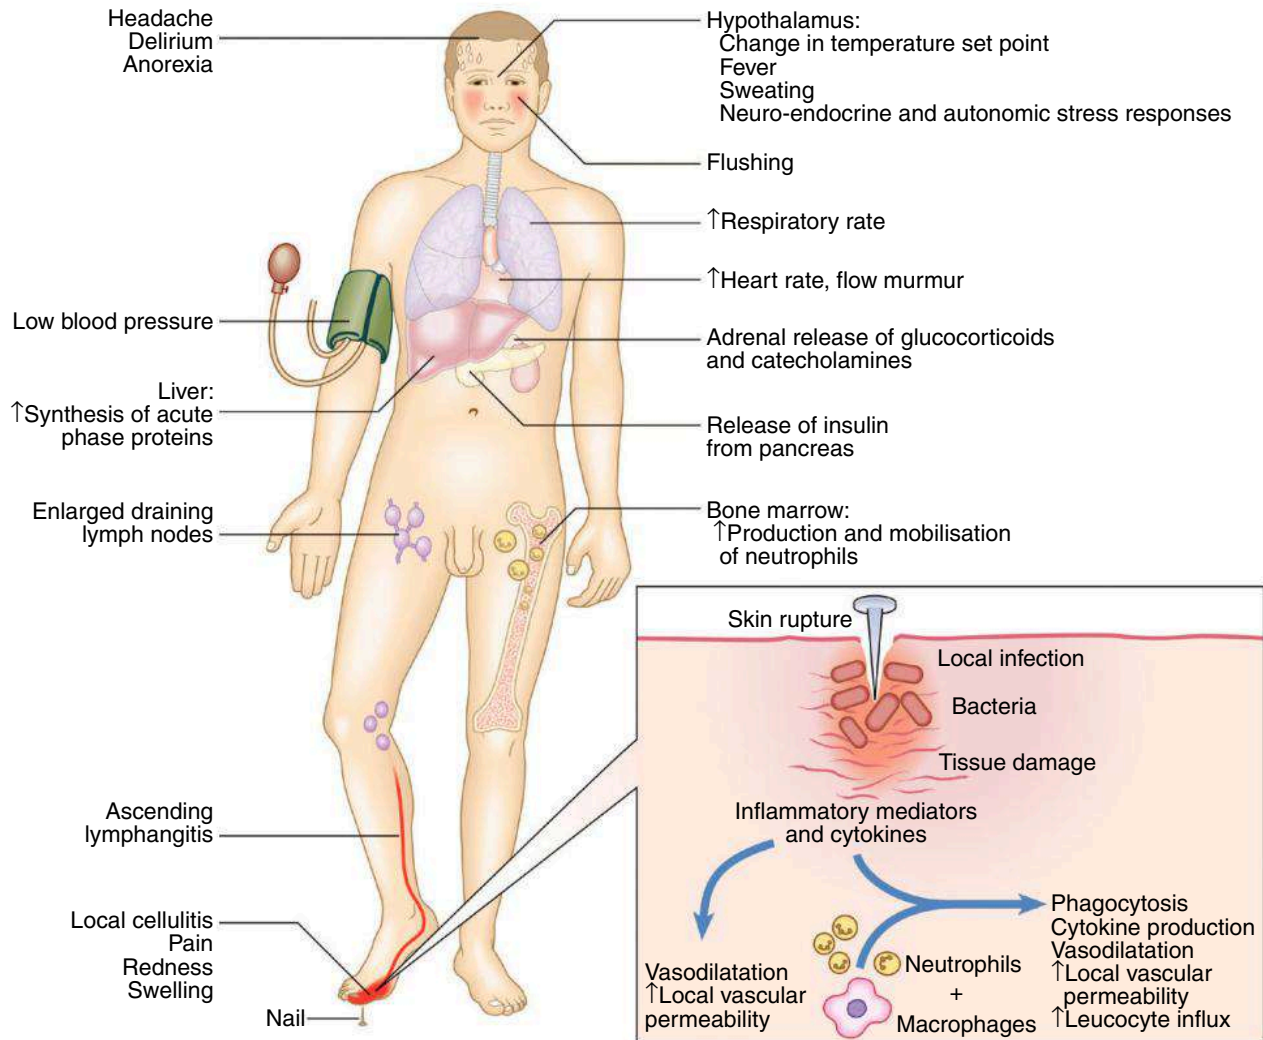

The acute phase response refers to the production of a variety of proteins by the liver in response to inflammatory stimuli. These proteins have a wide range of activities. Circulating levels of C-reactive protein (CRP) and serum amyloid A may be increased 100- to 1000-fold, contributing to host defence and stimulating repair and regeneration. Fibrinogen plays an essential role in wound healing, and  $\alpha_1$ -antitrypsin and  $\alpha_1$ -antichymotrypsin control the pro-inflammatory cascade by neutralising the enzymes produced by activated neutrophils, preventing widespread tissue destruction. In addition, antioxidants such as haptoglobin and manganese superoxide dismutase scavenge for oxygen free radicals, while increased levels of iron-binding proteins such as ferritin and lactoferrin decrease the iron available for uptake by bacteria. Immunoglobulins are not acute phase proteins but are often increased in chronic inflammation.

### Septic shock

Septic shock is the clinical manifestation of overwhelming inflammation. It is characterised by excessive production of pro-inflammatory cytokines by macrophages, causing hypotension, hypovolaemia and tissue oedema. In addition, uncontrolled neutrophil activation causes release of proteases and oxygen free radicals within blood vessels, damaging the vascular endothelium and further increasing capillary permeability. Direct activation of the coagulation pathway combines with endothelial cell disruption to form clots within the damaged vessels. The clinical consequences include cardiovascular collapse, acute respiratory distress syndrome, disseminated intravascular coagulation, multi-organ failure and often death. Septic shock most frequently results from infection with Gram-negative bacteria, because lipopolysaccharide produced by these organisms is particularly effective at activating the inflammatory cascade. Early recognition and appropriate early intervention can improve patient outcome. More details on the diagnosis and management of septic shock are provided in Chapter 9.

### Resolution of inflammation

Resolution of an inflammatory response is crucial for normal healing. This involves active down-modulation of inflammatory stimuli and repair

**Fig. 4.9 Clinical features of acute inflammation.** In this example, the response is to a penetrating injury and infection of the foot.

of bystander damage to local tissues. Extravasated neutrophils undergo apoptosis and are phagocytosed by macrophages, along with the remains of microorganisms. Macrophages also synthesise collagenase and elastase, which break down local connective tissue and aid in the removal of debris. Normal tissue homeostasis is also associated with reversion of parenchymal cells to a non-inflammatory phenotype. Macrophage-derived cytokines, including transforming growth factor-beta (TGF- $\beta$ ) and platelet-derived growth factor, stimulate fibroblasts and promote the synthesis of new collagen, while angiogenic factors stimulate new vessel formation.

## Chronic inflammation

In most instances, the development of an active immune response results in clearance and control of the inflammatory stimulus and resolution of tissue damage. Failure of this process may result in chronic inflammation, with significant associated bystander damage, known as hypersensitivity responses. Persistence of microorganisms can result in ongoing accumulation of neutrophils, macrophages and activated T lymphocytes within the lesion. If this is associated with local deposition of fibrous tissue, a granuloma may form. Granulomas are characteristic of tuberculosis and leprosy (Hansen's disease), in which the microorganism is protected by a robust cell wall that shields it from killing, despite phagocytosis.

## Laboratory features of inflammation

Inflammation is associated with changes in many laboratory investigations. Leucocytosis is common, and reflects the transit of activated neutrophils and monocytes to the site of infection. The platelet count may also be increased. The most widely used laboratory measure of acute inflammation is CRP. Circulating levels of many other acute phase reactants, including fibrinogen, ferritin and complement components, are also increased in response to acute inflammation, while albumin levels are reduced. Chronic inflammation is frequently associated with a normocytic normochromic anaemia.

## C-reactive protein

C-reactive protein (CRP) is an acute phase reactant synthesised by the liver, which opsonises invading pathogens. Circulating concentrations of CRP increase within 6 hours of the start of an inflammatory stimulus. Serum concentrations of CRP provide a direct biomarker of acute inflammation and, because the serum half-life of CRP is 18 hours, levels fall promptly once the inflammatory stimulus is removed. Sequential measurements are useful in monitoring disease activity (Box 4.4). For reasons that remain unclear, some diseases are associated with only minor elevations of CRP despite

unequivocal evidence of active inflammation. These include systemic lupus erythematosus (SLE), systemic sclerosis, ulcerative colitis and leukaemia. An important practical point is that if the CRP is raised in these conditions, it suggests intercurrent infection rather than disease activity. Since the CRP is a more sensitive early indicator of the acute phase response, it is generally used in preference to the erythrocyte sedimentation rate (ESR). If both ESR and CRP are used, any discrepancy should be resolved by assessing the individual determinants of the ESR, which are discussed below.

### Erythrocyte sedimentation rate

The ESR is an indirect measure of inflammation. It measures how fast erythrocytes fall through plasma, which is determined by the composition of plasma proteins and the morphology of circulating erythrocytes. These factors govern the propensity of red cells to aggregate, the major determinant of the ESR. Erythrocytes are inherently negatively charged, which prevents them from clumping together in the blood stream. Since plasma proteins such as fibrinogen and immunoglobulins are positively charged, increased concentrations of these proteins neutralise an increase in plasma protein concentrations neutralises the negative charge of erythrocytes, overcoming their inherent repulsive forces and causing them to aggregate, resulting in rouleaux formation. Rouleaux have a higher mass-to-surface area ratio than single red cells, and therefore sediment faster. The most common reason for an increased ESR is an acute phase response, which causes an increase in the concentration of acute phase proteins, including CRP. However, other conditions that do not affect acute phase proteins may alter the composition and concentration of other plasma proteins (see Box 4.4). For example, immunoglobulins comprise a significant proportion of plasma proteins but do not participate in the acute phase response. Thus any condition that causes an increase in serum immunoglobulins will increase the ESR without a corresponding increase in CRP. In addition, abnormal red cell morphology can make rouleaux formation impossible. For these reasons, an inappropriately low ESR occurs in spherocytosis and sickle-cell anaemia.

### Plasma viscosity

Plasma viscosity is another surrogate measure of plasma protein concentration. Like the ESR, it is affected by the concentration of large plasma proteins, including fibrinogen and immunoglobulins. It is not affected by

properties of erythrocytes and is generally considered to be more reliable than the ESR as a marker of inflammation.

## Presenting problems in immune disorders

### Recurrent infections

Infections can occur in otherwise healthy individuals but recurrent infection raises suspicion of an immune deficiency. Depending on the component of the immune system affected, the infections may involve bacteria, viruses, fungi or protozoa, as summarised in Box 4.5. T-cell deficiencies can involve pathogens from all groups.

#### Aetiology

Infections secondary to immune deficiency occur because of defects in the number or function of phagocytes, B cells, T cells or complement, as described later in this chapter.

#### Clinical assessment

Clinical features that may indicate immune deficiency are listed in Box 4.6. Frequent or severe infections, or ones caused by unusual organisms or at unusual sites, are typical of immune deficiency.

#### Investigations

Initial investigations should include full blood count and white cell differential, CRP, renal and liver function tests, urine dipstick, serum immunoglobulins with protein electrophoresis, and HIV testing. Additional microbiological tests, virology and imaging are required to identify the causal organism and localise the site of infection, as outlined in Box 4.7. If primary immune deficiency is suspected on the basis of initial investigations, more specialised tests should be considered, as summarised in Box 4.8.

#### Management

If an immune deficiency is suspected but has not yet been formally characterised, patients should not receive live vaccines because of the risk of vaccine-induced disease. Further management depends on the underlying cause and details are provided later.

### 4.4 Conditions commonly associated with abnormal C-reactive protein (CRP) and/or erythrocyte sedimentation rate (ESR)

Condition	Consequence	Effect on CRP <sup>1</sup>	Effect on ESR <sup>2</sup>
Acute bacterial, fungal or viral infection	Stimulates acute phase response	Increased (range 50–150 mg/L; in severe infections may be > 300 mg/L)	Increased
Necrotising bacterial infection	Stimulates profound acute inflammatory response	Greatly increased (may be > 300 mg/L)	Increased
Chronic bacterial or fungal infection Localised abscess, bacterial endocarditis or tuberculosis	Stimulates acute and chronic inflammatory response with polyclonal increase in immunoglobulins, as well as increased acute phase proteins	Increased (range 50–150 mg/L)	Increased disproportionately to CRP
Acute inflammatory diseases Crohn's disease, polymyalgia rheumatica, inflammatory arthritis	Stimulates acute phase response	Increased (range 50–150 mg/L)	Increased
Systemic lupus erythematosus, Sjögren syndrome, ulcerative colitis	Chronic inflammatory response	Normal	Increased
Multiple myeloma	Monoclonal increase in serum immunoglobulin without acute inflammation	Normal	Increased
Pregnancy, old age, end-stage renal disease	Increased fibrinogen	Normal	Moderately increased

<sup>1</sup>Reference range <5 mg/L. <sup>2</sup>Reference range: adult males <10 mm/hr, adult females <3–15 mm/hr.

## 4.6 Warning signs of primary immune deficiency\*

In children	In adults
≥ 4 new ear infections within 1 year	≥ 2 new ear infections within 1 year
≥ 2 serious sinus infections within 1 year	≥ 2 new sinus infections within 1 year, in the absence of allergy
≥ 2 months on antibiotics with little effect	Recurrent viral infections
≥ 2 pneumonias within 1 year	≥ 1 pneumonia per year for more than 1 year
Failure of an infant to gain weight or grow normally	Chronic diarrhoea with weight loss
Recurrent deep skin or organ abscesses	Recurrent deep skin or organ abscesses
Persistent thrush in mouth or elsewhere on skin after infancy	Persistent thrush or fungal infection on skin or elsewhere
Need for intravenous antibiotics to clear infections	Recurrent need for intravenous antibiotics to clear infections
≥ 2 deep-seated infections such as sepsis, meningitis or cellulitis	Infection with atypical mycobacteria
A family history of primary immune deficiency	A family history of primary immune deficiency

\*The presence of two or more of the listed features may indicate the presence of an underlying primary immunodeficiency.  
©Jeffrey Modell Foundation.

## Intermittent fever

Intermittent fever has a wide differential diagnosis, including recurrent infection, malignancy and certain rheumatic disorders, such as Still's disease, vasculitis and SLE but a familial fever syndrome is a potential cause.

### Aetiology

Familial fever syndromes are genetic disorders caused by mutations in genes responsible for regulating the inflammatory response. The

## 4.7 Initial investigations in suspected immune deficiency

Test	Value	Comment
<b>Full blood count</b>	Full white cell differential	May define pathway for further investigation
<b>Acute phase reactants</b>	Help determine presence of active infection	
<b>Serum immunoglobulins</b>	Detection of antibody deficiency	
<b>Serum protein electrophoresis</b>	Detection of paraprotein	May be the cause of immune paresis; paraprotein should be excluded prior to diagnosis of primary antibody deficiency
<b>Serum free light chains/Bence Jones proteins</b>	Detection of paraprotein	
<b>Human immunodeficiency virus (HIV) test</b>	To exclude HIV as cause of secondary immune deficiency	
<b>Imaging according to history and examination findings</b>	Detection of active infection/end-organ damage	To support treatment decisions

symptoms are caused by activation of intracellular signalling pathways involved in the regulation of inflammation, with over-production of pro-inflammatory cytokines such as IL-1.

### Clinical assessment

A full clinical history and physical examination should be performed, paying attention to the patient's ethnic background and any family history of a similar disorder. If this assessment shows no evidence of underlying infection, malignancy or a rheumatic disorder and there is a positive

#### 4.8 Specialist investigations in suspected immune deficiency

Test	Value	Comment
<b>Complement (C3/C4/CH50/AP50)</b>	Investigation of recurrent pyogenic bacterial infection	Inherited complement deficiency likely to give low/absent results on functional assays
<b>Test vaccination</b>	Determination of functional humoral immune response	Helpful in patients with borderline low or normal immunoglobulins but confirmed recurrent infection
<b>Neutrophil function</b>	Investigation of recurrent invasive bacterial and fungal infection, especially with catalase-positive organisms	Respiratory burst low/absent in chronic granulomatous disease
	Investigation of leucocyte adhesion deficiency	Leucocytosis with absent CD11a, b, c expression
<b>Lymphocyte immunophenotyping (by flow cytometry)</b>	Determination of specific lymphocyte subsets, T cell, B cell, NK cell	May define specific primary immune deficiency, e.g. absent B cells in X-linked agammaglobulinaemia
<b>Lymphocyte proliferation</b>	Determination of lymphocyte proliferation in response to mitogenic stimulation	Poor responses seen in certain T-cell immune deficiencies
<b>Cytokine production</b>	To determine T-cell immune function in response to antigen stimulation; limited availability, not routine	Can be helpful, for example, in investigation of atypical mycobacterial infection
<b>Genetic testing</b>	Under specialist supervision when specific primary immune deficiency suspected	May confirm genetic cause, with implications for family members and future antenatal testing

(NK = natural killer)

family history and early age at onset, then the likelihood of a familial fever syndrome is increased.

#### Investigations

Blood should be taken for a full blood count, measurement of ESR and CRP, and assessment of renal and liver function. Serum ferritin should be checked, as very high levels support the diagnosis of Still's disease. Blood and urine cultures should also be performed, along with an auto-immune screen that includes measurement of antinuclear antibodies and consideration of antineutrophil cytoplasmic antibodies to check for evidence of SLE or vasculitis, respectively. Imaging may be required to exclude occult infection. If these investigations provide no evidence of infection or another cause, then genetic analysis should be considered to confirm the diagnosis of a familial fever syndrome. Negative genetic testing does not, however, entirely exclude a periodic fever syndrome.

#### Management

Symptomatic management with non-steroidal anti-inflammatory drugs (NSAIDs) should be initiated, pending the results of investigations. If the response to NSAIDs is inadequate, glucocorticoids can be tried, provided that infection has been excluded. If a familial fever syndrome is confirmed, then definitive therapy should be initiated, depending on the underlying diagnosis, as discussed later in this chapter (p. 76).

#### Anaphylaxis

Anaphylaxis is a potentially life-threatening, systemic allergic reaction characterised by circulatory collapse, bronchospasm, laryngeal stridor, often associated with angioedema, and urticaria. The risk of death is increased in patients with pre-existing asthma, particularly if this is poorly controlled, and in situations where treatment with adrenaline (epinephrine) is delayed. Further details are provided in the 'Presenting problems in acute medicine' section in Chapter 9.

### Immune deficiency

The consequences of immune deficiency include recurrent infection, autoimmunity as a result of immune dysregulation, and increased susceptibility to malignancy, especially malignancy driven by viral infections such as Epstein-Barr virus. Immune deficiency may arise through

intrinsic defects in immune function but is much more commonly due to secondary causes, including infection, drug therapy, malignancy and ageing. This section gives an overview of primary immune deficiencies. More than a hundred such deficiencies have been described, most of which are genetically determined and present in childhood or adolescence. The presentation of immune deficiency depends on the component of the immune system that is defective (see Box 4.5). There is considerable overlap and redundancy in the immune network, however, and some diseases do not fall easily into this classification.

#### Primary phagocyte deficiencies

Primary phagocyte deficiencies typically present with recurrent bacterial and fungal infections, which may involve unusual sites. Affected patients require aggressive management of infections, including intravenous antibiotics and surgical drainage of abscesses, and long-term prophylaxis with antibacterial and antifungal agents. The most important examples are illustrated in Figure 4.10 and discussed below.

##### Chronic granulomatous disease

This is caused by mutations in genes that encode NADPH oxidase enzymes, which results in failure of oxidative killing. The defect leads to susceptibility to catalase-positive organisms such as *Staphylococcus aureus*, *Burkholderia cenocepacia* and *Aspergillus*. Intracellular killing of mycobacteria in macrophages is also impaired. Infections most commonly involve the lungs, lymph nodes, soft tissues, bone, skin and urinary tract, and are characterised histologically by granuloma formation. Most cases are X-linked

##### Leucocyte adhesion deficiencies

These very rare disorders of phagocyte migration occur because of failure to express adhesion molecules on the surface of leucocytes, resulting in their inability to exit the blood stream. The most common cause is loss-of-function mutations affecting the *ITGB2* gene, which encodes the integrin  $\beta$ -2 chain, a component of the adhesion molecule LFA1. They are characterised by recurrent bacterial infections but sites of infection lack evidence of neutrophil infiltration, such as pus formation. Peripheral blood neutrophil counts may be very high during acute infection because of the failure of mobilised neutrophils to exit blood vessels. Specialised tests show reduced or absent expression of adhesion molecules on neutrophils.

**Fig. 4.10 Normal phagocyte function and mechanisms of primary phagocyte deficiency.** Under normal circumstances, neutrophils traverse the endothelium to enter tissues by the cell surface molecule lymphocyte function-associated antigen 1 (LFA1), which binds to intercellular adhesion molecule 1 (ICAM1) on endothelium. In order for macrophages to engulf and kill microorganisms, they need to be activated by cytokines and also require nicotinamide adenine dinucleotide phosphate (NADPH) oxidase to generate free radicals. Primary phagocyte deficiencies can occur as the result of leucocytes being unable to traverse endothelium due to defects in LFA1, because of mutations in cytokines or their receptors, or because of defects in NADPH oxidase. (IFN- $\gamma$  = interferon-gamma; IL = interleukin)

### Defects in cytokines and cytokine receptors

Mutations of the genes encoding cytokines such as IFN- $\gamma$ , IL-12, IL-23 or their receptors result in failure of intracellular killing by macrophages, and affected individuals are particularly susceptible to mycobacterial infections.

## Complement pathway deficiencies

Loss-of-function mutations have been identified in almost all the complement pathway proteins (see Fig. 4.4). While most complement deficiencies are rare, mannose-binding lectin deficiency is common and affects about 5% of the northern European population, many of whom are asymptomatic (see below).

### Clinical features

Patients with deficiency in complement proteins can present in different ways. In some cases, the presenting feature is recurrent infection with encapsulated bacteria, particularly *Neisseria* spp., reflecting the importance of the membrane attack complex in defence against these organisms. However, genetic deficiencies of the classical complement pathway (C1, C2 and C4) also present with an increased risk of autoimmune disease, particularly SLE. Individuals with mannose-binding lectin deficiency have an increased incidence of bacterial infections if subjected to an additional cause of immune compromise, such as premature birth or chemotherapy. The significance of this condition has been debated, however, since population studies have shown no overall increase in infectious disease or mortality in patients with this disorder. Deficiency of the regulatory protein C1 inhibitor is not associated with recurrent infection but causes recurrent angioedema.

### Investigations

Screening for complement deficiencies usually involves specialised functional tests of complement-mediated haemolysis. These are known as the CH50 (classical haemolytic pathway 50) and AP50 (alternative pathway 50) tests. If abnormal, haemolytic tests are followed by measurement of individual complement components.

### Management

Patients with complement deficiencies should be vaccinated with meningococcal, pneumococcal and *H. influenzae* B vaccines to boost their adaptive immune responses. Lifelong prophylactic penicillin to prevent meningococcal infection is recommended, as is early access to acute medical assessment in the event of infection. Patients should also carry a MedicAlert or similar. At-risk family members should be screened for complement deficiencies with functional complement assays. The management of C1 esterase deficiency is discussed elsewhere.

## Primary antibody deficiencies

Primary antibody deficiencies occur as the result of abnormalities in B-cell function, as summarised in Figure 4.11. They are characterised by recurrent bacterial infections, particularly of the respiratory and gastrointestinal tract. The most common causative organisms are encapsulated bacteria such as *Streptococcus pneumoniae* and *H. influenzae*. These disorders usually present in infancy, when the protective benefit of placental transfer of maternal immunoglobulin has waned. The most important causes are discussed in more detail below.

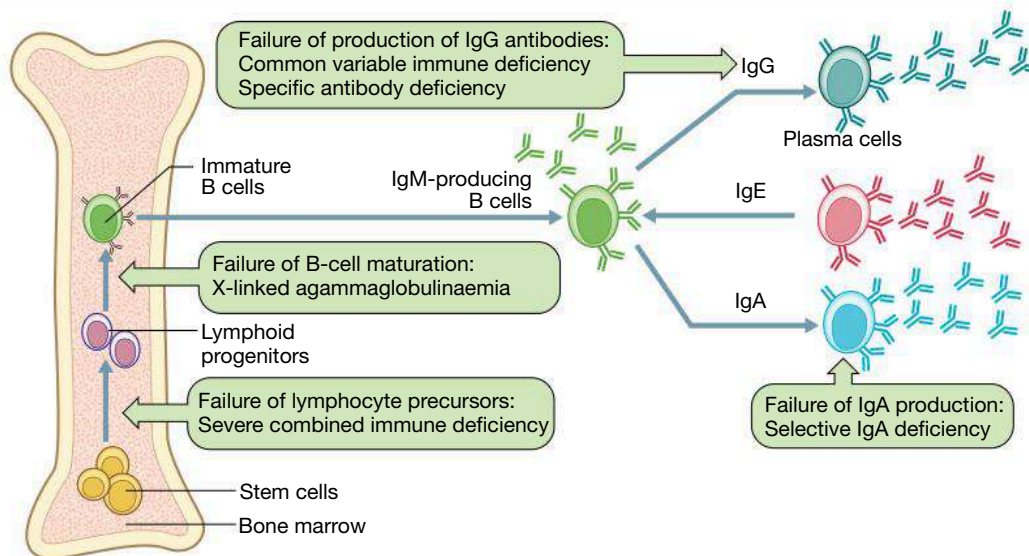

Fig. 4.11 B lymphocytes and primary antibody deficiencies (green boxes). (Ig = immunoglobulin)

	Serum immunoglobulin (Ig) concentrations				Circulating lymphocyte numbers		Test immunisation
	IgM	IgG	IgA	IgE	B cells	T cells	
<b>Selective IgA deficiency</b>	Normal	Often elevated	Absent	Normal	Normal	Normal	Not applicable*
<b>Common variable immune deficiency</b>	Normal or low	Low	Low or absent	Low or absent	Variable	Variable	No antibody response
<b>Specific antibody deficiency</b>	Normal	Normal	Normal	Normal	Normal	Normal	No antibody response to polysaccharide antigens

\*Test immunisation is not usually performed in IgA deficiency but some patients may have impaired responses.

### X-linked agammaglobulinaemia

This rare X-linked disorder is caused by mutations in the *BTK* gene, which encodes Bruton tyrosine kinase, a signalling protein that is required for B-cell development. Affected males present with severe bacterial infections during infancy. There is a marked reduction in B-cell numbers and immunoglobulin levels are low or undetectable. Management is with immunoglobulin replacement therapy and antibiotics to treat infections.

### Selective IgA deficiency

This is the most common primary antibody deficiency, affecting 1:600 northern Europeans. Although IgA deficiency is usually asymptomatic with no clinical sequelae, about 30% of individuals experience recurrent mild respiratory and gastrointestinal infections. The diagnosis can be confirmed by measurement of IgA levels, which are low or undetectable (< 0.05 g/L). In some patients, there is a compensatory increase in serum IgG levels. Specific treatment is generally not required.

### Common variable immune deficiency

Common variable immune deficiency (CVID) is characterised by low serum IgG levels and failure to make antibody responses to exogenous pathogens. It is a heterogeneous adult-onset primary immune deficiency, the underlying cause is unknown in most cases, although genetic mutations have been identified in a minority of patients. The

presentation is with recurrent infections, and bronchiectasis is a recognised complication. Paradoxically, antibody-mediated autoimmune diseases, such as idiopathic thrombocytopenic purpura and autoimmune haemolytic anaemia, are common in CVID. It is also associated with an increased risk of malignancy, particularly lymphoproliferative disease.

### Specific antibody deficiency

This is a poorly characterised condition resulting in defective antibody responses to polysaccharide antigens. Some patients are also deficient in the antibody subclasses IgG2 and IgG4, and this condition was previously called IgG subclass deficiency. There is overlap between specific antibody deficiency, IgA deficiency and CVID, and some patients may progress to a more global antibody deficiency over time.

### Investigations

Serum immunoglobulins (Box 4.9) should be measured in conjunction with protein and urine electrophoresis to exclude secondary causes of hypogammaglobulinaemia, and B- and T-lymphocyte subsets should be measured. Specific antibody responses to known pathogens should be assessed by measuring IgG antibodies against tetanus, *H. influenzae* and *Strep. pneumoniae* (most patients will have been exposed to these antigens through infection or immunisation). If specific antibody levels are low, immunisation with the appropriate killed vaccine should

be followed by repeat antibody measurement 6–8 weeks later; failure to mount a response indicates a significant defect in antibody production. These functional tests have generally superseded IgG subclass quantitation.

### Management

The mainstay of treatment in most patients with antibody deficiency is immunoglobulin replacement therapy. Human normal immunoglobulin (Box 4.10) is derived from plasma from hundreds of donors and contains IgG antibodies to a wide variety of common organisms. Replacement immunoglobulin may be administered either intravenously or subcutaneously, with the aim of maintaining trough IgG levels (the IgG level just prior to an infusion) within the normal range. This has been shown to minimise progression of end-organ damage and improve clinical outcome. Patients with antibody deficiencies also require aggressive treatment of infections when they occur; prophylactic antibiotics may be indicated. Treatment may be self-administered and is life-long. Benefits of immunisation are limited because of the defect in IgG antibody production, but patients may derive some T cell benefit from vaccination. As with all primary immune deficiencies, live vaccines should be avoided.

## Primary T-lymphocyte deficiencies

These are a group of diseases characterised by recurrent viral, protozoal and fungal infections (see Box 4.5). Many T-cell deficiencies are also associated with defective antibody production because of the importance of T cells in providing help for B cells. These disorders generally present in childhood. Several causes of T-cell deficiency are recognised. These are summarised in Figure 4.12 and discussed in more detail below.

### DiGeorge syndrome

This results from failure of development of the third and fourth pharyngeal pouches, and is usually caused by a deletion of chromosome 22q11. The immune deficiency is accounted for by failure of thymic development; however, the immune deficiency can be very heterogeneous. Affected patients can have very low numbers of circulating T cells despite normal development in the bone marrow. It is associated with multiple developmental anomalies, including congenital heart disease, hypoparathyroidism, tracheo-oesophageal fistulae, cleft lip and palate.

## 4.10 Types of immunoglobulin preparations for therapeutic use

### Normal human Immunoglobulin

Derived from multiple plasma donors and provides passive immunity to those unable to produce immunoglobulin, be that as a result of primary or secondary antibody deficiency. Immunoglobulin replacement therapy provides short-term protection, lasting for the duration of the passively transferred antibodies, IgG having a half-life of approximately 21 days. Treatment is therefore required on an ongoing basis

### Hyperimmune globulin

Concentrated antibody products, initially derived from animal sources (diphtheria and tetanus anti-toxins), but more recently of human origin, developed for the prevention of a number of infectious diseases, including rabies as post-exposure treatment, hepatitis B and varicella zoster virus as post-exposure prophylaxis and cytomegalovirus as prophylaxis in patients on immune suppressive therapy, particularly transplant recipients

### Convalescent plasma

Convalescent plasma derived from individual donors with high antibody levels against certain pathogens following recovery from natural infection, recently under investigation for the treatment of epidemic/pandemic infection, such as Ebola virus infection and more recently COVID-19, where clinical trials of ABO-compatible convalescent plasma for severe COVID-19 pneumonia have to date proved disappointing, possibly as a result of such intervention being given too late in the course of infection.

## Bare lymphocyte syndromes

These very rare disorders are caused by mutations in a variety of genes that regulate expression of HLA molecules or their transport to the cell surface. If HLA class I molecules are affected, CD8<sup>+</sup> lymphocytes fail to develop normally, while absent expression of HLA class II molecules affects CD4<sup>+</sup> lymphocyte maturation. In addition to recurrent infections, failure to express HLA class I is associated with systemic vasculitis caused by uncontrolled activation of NK cells.

## Severe combined immune deficiency

Severe combined immune deficiency (SCID) results from mutations in a number of genes that regulate lymphocyte development, with failure of T-cell maturation, with or without accompanying B- and NK-cell maturation. The most common cause is X-linked SCID, resulting from loss-of-function mutations in the interleukin-2 receptor gamma (*IL2RG*) gene. The gene product is a component of several interleukin receptors, including those for IL-2, IL-7 and IL-15, which are absolutely required for T-cell and NK development. This results in T-cell-negative, NK-cell-negative, B-cell-positive SCID. Another cause is deficiency of the enzyme adenosine deaminase (ADA), which causes lymphocyte death due to accumulation of toxic purine metabolites intracellularly, resulting in T-cell-negative, B-cell-negative and NK-cell-negative SCID.

The absence of an effective adaptive immune response causes recurrent bacterial, fungal and viral infections soon after birth. Stem cell transplantation (SCT) is the treatment option of first choice. Gene therapy has been approved for treatment of ADA deficiency when there is no suitable donor for SCT, has been used successfully in X-linked SCID and is under investigation for a number of other causes of SCID.

## Investigations

The principal tests for T-lymphocyte deficiencies are a total lymphocyte count and quantitation of individual lymphocyte subpopulations. Serum immunoglobulins should also be measured. Second-line, functional tests of T-cell activation and proliferation may be indicated. Patients in whom T-lymphocyte deficiencies are suspected should be tested for HIV infection. Genetic testing to identify the underlying cause is usually undertaken following specialist referral.

## Management

Patients with T-cell deficiencies should be considered for anti-*Pneumocystis* and antifungal prophylaxis, and require aggressive management of infections when they occur. Immunoglobulin replacement is indicated for associated defective antibody production. Stem cell transplantation or gene therapy may be appropriate in some disorders. Where a family history is known and antenatal testing confirms a specific defect, stem cell therapy prior to recurrent invasive infection can improve outcome.

## Autoimmune lymphoproliferative syndrome

This rare disorder is caused by failure of normal lymphocyte apoptosis, most commonly due to mutations in the *FAS* gene, which encodes Fas, a signalling protein that regulates programmed cell death in lymphocytes. This results in massive accumulation of autoreactive T cells, which cause autoimmune-mediated anaemia, thrombocytopenia and neutropenia. Other features include lymphadenopathy, splenomegaly and a variety of other autoimmune diseases. Susceptibility to infection is increased because of the neutropenia.

## Secondary immune deficiencies

Secondary immune deficiencies are much more common than primary immune deficiencies and occur when the immune system is compromised by external factors (Box 4.11). Common causes include infections, such as HIV and measles, and cytotoxic and immunosuppressive drugs, particularly those used in the management of transplantation, autoimmunity and cancer. Physiological immune deficiency occurs at the extremes of

Fig. 4.12 T-lymphocyte function and dysfunction (green boxes). (HLA = human leucocyte antigen)

life; the decline of the immune response in the elderly is known as immune senescence (Box 4.12). Management of secondary immune deficiency is described in the relevant chapters on infectious diseases (Ch. 13), HIV (Ch. 14), haematological disorders (Ch. 25) and oncology (Ch. 7).

## Periodic fever syndromes

These rare disorders are characterised by recurrent episodes of fever and organ inflammation, associated with an elevated acute phase response.

## Familial Mediterranean fever

Familial Mediterranean fever (FMF) is the most common of the familial periodic fevers, predominantly affecting Mediterranean people, including Arabs, Turks, Sephardic Jews and Armenians. It results from mutations of the *MEFV* gene, which encodes a protein called pyrin that regulates neutrophil-mediated inflammation by indirectly suppressing the production of IL-1. FMF is characterised by recurrent painful attacks of fever associated with peritonitis, pleuritis and arthritis, which last for a few hours to 4 days and are associated with markedly increased CRP levels. Symptoms resolve completely between episodes. Most individuals have their first attack before the age of 20. The major complication of FMF is AA amyloidosis (see below). Colchicine significantly reduces the number of febrile episodes in 90% of patients but is ineffective during acute attacks. Anti-cytokine therapy blocking IL-1, for example anakinra or the monoclonal antibody canakinumab, can be effective for patients with colchicine refractory symptoms.

## Mevalonate kinase deficiency

Mevalonate kinase deficiency, previously known as hyper-IgD syndrome, is an autosomal recessive disorder that causes recurrent attacks of fever, abdominal pain, diarrhoea, lymphadenopathy, arthralgia, skin lesions and aphthous ulceration. Most patients are from Western Europe, particularly the Netherlands and northern France. It is caused by loss-of-function mutations in the gene encoding mevalonate kinase, which is involved in the metabolism of cholesterol. It remains unclear why this causes an inflammatory periodic fever. Serum IgD and IgA levels may be persistently elevated, and CRP levels are increased during acute attacks. Standard anti-inflammatory drugs, including colchicine and glucocorticoids, are ineffective in suppressing the attacks but IL-1 inhibitors, such as anakinra, and TNF inhibitors, such as etanercept, may improve symptoms and can induce complete remission in some patients.

## TNF receptor-associated periodic syndrome

TNF receptor-associated periodic syndrome (TRAPS) also known as Hibernian fever, is an autosomal dominant syndrome caused by mutations in the *TNFRSF1A* gene. The presentation is with recurrent attacks of

## 4.12 Immune senescence

- **T-cell responses:** decline, with reduced delayed-type hypersensitivity responses.
- **Antibody production:** decreased for many exogenous antigens. Although autoantibodies are frequently detected, autoimmune disease is less common.
- **Response to vaccination:** reduced; 30% of healthy older people may not develop protective immunity after influenza vaccination.
- **Allergic disorders and transplant rejection:** less common.
- **Susceptibility to infection:** increased; community-acquired pneumonia by threefold and urinary tract infection by 20-fold. Latent infections, including tuberculosis and herpes zoster, may be reactivated.
- **Manifestations of inflammation:** may be absent, with lack of pyrexia or leucocytosis.
- **Secondary immune deficiency:** common.

fever, arthralgia, myalgia, serositis and rashes. Attacks may be prolonged for 1 week or more. During a typical attack, laboratory findings include neutrophilia, increased CRP and elevated IgA levels. The diagnosis can be confirmed by low serum levels of the soluble type 1 TNF receptor and by mutation screening of the *TNFRSF1A* gene. As in FMF, the major complication is amyloidosis, and regular screening for proteinuria is advised. Acute episodes respond to systemic glucocorticoids. Therapy with IL-1 inhibitors, such as anakinra, can be effective in preventing attacks.

### Cryopyrin-associated periodic syndrome (CAPS)

This disorder includes three phenotypes: familial cold auto-inflammatory syndrome, Muckle–Wells syndrome and neonatal-onset multisystem inflammatory disease. CAPS results from gain of function mutation of the *NLRP3* gene coding cryopyrin, which forms part of the inflammasome. Defects lead to overproduction of IL-1, resulting in the inflammatory manifestations. Treatments are now targeted at the IL-1 pathway.

## Amyloidosis

Amyloidosis is the name given to a group of acquired and hereditary disorders characterised by the extracellular deposition of insoluble proteins.

### Pathophysiology

Amyloidosis is caused by deposits consisting of fibrils of the specific protein involved, linked to glycosaminoglycans, proteoglycans and serum amyloid P. Protein accumulation may be localised or systemic, and the clinical manifestations depend on the organ(s) affected. Amyloid diseases are classified by the aetiology and type of protein deposited (Box 4.13).

### Clinical features

The clinical presentation may be with nephrotic syndrome, cardiomyopathy or peripheral neuropathy. Amyloidosis should always be considered as a potential diagnosis in patients with these disorders when the cause is unclear.

### Investigations

The diagnosis is established by biopsy, which may be of an affected organ, rectum or subcutaneous fat. The pathognomonic histological feature is apple-green birefringence of amyloid deposits when stained with Congo red dye and viewed under polarised light. Immunohistochemical staining can identify the type of amyloid fibril present. Quantitative scintigraphy with radiolabelled serum amyloid P is a valuable tool in determining the overall load and distribution of amyloid deposits.

### Management

The aims of treatment are to support the function of affected organs and, in acquired amyloidosis, to prevent further amyloid deposition through treatment of the primary cause. When the latter is possible, regression of existing amyloid deposits may occur.

## 4.13 Causes of amyloidosis

Disorder	Pathological basis	Predisposing conditions	Other features
<b>Acquired systemic amyloidosis</b>			
Reactive (AA) amyloidosis	Increased production of serum amyloid A as part of prolonged or recurrent acute inflammatory response	Chronic infection (tuberculosis, bronchiectasis, chronic abscess, osteomyelitis) Chronic inflammatory diseases (untreated rheumatoid arthritis, familial Mediterranean fever)	90% of patients present with non-selective proteinuria or nephrotic syndrome
Light chain amyloidosis (AL)	Increased production of monoclonal light chain	Monoclonal gammopathies, including myeloma, benign gammopathies and plasmacytoma	Restrictive cardiomyopathy, peripheral and autonomic neuropathy, carpal tunnel syndrome, proteinuria, spontaneous purpura, amyloid nodules and plaques Macroglossia occurs rarely but is pathognomonic Prognosis is poor
Dialysis-associated (A $\beta$ <sub>2</sub> M) amyloidosis	Accumulation of circulating $\beta$ <sub>2</sub> -microglobulin due to failure of renal catabolism in kidney failure	Renal dialysis	Carpal tunnel syndrome, chronic arthropathy and pathological fractures secondary to amyloid bone cyst formation Manifestations occur 5–10 years after the start of dialysis
Senile systemic amyloidosis	Normal transthyretin protein deposited in tissues	Age > 70 years	Feature of normal ageing (affects > 90% of 90-year-olds) Usually asymptomatic
<b>Hereditary systemic amyloidosis</b>			
> 20 forms of hereditary systemic amyloidosis	Production of protein with an abnormal structure that predisposes to amyloid fibril formation. Most commonly due to mutations in <i>transthyretin</i> gene	Autosomal dominant inheritance	Peripheral and autonomic neuropathy, cardiomyopathy Renal involvement unusual 10% of gene carriers are asymptomatic throughout life

## Autoimmune disease

Autoimmunity can be defined as the presence of immune responses against self-tissue. This may be a harmless phenomenon, identified only by the presence of low-titre autoantibodies or autoreactive T cells. However, if these responses cause significant organ damage, autoimmune diseases occur. These are a major cause of chronic morbidity and disability, affecting up to 1 in 30 adults at some point during life.

### Pathophysiology

Autoimmune diseases result from the failure of immune tolerance, the process by which the immune system recognises and accepts self-tissue. Central immune tolerance occurs during lymphocyte development, when T and B lymphocytes that recognise self-antigens are eliminated before they develop into fully immunocompetent cells. This process is most active in fetal life but continues throughout life as immature lymphocytes are generated. Some autoreactive cells inevitably evade deletion and escape into the circulation, however, and are controlled through peripheral tolerance mechanisms. Peripheral immune tolerance mechanisms include the suppression of autoreactive cells by regulatory T cells; the generation of functional hyporesponsiveness (anergy) in lymphocytes that encounter antigen in the absence of the co-stimulatory signals that accompany inflammation; and cell death by apoptosis. Autoimmune diseases develop when self-reactive lymphocytes escape from these tolerance mechanisms.

Multiple genetic and environmental factors contribute to the development of autoimmune disease. Autoimmune diseases are much more common in women than in men, for reasons that remain unclear. Many are associated with genetic variations in the HLA loci, reflecting the importance of HLA genes in shaping lymphocyte responses. Other important susceptibility genes include those determining cytokine activity, co-stimulation (the expression of second signals required for full T-cell activation; see Figs. 4.7 and 4.8) and cell death. Many of the same gene variants underlie multiple autoimmune disorders, reflecting their common pathogenesis (Box 4.14). Even though some of these associations are the strongest that have been identified in complex genetic diseases, they have very limited predictive value and are generally not useful in determining management of individual patients. Several environmental factors may be associated with autoimmunity in genetically predisposed individuals, including infection, cigarette smoking and hormone levels. The most widely studied of these is infection, as occurs in acute rheumatic fever following streptococcal infection or reactive arthritis following bacterial infection. Several mechanisms

4.14 Association of specific gene polymorphisms with autoimmune diseases		
Gene	Function	Diseases
<b>HLA complex</b>	Key determinants of antigen presentation to T cells	Most autoimmune diseases
<b>PTPN22</b>	Regulation of T- and B-cell receptor signalling	Rheumatoid arthritis, type 1 diabetes, systemic lupus erythematosus
<b>CTLA4</b>	Important co-stimulatory molecule that transmits inhibitory signals to T cells	Rheumatoid arthritis, type 1 diabetes
<b>IL23R</b>	Cytokine-mediated control of T cells	Inflammatory bowel disease, psoriasis, ankylosing spondylitis
<b>TNFRSF1A</b>	Control of tumour necrosis factor network	Multiple sclerosis
<b>ATG5</b>	Autophagy	Systemic lupus erythematosus

have been invoked to explain the autoimmunity that occurs after an infectious trigger. These include cross-reactivity between proteins expressed by the pathogen and the host (molecular mimicry), such as Guillain-Barré syndrome and *Campylobacter* infection; release of sequestered antigens from tissues that are damaged during infections that are not usually visible to the immune system; and production of inflammatory cytokines that overwhelm the normal control mechanisms that prevent bystander damage. Occasionally, autoimmune disease may be an adverse effect of drug treatment. For example, metabolic products of the anaesthetic agent halothane can bind to liver enzymes, resulting in a structurally novel protein that is recognised as a foreign antigen by the immune system. This can provoke the development of autoantibodies and activated T cells, which can cause hepatic necrosis.

### Clinical features

The clinical presentation of autoimmune disease is highly variable. Autoimmune diseases can be classified by organ involvement or by the predominant mechanism responsible for tissue damage. The Gell and Coombs classification of hypersensitivity is the most widely used, and distinguishes four types of immune response that result in tissue damage (Box 4.15).

- *Type I hypersensitivity* is relevant in allergy but is not associated with autoimmune disease.
- *Type II hypersensitivity* causes injury to a single tissue or organ and is mediated by specific autoantibodies.
- *Type III hypersensitivity* results from deposition of immune complexes, which initiates activation of the classical complement cascade, as well as recruitment and activation of phagocytes and CD4<sup>+</sup> lymphocytes. The site of immune complex deposition is determined by the relative amount of antibody, size of the immune complexes, nature of the

4.15 Gell and Coombs classification of hypersensitivity diseases			
Type	Mechanism	Example of disease in response to exogenous agent	Example of autoimmune disease
<b>Type I</b> Immediate hypersensitivity	IgE-mediated mast cell degranulation	Allergic disease	None described
<b>Type II</b> Antibody-mediated	Binding of cytotoxic IgG or IgM antibodies to antigens on cell surface causes cell killing	ABO blood transfusion reaction Hyperacute transplant rejection	Autoimmune haemolytic anaemia Idiopathic thrombocytopenic purpura Goodpasture's disease
<b>Type III</b> Immune complex-mediated	IgG or IgM antibodies bind soluble antigen to form immune complexes that trigger classical complement pathway activation	Serum sickness Farmer's lung	Systemic lupus erythematosus Cryoglobulinaemia
<b>Type IV</b> Delayed type	Activated T cells, and phagocytes	Acute cellular transplant rejection Nickel hypersensitivity	Type 1 diabetes Hashimoto's thyroiditis

antigen and local haemodynamics. Generalised deposition of immune complexes gives rise to systemic diseases such as SLE.

- *Type IV hypersensitivity* is mediated by activated T cells and macrophages, which together cause tissue damage.

## Investigations

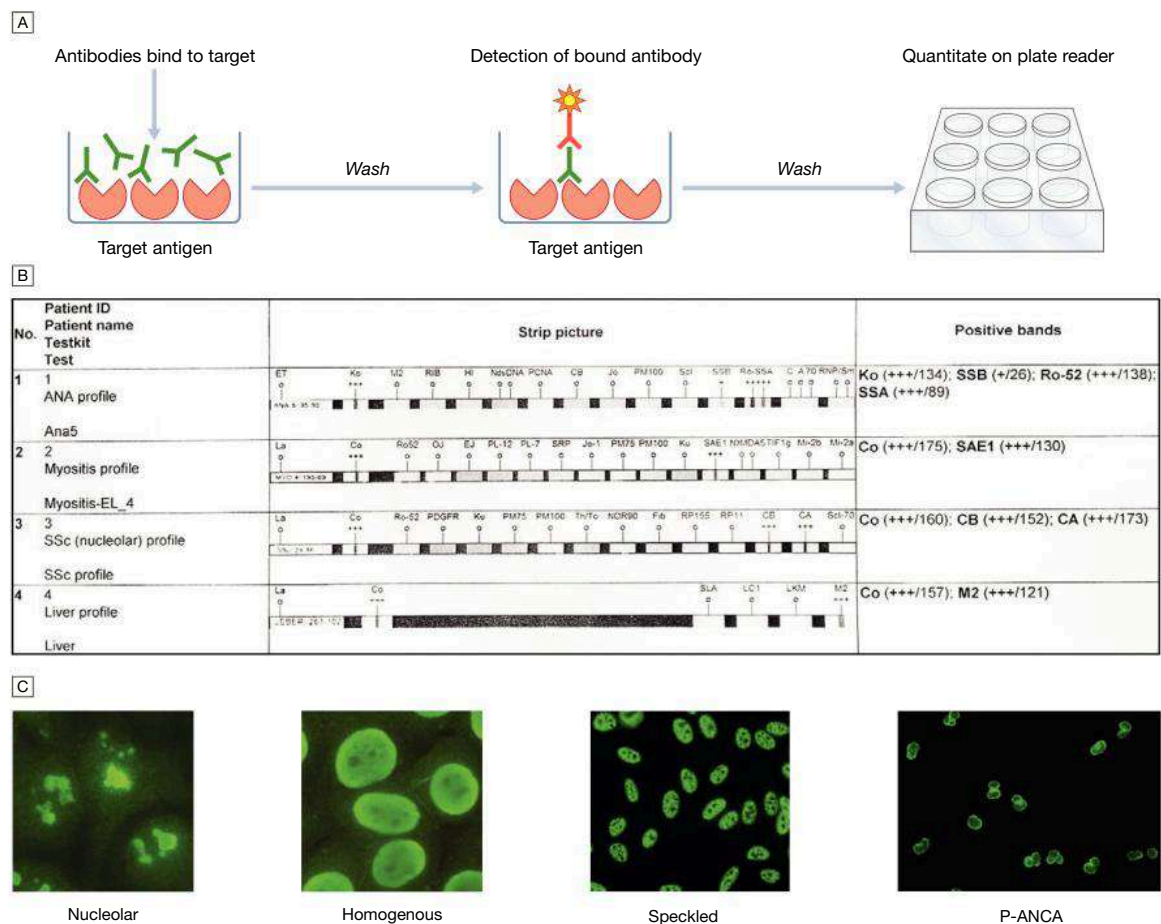

### Autoantibodies

Many autoantibodies have been identified and are used in the diagnosis and monitoring of autoimmune diseases, as discussed elsewhere in this book. Antibodies can be quantified either by titre (the maximum dilution of the serum at which the antibody can be detected) or by concentration in standardised units using an enzyme-linked immunosorbent assay (ELISA) in which the antigen is used to coat microtitre plates to which the patient's serum is added (Fig. 4.13A). Immunoblotting (Fig. 4.13B) can also be employed for autoantibody detection as well as qualitative tests in which the pattern of immunofluorescence staining is recorded

(Fig. 4.13C). Antibody testing can also be performed using Luminex technology. In this case multiple test antigens are individually bound to red and infra-red fluorescently labelled polystyrene or paramagnetic beads. Each antigen-coated bead is coated with a unique proportion of red and infrared dyes. The patient sample is incubated with these beads and if antibodies are present in the sample these will bind to the test antigens coating the beads. After washing to remove unbound antibodies, a third fluorescent dye is added and the sample is processed through a dual laser Luminex analyser, which can detect the unique spectral signatures arising from beads coated with different test antigens allowing detection of multiple antibodies present in a single patient sample.

### Complement

Measurement of complement components can be useful in the evaluation of immune complex-mediated diseases. Classical complement pathway activation leads to a decrease in circulating C4 levels and is

**Fig. 4.13 Autoantibody testing.** **A** Measurement of autoantibody levels by enzyme-linked immunosorbent assay (ELISA). The antigen of interest is used to coat microtitre plates to which patient serum is added. If autoantibodies are present, these bind to the target antigen on the microtitre plate. The amount of bound antibody is quantitated by adding a secondary antibody linked to an enzyme that converts a colourless substrate to a coloured one, which can be detected by a plate reader. **B** Detection of autoantibodies by immunoblotting. Test strips are coated with purified antigens in parallel lines. The strips are incubated with patient serum or plasma and controls. After washing to remove unbound antibody, strips are incubated with enzyme-conjugated alkaline phosphatase-labelled anti-human IgG. After washing and addition of a chromogenic substrate, an enzyme-mediated colour reaction develops. After a final wash, the strips are dried and any observed banding pattern is scanned for band intensity against an electronic template. The black bars on the strip separate the antigens being tested. Positive results are seen as vertical grey lines below the test antigen and the intensity of staining corresponds to the concentration of antibody in the patient's serum. The strength of staining is expressed both as a number and as a grade from + (weak) to +++ (strong). Note that all strips contain an internal quality control (marked as Ko or Co), to ensure the assay has worked. In the example shown, the patient sample was positive for multiple auto-antibodies in the ANA profile, the Myositis profile, the Systemic sclerosis (SSc) profile and the Liver profile. **C** Qualitative analysis of autoantibodies by patterns of indirect immunofluorescence staining. In this assay, patient serum is added to cell substrate and a secondary antibody is added with a fluorescent label to detect any bound antibody. If antibodies are present, they are detected as bright green staining using a fluorescence microscope. Different antinuclear antibody patterns may be seen in different types of connective tissue disease using a HEp2 or HEp2000 (human epithelial cell line) as substrate (see Ch. 26). Immunofluorescence can be undertaken using different substrates, according to the autoantibody under investigation. An antinucleolar ANA can be seen in systemic sclerosis, a homogenous ANA can be seen in SLE and a speckled ANA can be seen in SLE or Sjögren syndrome. In the context of small vessel vasculitis, the tissue substrate is ethanol-fixed neutrophils. Two main staining patterns of anti-neutrophil cytoplasmic antibodies (ANCA) are clinically relevant, cytoplasmic and perinuclear, seen in granulomatosis with polyangiitis and microscopic polyangiitis (see Ch. 26), the autoantibodies recognising proteinase 3 and myeloperoxidase respectively. (B and C, Nucleolar and Homogenous) Courtesy of Juliet Dunphy, Biomedical Scientist, Royal United Hospital Bath, UK; (C, Speckled and P-ANCA) Courtesy of Mr Richard Brown, Clinical Scientist in Immunology, Southwest Pathology Services, UK.

often also associated with decreased C3 levels. Serial measurement of C3 and C4 can be helpful as a surrogate measure of disease activity in conditions such as SLE.

### Cryoglobulins

Cryoglobulins are antibodies that can be directed against other immunoglobulins, which form immune complexes that precipitate in the cold. They can lead to type III hypersensitivity reactions, with typical clinical manifestations including purpuric rash, often of the lower extremities, arthralgia and peripheral neuropathy. Cryoglobulins are classified into three types, depending on the properties of the immunoglobulin involved (Box 4.16). Testing for cryoglobulins requires the transport of a serum specimen to the laboratory at 37°C. Cryoglobulins should not be confused with cold agglutinins; the latter are autoantibodies specifically directed against the I/i antigen on the surface of red cells, which can cause intravascular haemolysis in the cold (p. 958).

### Management

The management of autoimmune disease depends on the organ system involved and further details are provided elsewhere in this book. In general, treatment of autoimmune diseases involves the use of glucocorticoids and immunosuppressive agents, which are increasingly used in combination with biologic agents targeting disease-specific cytokines and their receptors. Not all conditions require immune suppression, however. For example, the management of coeliac disease involves dietary gluten withdrawal, while autoimmune hypothyroidism requires appropriate thyroxine supplementation.

## Allergy

Allergic diseases are a common and increasing cause of illness, affecting between 15% and 20% of the population at some time. They comprise a range of disorders from mild to life-threatening and affect many organs. Atopy is the tendency to produce an exaggerated IgE immune response to otherwise harmless environmental substances, while an allergic disease can be defined as the clinical manifestation of this inappropriate IgE immune response.

### Pathophysiology

The immune system does not normally respond to the many environmental substances to which it is exposed on a daily basis. In allergic individuals, however, an initial exposure to a normally harmless exogenous substance (known as an allergen) triggers the production of specific IgE antibodies by activated B cells. These bind to high-affinity IgE receptors on the surface of mast cells, a step that is not itself associated with clinical sequelae. However, re-exposure to the allergen binds to and cross-links membrane-bound IgE, which activates the mast cells, releasing a variety of vasoactive mediators (the early phase response; Fig. 4.14 and see Chapter 9). This type I hypersensitivity reaction forms the basis of an allergic reaction, which can range from sneezing and rhinorrhea to anaphylaxis (Box 4.17). In some individuals, the early phase response is followed by persistent activation of mast cells, manifest by ongoing swelling and local inflammation. This is known as the late phase reaction and is mediated by mast cell metabolites, basophils, eosinophils and macrophages. Long-standing or recurrent allergic inflammation may give rise to a chronic inflammatory response characterised by a complex infiltrate of macrophages, eosinophils and T lymphocytes, in addition to mast cells and basophils. Once this has been established, inhibition of mast cell mediators with antihistamines is clinically ineffective in isolation. Mast cell activation may also be non-specifically triggered through other signals, such as neuropeptides, anaphylotoxins and bacterial peptides.

The increasing incidence of allergic diseases is largely unexplained but one widely held theory is the 'hygiene hypothesis'. This proposes that infections in early life are critically important in maturation of the immune response and bias the immune system against the development of allergies; the high prevalence of allergic disease is the penalty for the decreased exposure to infection that has resulted from improvements in sanitation and health care. Genetic factors also contribute strongly to the development of allergic diseases. A positive family history is common in patients with allergy, and genetic association studies have identified a wide variety of predisposing variants in genes controlling innate immune responses, cytokine production, IgE levels and the ability of the epithelial barrier to protect against environmental agents. The expression of a genetic predisposition is complex; it is governed by environmental factors, such as pollutants and cigarette smoke, and the incidence of bacterial and viral infection.

i 4.16 Classification of cryoglobulins			
	Type I	Type II	Type III
<b>Immunoglobulin (Ig) isotype and specificity</b>	Isolated monoclonal IgM paraprotein with no particular specificity	Immune complexes formed by monoclonal IgM paraprotein directed towards constant region of IgG	Immune complexes formed by polyclonal IgM or IgG directed towards constant region of IgG
<b>Prevalence</b>	25%	25%	50%
<b>Disease association</b>	Lymphoproliferative disease, especially Waldenström macroglobulinaemia	Infection, particularly hepatitis C; lymphoproliferative disease	Infection, particularly hepatitis C; autoimmune disease, including rheumatoid arthritis and systemic lupus erythematosus
<b>Symptoms</b>	<i>Hyperviscosity:</i> Raynaud's phenomenon Acrocyanosis Retinal vessel occlusion Arterial and venous thrombosis	<i>Small-vessel vasculitis:</i> Purpuric rash Arthralgia Neuropathy Cutaneous ulceration, hepatosplenomegaly, glomerulonephritis, Raynaud's phenomenon	<i>Small-vessel vasculitis:</i> Purpuric rash, arthralgia Cutaneous ulceration hepatosplenomegaly, glomerulonephritis Raynaud's phenomenon
<b>Protein electrophoresis</b>	Monoclonal IgM paraprotein	Monoclonal IgM paraprotein	No monoclonal paraprotein
<b>Rheumatoid factor</b>	Negative	Strongly positive	Strongly positive
<b>Complement</b>	Usually normal	Decreased C4	Decreased C4
<b>Serum viscosity</b>	Raised	Normal	Normal

**Fig. 4.14 Type I (immediate) hypersensitivity response.** **A** After an encounter with allergen, B cells produce immunoglobulin E (IgE) antibody against the allergen. **B** Specific IgE antibodies bind to circulating mast cells via high-affinity IgE cell surface receptors. **C** On re-encounter with allergen, the allergen binds to the IgE antibody-coated mast cells. This cross-linking of the IgE triggers mast cell activation with release of vasoactive mediators.

#### 4.17 Clinical manifestations of allergy

##### Dermatological

- Urticaria
- Atopic eczema if chronic
- Allergic contact eczema
- Angioedema

##### Respiratory

- Asthma
- Atopic rhinitis

##### Ophthalmological

- Allergic conjunctivitis

##### Gastrointestinal

- Food allergy

##### Other

- Anaphylaxis
- Drug allergy
- Allergy to insect venom

### Clinical features

Common presentations of allergic disease are shown in [Box 4.17](#). Those that affect the respiratory system and skin are discussed in more detail in [Chapters 17 and 27](#), respectively. Here we focus on general principles of the approach to the allergic patient and some specific allergies. The management of acute anaphylaxis is discussed in [Chapter 9](#).

#### Insect venom allergy

Local non-IgE-mediated reactions to insect stings are common and may cause extensive swelling around the site lasting up to 7 days. These usually do not require specific treatment. Toxic reactions to venom after multiple (50–100) simultaneous stings may mimic anaphylaxis. In addition, exposure to large amounts of insect venom frequently stimulates the production of IgE antibodies, and thus may be followed by allergic reactions to single stings. Allergic IgE-mediated reactions vary from mild to life-threatening. Antigen-specific immunotherapy (desensitisation; see below) with bee or wasp venom can reduce the incidence of recurrent anaphylaxis from 50% to 60% to approximately 10%, but requires 3–5 years of treatment or more.

#### Peanut allergy

Peanut allergy is the most common food-related allergy. More than 50% of patients present before the age of 3 years and some individuals react to their first known exposure to peanuts, thought to result from sensitisation to arachis oil in topical creams. Peanuts are ubiquitous in the Western diet, and every year up to 25% of peanut-allergic individuals experience a reaction as a result of inadvertent exposure.

#### Birch oral allergy syndrome

This syndrome is characterised by the combination of birch pollen hay fever and local oral symptoms, including itch and angioedema, after contact with certain raw fruits, raw vegetables and nuts. Cooked fruits and vegetables are tolerated without difficulty. It is due to shared or cross-reactive allergens that are destroyed by cooking or digestion, and can be confirmed by skin-prick testing using fresh fruit. Severe allergic reactions are unusual.

#### Diagnosis

When assessing a patient with a complaint of allergy, it is important to identify what the patient means by the term, as up to 20% of the UK population describe themselves as having a food allergy; in fact, less than 1% have true allergy, as defined by an IgE-mediated hypersensitivity reaction confirmed on double-blind challenge. The nature of the symptoms should be established and specific triggers identified, along with the predictability of a reaction, and the time lag between exposure to a potential allergen and onset of symptoms. An allergic reaction usually occurs within minutes of exposure and provokes predictable, reproducible symptoms such as angioedema, urticaria and wheezing. Specific enquiry should be made about other allergic symptoms, past and present, and about a family history of allergic disease. Potential allergens in the home and workplace should be identified. A detailed drug history should always be taken, including details of adherence to medication, possible adverse effects and the use of over-the-counter or complementary therapies.

#### Investigations

##### Skin-prick tests

Skin-prick testing is a key investigation in the assessment of patients suspected of having allergy. A droplet of diluted standardised allergen is placed on the forearm and the skin is superficially punctured through the droplet with a sterile lancet. Positive and negative control material must be included in the assessment. After 15 minutes, a positive response is indicated by a local weal and flare response 2 mm or more larger than the negative control. A major advantage of skin-prick testing is that the patient can clearly see the results, which may be useful in gaining adherence to avoidance measures. Disadvantages include the remote risk of a severe allergic reaction, so resuscitation facilities should be available. Results are unreliable in patients with extensive skin disease. Antihistamines inhibit the magnitude of the response and should be discontinued for at least 3 days before testing; low-dose glucocorticoids do not influence test results. A number of other prescribed medicines can also lead to false-negative results, including amitriptyline and risperidone.

### Specific IgE tests

An alternative to skin-prick testing is the quantitation of IgE directed against the suspected allergen. The sensitivity and specificity of specific IgE tests (previously known as radioallergen sorbent tests, RAST) are lower than those of skin-prick tests. However, IgE tests may be very useful if skin testing is inappropriate, such as in patients taking antihistamines or those with severe skin disease or dermatographism. They can also be used to test for cross-reactivity – for example, with multiple insect venoms, where component-resolved diagnostics, using recombinant allergens, is now increasingly used rather than crude allergen extract. Component resolved diagnostics (CRD) is a more recent development in allergic investigation. CRD uses purified native or recombinant allergens to detect specific IgE directed against individual allergenic molecules. CRD can discriminate genuine sensitisation from sensitisation due to cross reactivity and in some cases can be used in risk stratification. For example, in patients with hazelnut allergy, the clinical features can be mild and most consistent with the oral allergy syndrome rather than primary nut allergy, in which case CRD may confirm specific IgE to Cor a1, a birch pollen homologue, hence the association with the oral allergy syndrome, whereas patients with primary hazelnut allergy positive for Cor a9 or Cor a14 tend to have more severe allergy. Severity of reaction in peanut allergy can also be associated with specific Ara h allergens, which are present in peanuts. Such risk stratification can impact on patient management, for example, identifying patients who may require an adrenaline auto-injector.

### Supervised exposure to allergen

Tests involving supervised exposure to an allergen (allergen challenge) are usually performed in specialist centres on carefully selected patients, and include bronchial provocation testing, nasal challenge, and food or drug challenge. These may be particularly useful in the investigation of occupational asthma or food allergy. Patients can be considered for challenge testing when skin tests and/or IgE tests are negative, as they can be helpful in ruling out allergic disease.

### Mast cell tryptase

Measurement of serum mast cell tryptase is extremely useful in investigating a possible anaphylactic event. Ideally, measurements should be made at the time of the reaction following appropriate resuscitation, and 3 hours and 24 hours later. The basis of the test is the fact that circulating levels of mast cell degranulation products rise dramatically to peak 1–2 hours after a systemic allergic reaction. Tryptase is the most stable of these and is easily measured in serum.

### Serum total IgE

Serum total IgE measurements are not routinely indicated in the investigation of allergic disease, other than to aid in the interpretation of specific IgE results, as false-positive specific IgEs are common in patients with atopy, who often have a high total IgE level. Although atopy is the most common cause of an elevated total IgE in developed countries, there are many other causes, including parasitic and helminth infections, lymphoma, drug reactions and eosinophilic granulomatosis with polyangiitis (previously known as Churg–Strauss vasculitis). Normal total IgE levels do not exclude allergic disease.

### Eosinophilia

Peripheral blood eosinophilia is common in atopic individuals but lacks specificity. Eosinophilia of more than 20% or an absolute eosinophil count over  $1.5 \times 10^9/L$  should initiate a search for a non-atopic cause, such as eosinophilic granulomatosis with polyangiitis or parasitic infection.

### Management

Several approaches can be deployed in the management of allergic individuals, as discussed below.

### Avoidance of the allergen

This is indicated in all cases and should be rigorously attempted, with the advice of specialist dietitians and occupational physicians as necessary.

### Antihistamines

Antihistamines are useful in the management of allergy as they inhibit the effects of histamine on tissue  $H_1$  receptors. Long-acting, non-sedating preparations are particularly useful for prophylaxis.

### Glucocorticoids

These are highly effective in allergic disease, and if used topically, adverse effects can be minimised.

### Sodium cromoglicate

Sodium cromoglicate stabilises the mast cell membrane, inhibiting release of vasoactive mediators. It is effective as a prophylactic agent in asthma and allergic rhinitis but has no role in management of acute attacks. It is poorly absorbed and therefore generally ineffective in the management of food allergies.

### Antigen-specific immunotherapy

This involves the sequential administration of increasing doses of allergen extract over a prolonged period of time. The mechanism of action is not fully understood but it is highly effective in the prevention of insect venom anaphylaxis and of allergic rhinitis secondary to grass pollen allergy. The traditional route of administration is by subcutaneous injection, which carries a risk of anaphylaxis and should be performed only in specialised centres. Sublingual immunotherapy is also increasingly used. Clinical studies to date do not support the use of allergen immunotherapy for food hypersensitivity, although this is an area of active investigation.

### Omalizumab

Omalizumab is a monoclonal antibody directed against IgE; it inhibits the binding of IgE to mast cells and basophils. It is licensed for treatment of refractory chronic spontaneous urticaria and also for severe persistent allergic asthma that has failed to respond to standard therapy. The dose and frequency are determined by baseline IgE (measured before the start of treatment) and body weight. It is under investigation for allergic rhinitis but not yet approved for this indication.

### Adrenaline (epinephrine)

Adrenaline given by injection in the form of a pre-loaded self-injectable device can be life-saving in the acute management of anaphylaxis (see [Ch. 9](#)).

## Angioedema

Angioedema is an episodic, localised, non-pitting swelling of submucous or subcutaneous tissues.

### Pathophysiology

The causes of angioedema are summarised in [Box 4.18](#). It may be a manifestation of allergy or non-allergic degranulation of mast cells in response to drugs and toxins. In these conditions the main cause is mast cell degranulation with release of histamine and other vasoactive mediators. In hereditary angioedema, the cause is C1 inhibitor deficiency, which leads to increased local release of bradykinin. Angiotensin-converting enzyme (ACE) inhibitor-induced angioedema also occurs as the result of increased bradykinin levels due to inhibition of its breakdown.

### Clinical features

Angioedema is characterised by soft-tissue swelling that most frequently affects the face ([Fig. 4.15](#)) but can also affect the extremities and genitalia. Involvement of the larynx or tongue may cause life-threatening respiratory tract obstruction, and oedema of the intestinal mucosa may cause abdominal pain and distension.

### Investigations

Differentiating the mechanism of angioedema is important in determining the most appropriate treatment. A clinical history of allergy or drug

## i

## 4.18 Types of angioedema

	Allergic reaction to specific trigger	Idiopathic angioedema	Hereditary angioedema	ACE-inhibitor associated angioedema
<b>Pathogenesis</b>	IgE-mediated degradation of mast cells	Non-IgE-mediated degranulation of mast cells	C1 inhibitor deficiency, with resulting increased local bradykinin concentration	Inhibition of breakdown of bradykinin
<b>Key mediator</b>	Histamine	Histamine	Bradykinin	Bradykinin
<b>Prevalence</b>	Common	Common	Rare autosomal dominant disorder	0.1%–0.2% of patients treated with ACE inhibitors
<b>Clinical features</b>	Usually associated with urticaria History of other allergies common Follows exposure to specific allergen, in food, animal dander or insect venom	Usually associated with urticaria May be triggered by physical stimuli such as heat, pressure or exercise Dermatographism common Occasionally associated with underlying infection or thyroid disease	Not associated with urticaria or other features of allergy Does not cause anaphylaxis May cause life-threatening respiratory tract obstruction Can cause severe abdominal pain	Not associated with urticaria Does not cause anaphylaxis Usually affects the head and neck, and may cause life-threatening respiratory tract obstruction Can occur years after the start of treatment
<b>Investigations</b>	Specific IgE tests or skin-prick tests	Specific IgE tests and skin-prick tests often negative Hypothyroidism should be excluded	Complement C4 (invariably low in acute attacks) C1 inhibitor levels	No specific investigations
<b>Treatment</b>	Allergen avoidance Antihistamines	Antihistamines are mainstay of treatment and prophylaxis	Unresponsive to antihistamines Anabolic steroids C1 inhibitor concentrate or icatibant for acute attacks	ACE inhibitor should be discontinued ARBs should be avoided if possible unless there is a strong indication
<b>Associated drug reactions</b>	Specific drug allergies	NSAIDs Opioids, radiocontrast media		ACE inhibitors, ARBs

(ACE = angiotensin-converting enzyme; ARBs = angiotensin II receptor blockers; IgE = immunoglobulin E; NSAIDs = non-steroidal anti-inflammatory drugs)

exposure can give clues to the underlying diagnosis. If no obvious trigger can be identified, measurement of complement C4 is useful in differentiating hereditary and acquired angioedema from other causes. If C4 levels are low, further investigations should be initiated to look for evidence of C1 inhibitor deficiency.

### Management

Management depends on the underlying cause. Angioedema associated with allergen exposure generally responds to antihistamines and glucocorticoids. Following acute management of angioedema secondary to drug therapy, drug withdrawal should prevent further attacks, although ACE inhibitor-induced angioedema can continue for a limited period post drug withdrawal. Management of angioedema associated with C1 inhibitor deficiency is discussed below.

### Hereditary angioedema

Hereditary angioedema (HAE), also known as inherited C1 inhibitor deficiency, is an autosomal dominant disorder caused by decreased production or activity of C1 inhibitor protein. This complement regulatory protein inhibits spontaneous activation of the classical complement pathway (see Fig. 4.4). It also acts as an inhibitor of the kinin cascade, activation of which increases local bradykinin levels, giving rise to local pain and swelling.

#### Clinical features

The angioedema in HAE may be spontaneous or triggered by local trauma or infection. Multiple parts of the body may be involved, especially the face, extremities, upper airway and gastrointestinal tract. Oedema of the intestinal wall causes severe abdominal pain and many patients with undiagnosed HAE undergo exploratory laparotomy. The most important complication is laryngeal obstruction, often associated with minor dental procedures, which can be fatal. Episodes of angioedema are self-limiting

**Fig. 4.15 Angioedema.** This young man has hereditary angioedema. **A** Normal appearance. **B** During an acute attack. From Helbert M. *Flesh and bones of immunology*. Edinburgh: Churchill Livingstone, Elsevier Ltd; 2006.

and usually resolve within 48 hours. Patients with HAE generally present in adolescence but may go undiagnosed for many years. A family history can be identified in 80% of cases. HAE is not associated with allergic diseases and is specifically not associated with urticaria.

#### Investigations

Acute episodes are accompanied by low C4 levels; a low C4 during an episode of angioedema should therefore trigger further investigation. The diagnosis can be confirmed by measurement of C1 inhibitor levels and function.

#### Management

Severe acute attacks should be treated with plasma-derived or recombinant C1 inhibitor or the bradykinin receptor antagonist icatibant. Anabolic

steroids, such as danazol, can be used to prevent attacks and act by increasing endogenous production of complement proteins, but is limited by treatment toxicity. Tranexamic acid can be helpful as prophylaxis in some patients. C1 inhibitor concentrate can also be used as prophylaxis, for example for surgical or dental intervention. Patients can be taught to self-administer therapy and should be advised to carry a MedicAlert or similar. More recently, a humanised monoclonal antibody which inhibits plasma kallikrein activity, limiting the production of bradykinin, has been developed for the prevention of recurrent attacks in patients with C1 inhibitor deficiency. This is not licensed for acute attacks.

### Acquired C1 inhibitor deficiency

This rare disorder is clinically indistinguishable from HAE but presents in late adulthood. It is associated with autoimmune and lymphoproliferative diseases. Most cases are due to the development of autoantibodies to C1 inhibitor, but the condition can also be caused by autoantibodies that activate C1. Treatment of the underlying disorder may induce remission of angioedema. As with HAE, a low C4 is seen during acute episodes.

## Pregnancy and the immune system

Major adaptations occur in the immune system during pregnancy so that the mother does not mount an immune response to the developing fetus. These adaptations can influence the risk and severity of certain infectious diseases such as varicella pneumonia (see p. 1271) as well as the activity of some autoimmune diseases. Some considerations for

### 4.19 Immunological diseases in pregnancy

#### Allergic disease

- **Maternal dietary restrictions during pregnancy or lactation:** current evidence does not support these for prevention of allergic disease.
- **Breastfeeding for at least 4 months:** prevents or delays the occurrence of atopic dermatitis, cow's milk allergy and wheezing in early childhood, as compared with feeding formula milk containing intact cow's milk protein.

#### Autoimmune disease

- **Suppressed T-cell-mediated immune responses in pregnancy:** may suddenly reactivate post-partum. Some autoimmune diseases may improve during pregnancy but flare immediately after delivery. Systemic lupus erythematosus (SLE) is an exception, however, as it is prone to exacerbation in pregnancy or the puerperium.
- **Passive transfer of maternal antibodies:** can mediate autoimmune disease in the fetus and newborn, including SLE, Graves' disease and myasthenia gravis.
- **Antiphospholipid syndrome** (p. 987): an important cause of fetal loss, intrauterine growth restriction and pre-eclampsia.
- **HIV in pregnancy:** see p. 367.

the development and management of immunological diseases during pregnancy and breastfeeding are summarised in [Box 4.19](#).

## Transplantation and graft rejection

Transplantation provides the opportunity for definitive treatment of end-stage organ disease. The major complications are graft rejection, drug toxicity and infection consequent to immunosuppression. Transplant survival continues to improve, as a result of the introduction of less toxic immunosuppressive agents and increased understanding of the processes of transplant rejection. Stem cell transplantation and its complications are discussed in more detail in [Chapter 25](#).

### Transplant rejection

Solid organ transplantation inevitably stimulates an aggressive immune response by the recipient, unless the transplant is between monozygotic twins. The type and severity of the rejection response is determined by the genetic disparity between the donor and recipient, the immune status of the host and the nature of the tissue transplanted ([Box 4.20](#)). The most important genetic determinant is the difference between donor and recipient HLA proteins. The extensive polymorphism of these proteins means that donor HLA antigens are almost invariably recognised as foreign by the recipient immune system, unless an active attempt has been made to minimise incompatibility.

- **Hyperacute rejection** results in rapid and irreversible destruction of the graft (see [Box 4.20](#)). It is mediated by pre-existing recipient antibodies against donor HLA antigens, which arise as a result of previous exposure through transplantation, blood transfusion or pregnancy. It is very rarely seen in clinical practice, as the use of screening for anti-HLA antibodies and pre-transplant cross-matching ensures the prior identification of such recipient–donor incompatibility.
- **Acute cellular rejection** is the most common form of graft rejection. It is mediated by activated T lymphocytes and results in deterioration in graft function. If allowed to progress, it may cause fever, pain and tenderness over the graft. It is usually amenable to increased immunosuppressive therapy.
- **Acute vascular rejection** is mediated by antibody formed de novo after transplantation. It is more curtailed than the hyperacute response because of the use of intercurrent immunosuppression but it is also associated with reduced graft survival. Aggressive immunosuppressive therapy is indicated and physical removal of antibody through plasmapheresis may be indicated in severe causes. Not all post-transplant anti-donor antibodies cause graft damage; their consequences are determined by specificity and ability to trigger other immune components, such as the complement cascade.

### 4.20 Classification of transplant rejection

Type	Time	Pathological findings	Mechanism	Treatment
Hyperacute rejection	Minutes to hours	Thrombosis, necrosis	Pre-formed antibody to donor antigens results in complement activation (type II hypersensitivity)	None – irreversible graft loss
Acute cellular rejection	5–30 days	Cellular infiltration	CD4 <sup>+</sup> and CD8 <sup>+</sup> T cells (type IV hypersensitivity)	Increase immunosuppression
Acute vascular rejection	5–30 days	Vasculitis	Antibody and complement activation	Increase immunosuppression
Chronic allograft failure	> 30 days	Fibrosis, scarring	Immune and non-immune mechanisms	Minimise drug toxicity, control hypertension and hyperlipidaemia

**i** 4.21 Immunosuppressive drugs used in transplantation

Drug	Mechanism of action	Major adverse effects
<b>Anti-proliferative agents</b> Azathioprine, mycophenolate mofetil	Inhibit lymphocyte proliferation by blocking DNA synthesis May be directly cytotoxic at high doses	Increased susceptibility to infection Leucopenia Hepatotoxicity
<b>Calcineurin inhibitors</b> Ciclosporin, tacrolimus	Inhibit T-cell signalling; prevent lymphocyte activation; block cytokine transcription	Increased susceptibility to infection Hypertension Nephrotoxicity Diabetogenic (especially tacrolimus) Gingival hypertrophy, hirsutism (ciclosporin)
<b>Glucocorticoids</b>	Decrease phagocytosis and release of proteolytic enzymes; decrease lymphocyte activation and proliferation; decrease cytokine production; decrease antibody production	Increased susceptibility to infection Multiple other complications
<b>Anti-thymocyte globulin (ATG)</b>	Antibodies to cell surface proteins deplete or block T cells	Profound non-specific immunosuppression Increased susceptibility to infection
<b>Basiliximab</b>	Monoclonal antibody directed against CD25 (IL-2R $\alpha$ chain), expressed on activated T cells	Increased susceptibility to infection Gastrointestinal side-effects
<b>Belatacept</b>	Selectively inhibits T-cell activation through blockade of CD80/CD86	Increased susceptibility to infection and malignancy Gastrointestinal side-effects Hypertension Anaemia/leucopenia

- *Chronic allograft failure*, also known as chronic rejection, is a major cause of graft loss. It is associated with proliferation of transplant vascular smooth muscle, interstitial fibrosis and scarring. The pathogenesis is poorly understood but contributing factors include immunological damage caused by subacute rejection, hypertension, hyperlipidaemia and chronic drug toxicity.

**Investigations**

**Pre-transplantation testing**

HLA typing determines an individual's HLA polymorphisms and facilitates donor–recipient matching. Potential transplant recipients are also screened for the presence of anti-HLA antibodies. The recipient is excluded from receiving a transplant that carries these alleles.

Donor–recipient cross-matching is a functional assay that directly tests whether serum from a recipient (which potentially contains anti-donor antibodies) is able to bind and/or kill donor lymphocytes. It is specific to a prospective donor–recipient pair and is done immediately prior to transplantation. A positive cross-match is a contraindication to transplantation because of the risk of hyperacute rejection.

**Post-transplant biopsy: C4d staining**

C4d is a fragment of the complement protein C4 (see Fig. 4.4). Deposition of C4d in graft capillaries indicates local activation of the

classical complement pathway and provides evidence of antibody-mediated damage. This is useful in the early diagnosis of vascular rejection.

**Complications of transplant immunosuppression**

Transplant recipients require indefinite treatment with immunosuppressive agents. In general, two or more immunosuppressive drugs are used in synergistic combination in order to minimise adverse effects (Box 4.21). The major complications of long-term immunosuppression are infection and malignancy. The risk of some opportunistic infections may be minimised through the use of prophylactic medication, such as ganciclovir for cytomegalovirus prophylaxis and trimethoprim–sulfamethoxazole for *Pneumocystis* prophylaxis. Immunisation with killed vaccines is appropriate, although the immune response may be curtailed. Live vaccines should not be given.

The increased risk of malignancy arises because T-cell suppression results in failure to control viral infections associated with malignant transformation. Virus-associated tumours include lymphoma (associated with Epstein–Barr virus), Kaposi's sarcoma (associated with human herpesvirus 8) and skin tumours (associated with human papillomavirus). Immunosuppression is also linked with a small increase in the incidence of common cancers not associated with viral infection (such as lung, breast and colon cancer), reflecting the importance of T cells in anti-cancer surveillance.

**Organ donation**

The major problem in transplantation is the shortage of organ donors. Cadaveric organ donors are usually previously healthy individuals who experience brainstem death, frequently as a result of road traffic accidents or cerebrovascular events. Even if organs were obtained from all potential cadaveric donors, though, their numbers would be insufficient to meet current demands. An alternative is the use of living donors. Altruistic living donation, usually from close relatives, is widely used in renal transplantation. Living organ donation is inevitably associated with some risk to the donor and it is highly regulated to ensure appropriate appreciation of the risks involved. Because of concerns about coercion and exploitation, non-altruistic organ donation (the sale of organs) is illegal in most countries.

**Tumour immunology**

Surveillance by the immune system is critically important in monitoring and removing damaged and mutated cells as they arise. The ability of the immune system to kill cancer cells effectively is influenced by tumour immunogenicity and specificity. Many cancer antigens are poorly expressed and specific antigens can mutate, either spontaneously or in response to treatment, which can result in evasion of immune responses. In addition, the inhibitory pathways that are used to maintain self-tolerance and limit collateral tissue damage during antimicrobial immune responses can be co-opted by cancerous cells to evade immune destruction. Recognition and understanding of these immune checkpoint pathways has led to the development of a number of new treatments for cancers that are otherwise refractory to treatment. Immune checkpoint blockade enhances anti-tumour immunity by blocking down-regulators of immune activation. Immune checkpoint inhibitors targeting CTLA-4, PD1 and PD-L1, such as ipilimumab, nivolumab, and pembrolizumab, have shown benefit in a number of tumour types, including melanoma, non-small cell lung cancer, urothelial cancers, colorectal malignancy and classic Hodgkin's lymphoma. These agents can, however, have serious inflammatory side effects, with immune-related adverse events most commonly involving the skin, liver, endocrine and gastrointestinal tracts, which may be treatment limiting. The effects of the different agents vary, with lung and thyroid involvement being more common with anti-PD1 therapy, colitis and hypophysitis being more common with anti-CTLA-4 therapy, with

anti-CTLA-4 therapy-related events often being more severe. However, patients who have had a favourable response to immune checkpoint blockade but discontinue as a result of immune-related adverse events may maintain their anti-tumour response. Glucocorticoids are considered first line therapy for these side effects, with additional immune suppression if required. The development of autoimmunity reflects the importance of these pathways in the control of self-tolerance.

Another recent advance is CAR-T cell therapy, in which genetically engineered, chimaeric antigen receptor T cells are specifically developed for an individual patient, with effective reprogramming of the patient's immune cells, which are then used to target their cancer. This has been applied to certain otherwise treatment-refractory haematological malignancies (Ch. 25). Not only is it a very expensive treatment, but cytokine storm and subsequent antibody deficiency are predictable side effects of the CAR T-cell therapies directed at B-cell antigens, requiring management in their own right.

## Further information

### Websites

[allergy.org.au](http://allergy.org.au) An Australasian site providing information on allergy, asthma and immune diseases.

[allergyuk.org](http://allergyuk.org) UK site for patients and health-care professionals.

[anaphylaxis.org.uk](http://anaphylaxis.org.uk) Provides information and support for patients with severe allergies.

[info4pi.org](http://info4pi.org) A US site managed by the non-profit Jeffrey Modell Foundation, which provides extensive information about primary immune deficiencies.

## Multiple Choice Questions

4.1. In the investigation of allergy, which of the following statements are correct?

- A. Mast cell tryptase is labile in serum and therefore not a useful biomarker of mast cell activation
- B. Measurement of total IgE is not useful
- C. Component resolved diagnostics can have predictive value in some food allergies
- D. Skin testing is not affected by antihistamine medication
- E. Some antidepressant medications can lead to false-negative skin test results

Answer: C and E.

Mast cell tryptase is stable in serum, making it a particularly convenient biomarker of mast cell activation. A total IgE can be helpful in atopic patients as a high total level can be associated with false-positive specific IgEs. Component resolved diagnostics uses purified native or recombinant allergens to detect specific IgE directed against individual allergenic molecules. CRD can discriminate genuine sensitisation from sensitisation due to cross reactivity and in some cases can be used in risk stratification, having predictive value, such as in peanut and some nut allergy. A number of medications, including certain antidepressant classes, can have antihistamine properties and thereby interfere with skin testing. Patients should be advised to discontinue interacting medications in advance of testing.

4.2. Which of the following are required for naïve T-cell activation?

- A. Antigen processing by antigen-presenting cells
- B. Antigenic peptide presentation by pattern recognition receptors
- C. HLA class 1 for CD4 T cells
- D. Co-stimulatory molecules
- E. Intracellular T-cell signalling

Answer: A, D and E.

Unlike B cells, which recognise native antigen, T cells require antigen processing through professional antigen-presenting cells, with presentation of antigenic peptide by self-HLA molecules expressed at the APC surface. The Ag-HLA complex then interacts with the T-cell receptor. Pattern recognition receptors are expressed by phagocytic cells and recognise pathogen-associated molecular patterns on invading micro-organisms. They do not present antigen to T cells. CD4 T cells recognise antigenic peptide presented by HLA class II molecules; CD8 T cells recognise antigenic peptide presented by HLA class I molecules. A second signal, known as co-stimulation, is required for naïve T-cell activation. Downstream intracellular T cells signalling then drives T-cell proliferation.

4.3. Which of the following statements are correct regarding T-cell populations?

- A. CD4 T cells kill virally infected cells through production of pore-forming molecules such as perforin and release of enzymes triggering apoptosis of the target cell
- B. CD8 T cells are important in defence against viral infection
- C. Th1 (T-helper) cells typically produce IL-2, IFN  $\gamma$  and TNF- $\alpha$
- D. T regs are regulatory CD4 T cells that promote activation of other cells and augment autoimmune disease
- E. Th-17 cells are pro-inflammatory cells that produce IL-17 and have a key role in defence against extracellular bacteria and fungi

Answer: B, C and E.

CD8 T cells, not CD4 T cells, kill infected cells directly through the production of pore-forming molecules such as perforin and release of enzymes triggering apoptosis of the target cell. CD8 T cells are particularly important in defence against viral infection. Th1 (T-helper) cells typically produce IL-2, IFN- $\gamma$  and TNF- $\alpha$ , and support the development of delayed-type hypersensitivity responses. T-regulatory cells (T regs) are a subset of specialised CD4+ lymphocytes important in actively suppressing activation of other cells and preventing autoimmune disease. They produce cytokines such as TGF-beta and IL-10. Th17 cells are pro-inflammatory cells defined by their production of IL-17. They have a key role in defence against extracellular bacteria and fungi. They also have a role in the development of autoimmune disease.

4.4. In tumour immunology, which of the following statements are correct?

- A. NK cells have an important role in immune surveillance
- B. Tumour cells reliably express HLA molecules to allow immune recognition by T cells
- C. Immune checkpoint blockade includes anti-CTLA and anti-PD1 pathways
- D. Autoimmune disease is a recognised complication of immune checkpoint blockade in tumour therapy
- E. Tumour progression occurs rapidly if immune checkpoint blockade is withdrawn

Answer: A, C and D.

NK cells have an important role in tumour surveillance especially as tumour cells lose their HLA expression, thereby allowing NK cell activation. Loss of HLA expression is one of the mechanisms by which tumours can evade T-cell immunity. Immune checkpoint blockade includes antibodies directed at the normally downregulatory pathways, thereby allowing immune cells to be active against the tumour. Some patients maintain the anti-tumour effect of immune checkpoint blockade despite treatment withdrawal in the event of drug toxicity.

4.5. In the context of organ transplantation, which of the following statements are correct?

- A. The major complications are graft rejection, drug toxicity and infection
- B. HLA incompatibility does not have a bearing on transplant outcome
- C. Acute cellular rejection is predominantly mediated by activated B cells
- D. Post-transplantation, failure to control viral infections associated with malignant transformation leads to an increased risk of malignancy
- E. Co-stimulatory blockade has no role in post-transplant immune suppression

Answer: A and D.

The major complications of transplantation are graft rejection, drug toxicity and infection consequent to immunosuppression. Solid organ transplantation stimulates an aggressive immune response by the recipient, unless the transplant is between monozygotic twins. The most important genetic determinant is the difference between donor and recipient HLA proteins. The polymorphism of these proteins means that donor HLA antigens are almost invariably recognised as foreign by the recipient immune system, unless an active attempt has been made to minimise incompatibility. Acute cellular rejection is mediated by activated T lymphocytes and results in deterioration in graft function. The risk of

post-transplant malignancy arises because T-cell suppression results in failure to control viral infections associated with malignant transformation, e.g. lymphoma associated with Epstein–Barr virus, Kaposi's sarcoma associated with human herpesvirus 8 and skin tumours associated

with human papillomavirus. Co-stimulatory blockade, using the CTLA-4 fusion protein belatacept, with high affinity for CD80/86 on T cells, selectively inhibits T-cell activation and has a role in post-transplant immune suppression.

The UK Faculty of Public Health defines public health as ‘The science and art of promoting and protecting health and well-being, preventing ill-health and prolonging life through the organised efforts of society’. This recognises that there is a collective responsibility for the health of the population which requires partnerships between government, health services and other partners to promote and protect health and prevent disease. Population health has been defined as ‘the health outcomes of a group of individuals, including the distribution of such outcomes within the group’. Medical doctors can play a role in all these efforts to improve health both as part of their clinical work but also through supporting broader actions to improve public health.

## Global burden of disease and underlying risk factors

The Global Burden of Disease (GBD) exercise was initiated by the World Bank in 1992, with first estimates appearing in the World Development Report in 1993. Regular updated estimates have been published since that time together with projections of future disease burden. The aim of the exercise was to produce reliable and internally consistent estimates of disease burden for all diseases and injuries and to assess their physiological, behavioural and social risk factors so that this information could be made available to health workers, researchers and policy-makers.

The GBD exercise adopted the metric ‘disability life year’ or DALY to describe population health. This combines information about premature mortality in a population (measured as Years of Life Lost from an ‘expected’ life expectancy) and years of life lived with disability (Years of Life lived with Disability (YLD), which is weighted by a severity factor). The International Classification of Disease (ICD) rules, which assign one cause to each death, are followed. All estimates are presented by age and sex groups and by regions of the world. Many countries now also report their own national burden of disease data.

### Life expectancy

Global life expectancy at birth increased from 61.7 years in 1980 to 73.0 years in 2017, an increase of about 0.3 years per calendar year. This change is due to a substantial fall in child mortality (mainly due to common infections) partly offset by rises in mortality from adult conditions such as diabetes and chronic kidney disease. Some areas have not shown these increases in life expectancy in men, often due to war and interpersonal violence.

### Global causes of death and disability

Box 5.1 shows a ranked list of the major causes of global deaths in 2019. Communicable, maternal, neonatal and nutritional causes accounted for about one-quarter of deaths worldwide – down from about one-third in 1990. In contrast, deaths from non-communicable diseases are increasing in importance and now account for about two-thirds of all deaths globally, including about 18.5 million from cardiovascular disease (ischaemic heart disease and stroke), 10 million from cancer and about 4 million from chronic respiratory diseases. The age standardised death rates for most diseases globally are falling. However, despite this, the numbers of deaths from many diseases are rising due to global population growth and the change in age structure of the population to older ages and this is placing an increasing burden on health systems. For a few conditions (e.g. HIV/AIDS, diabetes mellitus and chronic kidney disease) age-standardised death rates continue to rise. Within this overall pattern, significant regional variations exist – for example, communicable, maternal, neonatal and nutritional causes still account for about two-thirds of premature mortality in sub-Saharan Africa.

GBD also provides estimates of disability from disease (Box 5.2). This has raised awareness of the importance of conditions like depression and other common mental health conditions, low back and neck pain

(CKD = chronic kidney disease)  
From GBD 2019. <https://vizhub.healthdata.org/gbd-compare/>.

and other musculo-skeletal conditions, and asthma, which account for a relatively large disease burden but relatively few deaths. This in turn has resulted in greater health policy priority given to these conditions. Since the policy focus in national health systems is increasingly on keeping people healthy rather than only on reducing premature deaths it is important to have measures of these health outcomes.

It is important to recognise that although these estimates represent the best overall picture of burden of disease globally, they are based on limited and imperfect data. Nevertheless, the quality of data underlying the estimates and the modelling processes are improving steadily over time and provide an increasingly robust basis for evidence-based health planning and priority setting.

### Risk factors underlying disease

Box 5.3 shows a ranked list of the main risk factors underlying GBD in 2019 and how this ranking has changed over the past 29 years. A number of key insights have been identified in this, the most recent, GBD exercise:

- Socio-demographic development has been progressing steadily since 1990 but it has increased faster in countries with the highest socio-demographic development index and thus gaps have been widening.

5.3 Global risk factors – top 10 ranked causes 2019 [rank in 1990]	
1.	High blood pressure [7]
2.	Smoking/second hand smoke exposure [5]
3.	High fasting blood glucose [11]
4.	Low birth weight [2]
5.	High BMI [16]
6.	Short gestation [3]
7.	Ambient particulate matter pollution [13]
8.	High LDL cholesterol [14]
9.	Alcohol use [15]
10.	Household air pollution [4]

\*Risk factors ranked by % of burden of disease they cause.  
(BMI = body mass index; LDL = low density lipoprotein)  
From *GBD 2019 Diseases and Injuries Collaborators. Global burden of 369 diseases and injuries in 204 countries and territories, 1990–2019: a systematic analysis for the Global Burden of Disease Study 2019. Lancet 2020; 396:1204–1222.*

- Health systems need to transform to be better able to respond to the changing pattern of NCDs and disabilities.
- The Millennium Development Goal (MDG) programme from 2000 to 2015 has led to faster progress in reducing deaths from maternal, child and neonatal conditions/TB/HIV/malaria but this level of attention now needs to be directed at NCDs.
- Public health is not giving sufficient priority to important global risk factors which are increasing over time, such as high blood pressure, high fasting glucose, high BMI, ambient particulate matter pollution and drug and alcohol use.
- There are many challenges resulting from the change in global population pyramid structures, which have become inverted over recent decades and now pose many health, financial and political challenges.

### Social determinants of health

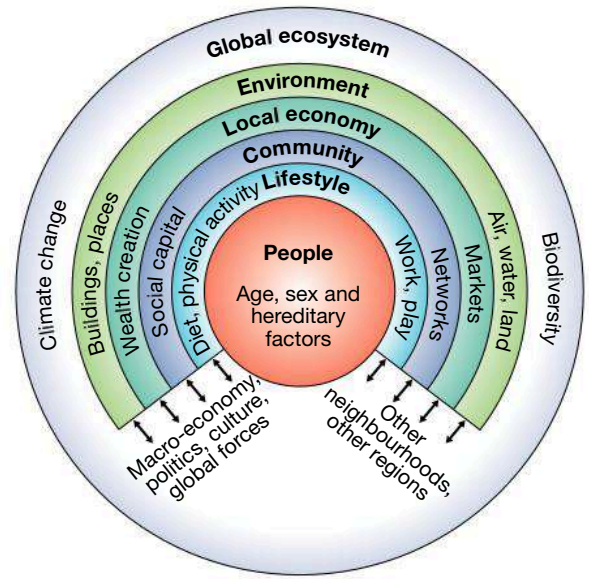

Health emerges from a highly complex interaction between a person's genetic background and environmental factors (aspects of the physical, biological (microbes), built and social environments and also distant influences such as the global ecosystem) (Fig. 5.1).

### The hierarchy of systems – from molecules to ecologies

Influences on health exist at many levels and extend beyond the individual to include the family, community, population and ecology. Box 5.4 shows an example of this for determinants of coronary heart disease and demonstrates the importance of considering not only the disease process in a patient but also its context. Health care is not the only determinant – and is usually not the major determinant – of health status in the population. The concept of 'global health' recognises the global dimension of health problems, whether these be, for example, emerging or pandemic infections or global economic influences on health internationally.

### The life course

The determinants of health operate over the whole lifespan. Values and behaviours acquired during childhood and adolescence have a profound influence on educational outcomes, job prospects and risk of disease. These can have a strong influence, for example, on whether a young person takes up a damaging behaviour like smoking, risky sexual activity and drug misuse. Influences on health can even operate before birth. Low birth weight can lead to higher risk hypertension and

**Fig. 5.1 Hierarchy of systems that influence population health.** Adapted from an original model by Whitehead M, Dahlgren G. *What can be done about inequalities in health? Lancet 1991; 338:1059–1063.*

### 5.4 'Hierarchy of systems' applied to ischaemic heart disease

Level in the hierarchy	Example of effect
Molecular	ApoB mutation causing hypercholesterolaemia
Cellular	Foam cells accumulate in vessel wall
Tissue	Atheroma and thrombosis of coronary artery
Organ	Ischaemia and infarction of myocardium
System	Cardiac failure
Person	Limited exercise capacity, impact on employment
Family	Passive smoking, diet
Community	Shops and leisure opportunities
Population	Prevalence of obesity
Society	Policies on smoking, screening for risk factors
Ecology	Agriculture influencing fat content in diet

type 2 diabetes in young adults and of cardiovascular disease in middle age. It has been suggested that under-nutrition during middle to late gestation permanently 'programmes' cardiovascular and metabolic responses.

This 'life course' perspective highlights the cumulative effect (through each stage of life) on health of exposures to illness, adverse environmental conditions and behaviours that damage health.

### Preventive medicine

The complexity of the interactions between physical, social and economic determinants of health means that successful prevention is often difficult. Moreover, the life course perspective illustrates that it may be necessary to intervene early in life or even before birth, to prevent important disease in later life. Successful prevention is likely to require many interventions across the life course and at several levels in the hierarchy of systems. The examples below illustrate this principle.

## Alcohol

Alcohol use is an increasingly important risk factor underlying global burden of disease (see [Box 5.3](#)). Reasons for increasing rates of alcohol-related harm vary by place and time but include the falling price of alcohol (in real terms), increased availability and cultural change fostering higher levels of consumption. Public, professional and governmental concern has now led to a minimum price being charged for a unit of alcohol, tightening of licensing regulations and curtailment of some promotional activity in many countries. However, even more aggressive public health measures will be needed to reverse the levels of harm in the population. The approach for individual patients suffering adverse effects of alcohol is described on pages 892 and 1240.

## Smoking

Smoking is also one of the top three risk factors underlying global burden of disease (see [Box 5.3](#)). It is responsible for a substantial majority of cases of lung cancer and chronic obstructive pulmonary disease (COPD), and most smokers die either from these respiratory diseases or from ischaemic heart disease. Smoking also causes cancers of the upper respiratory and gastrointestinal tracts, pancreas, bladder and kidney, and increases risks of peripheral vascular disease, stroke and peptic ulceration. Maternal smoking is an important cause of fetal growth retardation. Moreover, there is increasing evidence that passive ('second hand') smoking has adverse effects on cardiovascular and respiratory health.

The decline in smoking rates in many high-income countries has been achieved not only by warning people of the health risks but also increased taxation of tobacco, banning of advertising, banning of smoking in public places and support for smoking cessation to maintain a decline in smoking rates. However, smoking rates remain high in many poorer areas and are increasing amongst young women. In many low-income countries, tobacco companies have found new markets and rates are rising.

There is a complex hierarchy of systems that interact to cause smokers to initiate and maintain their habit. At the molecular and cellular levels, nicotine acts on the nervous system to create dependence and acts to maintain the smoking habit. There are also strong influences at the personal and social level, such as young female smokers being motivated to 'stay thin' or 'look cool' and peer pressure. Other important influences in the wider environment include cigarette advertising, with the advertising budget of the tobacco industry being much greater than that of health services. Strategies to help individuals quit smoking (such as nicotine replacement therapy, anti-smoking advice and behavioural support) are cost-effective and form an important part of the overall anti-tobacco strategy.

## Obesity

Obesity is an increasingly important risk factor underlying global burden of disease (see [Box 5.3](#)). The weight distribution of almost the whole population is shifting upwards – the slim are becoming less slim while the overweight and obese are becoming more so. In the UK, this translates into a 1-kilogram increase in weight per adult per year (on average over the adult population). The current obesity epidemic cannot be explained simply by individual behaviour and poor choice but also requires an understanding of the obesogenic environment that encourages people to eat more and exercise less. This includes the availability of cheap and heavily marketed energy-rich foods, the increase in labour-saving devices (e.g. elevators and remote controls) and the increase in passive transport (cars as opposed to walking, cycling, or walking to public transport hubs). To combat the health impact of obesity, therefore, we need to help those who are already obese but also develop strategies that impact on the whole population and reverse the obesogenic environment.

## Poverty and affluence

The adverse health and social consequences of poverty are well documented: high birth rates, high death rates and short life expectancy.

Typically, with industrialisation, the pattern changes: low birth rates, low death rates and longer life expectancy. Instead of infections, chronic conditions such as heart disease dominate in an older population. Adverse health consequences of excessive affluence are also becoming apparent. Despite experiencing sustained economic growth for the last 50 years, people in many high-income countries are not growing any happier and the litany of socioeconomic problems – crime, congestion, inequality, mental health problems – persists.

Many countries are now experiencing a 'double burden'. They have large populations still living in poverty who are suffering from problems such as diarrhoea and malnutrition, alongside affluent populations (often in cities) who suffer from chronic illness such as diabetes and heart disease.

## Atmospheric pollution

Emissions from industry, power plants and motor vehicles of sulphur oxides, nitrogen oxides, respirable particles and metals are severely polluting cities and towns in Asia, Africa, Latin America and Eastern Europe. Increased death rates from respiratory and cardiovascular disease occur in vulnerable adults, such as those with established respiratory disease and older people, while children experience an increase in bronchitic symptoms. Low-income countries also suffer high rates of respiratory disease as a result of indoor pollution caused mainly by heating and cooking combustion.

## Carbon dioxide and global warming

Climate change is arguably the world's most important environmental health issue. A combination of increased production of carbon dioxide and habitat destruction, both caused primarily by human activity, seems to be the main cause. The temperature of the globe is rising, climate is being affected, and if the trend continues, sea levels will rise and rainfall patterns will be altered so that both droughts and floods will become more common. These have already claimed millions of lives during the past 20 years and have adversely affected the lives of many more. The economic costs of property damage and the impact on agriculture, food supplies and prosperity have also been substantial. The health impacts of global warming will also include changes in the geographical range of some vector-borne infectious diseases. Currently, politicians cannot agree on an effective framework of actions to tackle the problem. Meanwhile, the industrialised world continues with lifestyles and levels of waste that are beyond the planet's ability to sustain.

## Principles of screening and immunisation

### Screening

Screening is the application of a screening test to a large number of asymptomatic people with the aim of reducing morbidity or mortality from a disease. WHO have identified a set of (Wilson and Jungner) criteria to guide health systems in deciding when it is appropriate to implement screening programmes. The essential criteria are:

- Is the disease an important public health problem?
- Is there a suitable screening test available?
- Is there a recognisable latent or early stage?
- Is there effective treatment for the disease at this stage which improves prognosis?

A suitable screening test is one that is cheap, acceptable, easy to perform, safe and gives a valid result in terms of sensitivity and specificity. Screening programmes should always be evaluated in trials so that robust evidence is provided in favour of their adoption. These evaluations are prone to several biases – self-selection bias, lead-time bias and length

bias – and these need to be accounted for in the analysis. Examples of large-scale screening programmes in the UK include breast, colorectal and cervical cancer national screening programmes (<https://www.gov.uk/topic/population-screening-programmes>) and a number of screening tests carried out in pregnancy and in the newborn, such as the:

- diabetic eye screening programme
- fetal anomaly screening programme
- infectious diseases in pregnancy screening programme
- newborn and infant physical examination screening programme
- newborn blood spot screening programme
- newborn hearing screening programme
- sickle-cell anaemia and thalassaemia screening programme.

These are illustrated in [Figure 5.2](#).

Problems with screening include:

- over-diagnosis (of a disease that would not have come to clinical attention on its own or would not have led to death)
- false reassurance
- diversion of resources from investments that could control the disease more cost-effectively.

## Immunisation

Immunisation can confer immunity to specific infectious diseases and be either passive (through injected antibodies, such as the monoclonal palivizimab against respiratory syncytial virus (RSV) infection given to premature infants) or active (through administration of a vaccine). Immunisation invokes antibody and/or cell-mediated immunity and can lead to both short- and longer-term protection in the person who is vaccinated. Immunisation has also been used to eradicate a disease such as occurred in the smallpox eradication programme and is currently being targeted in the polio eradication programme. As well as direct effects of vaccination a number of indirect effects can occur – such as protection of individuals who are vaccinated through altering disease transmission leading to ‘herd immunity’; or reduction of antibiotic resistance through selective reduction of pneumococcal serogroups that are associated with antibiotic resistance. The UK immunisation schedule is described in detail and regularly updated in the UK government publication ‘Immunisation against infectious disease’ (Green Book).

## Epidemiology

Epidemiologists study disease in free-living humans, seeking to describe patterns of health and disease and to understand how different exposures cause or prevent disease ([Box 5.5](#)). Chronic diseases and risk factors (e.g. smoking, obesity etc.) are often described in terms of their prevalence. A prevalence is simply a proportion, for example the prevalence of diabetes among people aged 80 and older in developed countries is around 10%.

Events such as deaths, hospitalisations and first occurrences of a disease are described using incidence rates, so, for example, if there are 100 new cases of a disease in a single year in a population of 1000, the incidence rate is 105 per 1000 person-years. The rate is 105 rather than 100 because the denominator is person-time, the sum of the total ‘exposed’ time for the population, which in this example is 950 person-years. Person-time is the sum of the total ‘exposed’ time for the population and in this example is 950 person-years. The reason the person-time is less than 1000 is that 100 people experienced the event. These 100 people are assumed to have had an event, on average, halfway through the time-period, removing 100 × 0.5 person-years from the exposure-time (as it is not possible to have a first occurrence of a disease twice).

A similar measure to the incidence rate is the cumulative incidence or risk, which is the number of new cases as a proportion of the total people at risk at the beginning of the exposure time. If in the example above the same 1000 people were observed for a year (i.e. with no one joining or leaving the group) then the one-year risk is 10% (100/1000). The time-period should always be specified for risks.

These rates and proportions are used to describe how diseases (and risk factors) vary according to time, person and place. Temporal variation may occur seasonally; for example, malaria occurs in the wet season but not the dry, or as longer-term ‘secular’ trends, e.g. malaria may re-emerge due to drug resistance. Person comparisons include age, sex, socio-economic status, employment, and lifestyle characteristics. Place comparisons include the local environment (e.g. urban versus rural) and international comparisons.

## Understanding causes and effect

Epidemiological research complements that based on animal, cell and tissue models, the findings of which do not always translate to humans. For example, only a minority of drug discoveries from laboratory research are found to be effective when tested in people.

However, differentiating causes from mere non-causal associations is a considerable challenge for epidemiology. This is because while laboratory researchers can directly manipulate conditions to isolate and understand causes, such approaches are impossible in free-living populations. Epidemiologists have developed a different approach, based around a number of study designs ([Box 5.6](#)). Of these, the clinical trial is closest to the laboratory experiment. An early example of a clinical trial is shown in [Figure 5.3](#), along with ‘effect measures’ which are used to quantify the difference in rates and risks.

In clinical trials, patients are usually randomly allocated to treatments so that, on average, groups are similar apart from the intervention of interest. Nevertheless, for any particular trial, especially a small trial, the laws of probability mean that differences can and do occur by chance. Poorly designed or executed trials can also limit comparability between groups. Allocation may not truly be random (e.g. because of inadequate concealment of the randomisation sequence), and there may be systematic differences (biases) in the way people allocated to different groups are treated or studied.

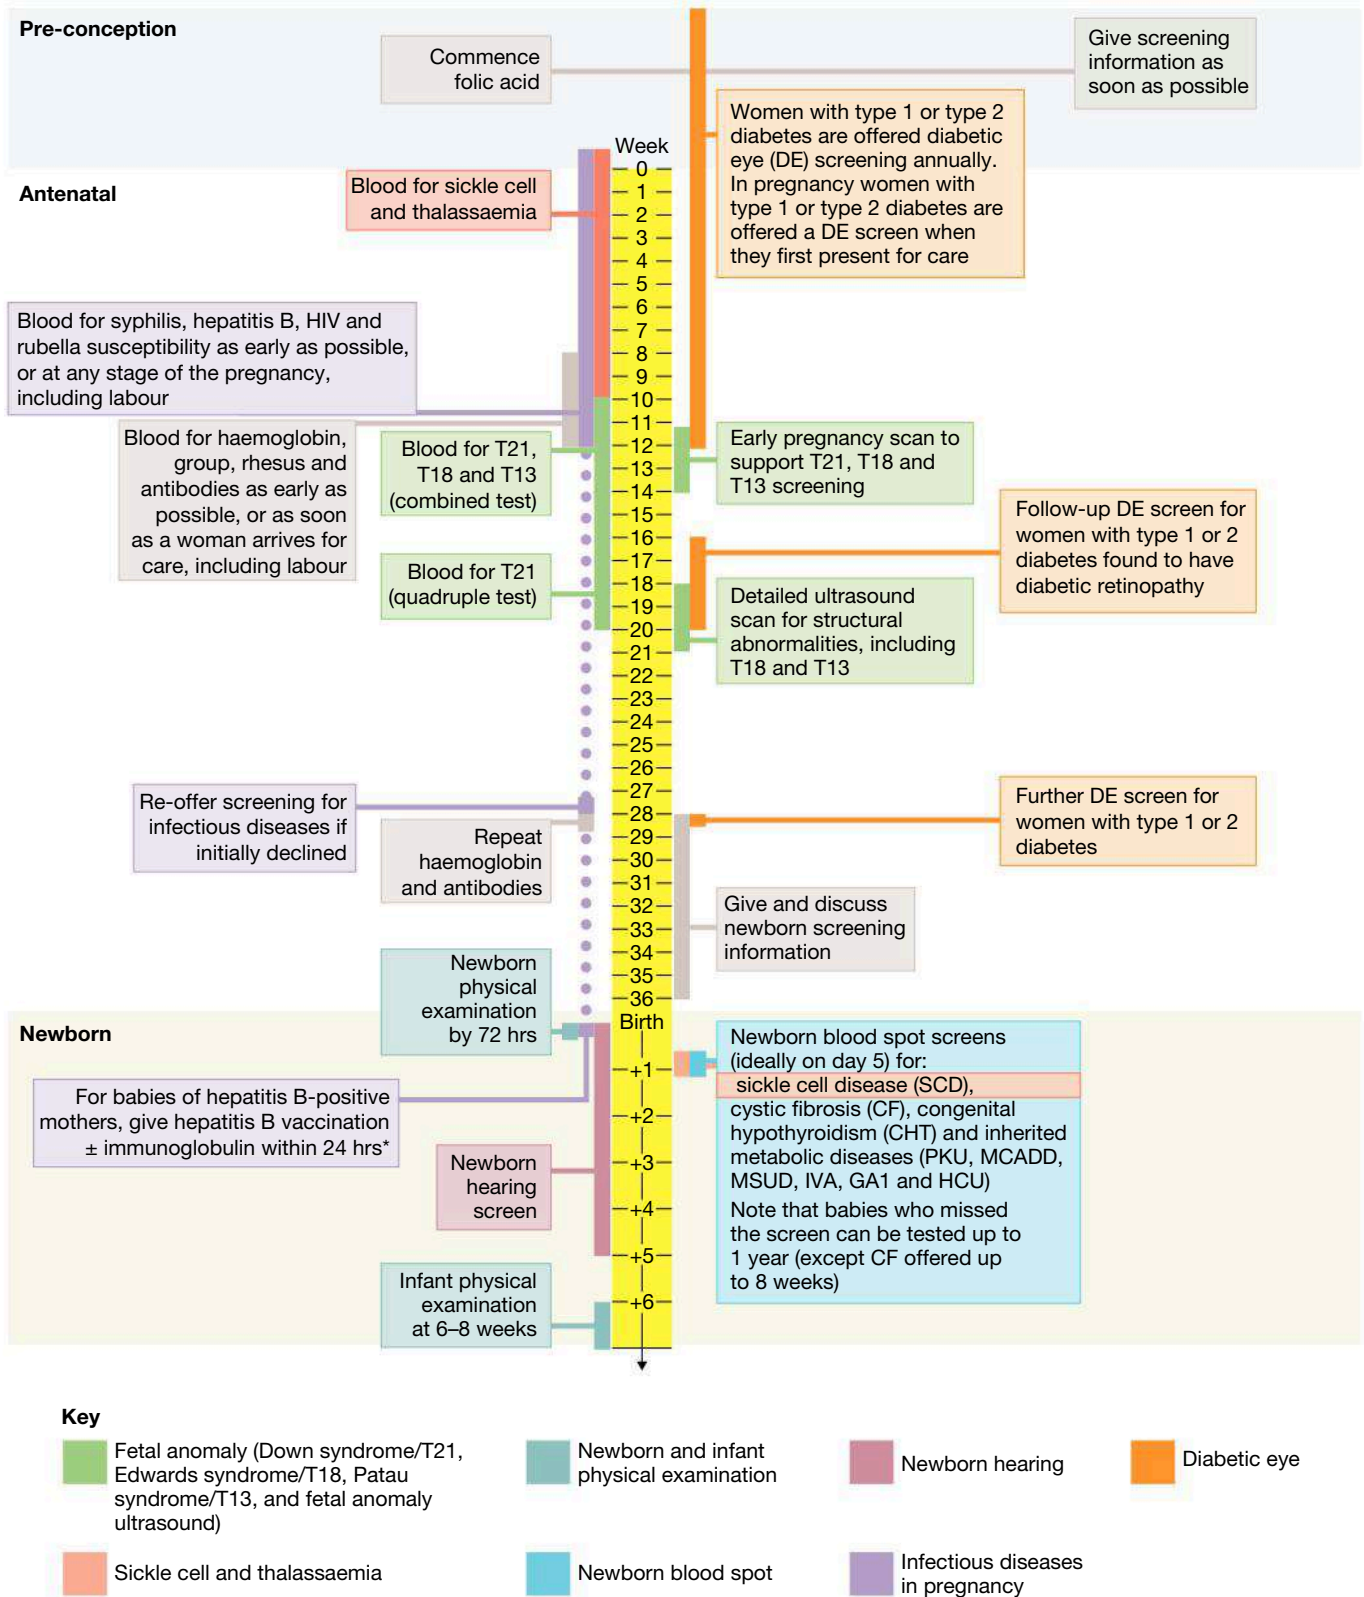

Such biases also occur in observational epidemiological study designs, such as cohort, case-control and cross-sectional studies (see [Box 5.6](#)). These designs are also much more subject to the problem of confounding than are randomised trials.

Confounding is where the relationship between an exposure and outcome of interest is confused by the presence of some other causal factor. For example, coffee consumption may be associated with lung cancer because smoking is commoner among coffee-drinkers. Here, smoking is said to confound the association between coffee and lung cancer.

Despite these limitations, for most causes of diseases, randomised controlled trials are not feasible because of ethical, or more often practical, considerations. Epidemiologists therefore seek to minimise bias and confounding by good study design and analysis. Epidemiologists subsequently make causal inferences by balancing the probability that an observed association has been caused by chance, bias and/or confounding against the alternative probability that the relationship is causal. This weighing-up requires an understanding of the frequency and importance of different sources of bias and confounding as well as the scientific rationale of the putative causal relationship. It was this approach, collectively and over a number of years, that settled the fact that smoking causes lung cancer, and, subsequently, heart disease.

## Mendelian randomisation

Mendelian randomisation (MR) is a method to study whether the relationship between a (modifiable) risk factor and a disease may be causal. It uses genetic variation in a gene that influences the level of the risk factor under consideration and studies the impact of this variation on

**Fig. 5.2 UK NHS pregnancy and newborn screening programmes.** Antenatal and newborn screening timeline. \*To stop mother-to-baby transmission of infection follow up all infection screens in pregnancy that are positive: carry out paediatric assessment and follow-up of mothers who are found to be HIV-positive or had syphilis treatment in pregnancy; and if mothers are found to be susceptible to rubella then offer the mother MMR vaccination postnatally and refer to GP for second dose. (GA1 = glutaric aciduria type 1; HCU = homocystinuria; IVA = isovaleric acidemia; MCADD = medium-chain acyl-CoA dehydrogenase deficiency; MSUD = maple syrup urine deficiency; PKU = phenylketonuria) Based on Version 8.4, January 2019. Gateway Ref: 20144696. [www.gov.uk/phe/screening](http://www.gov.uk/phe/screening).

## 5.5 Calculation of risk using descriptive epidemiology

### Prevalence

- The ratio of the number of people with a longer-term disease or condition at a specified time, to the number of people in the population who are at risk

### Incidence

- The number of events (new cases or episodes) occurring in the population at risk during a defined period of time

### Attributable risk

- The difference between the risk (or incidence) of disease in exposed and non-exposed populations

### Attributable fraction

- The ratio of the attributable risk to the incidence

### Relative risk

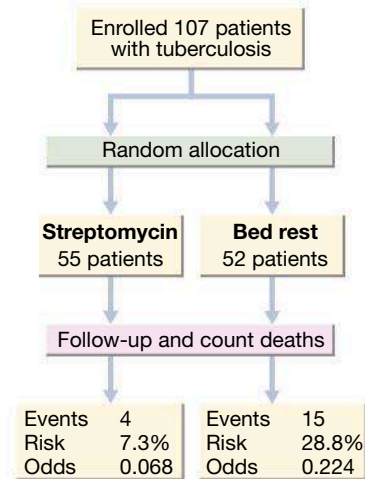

- The ratio of the risk (or incidence) in the exposed population to the risk (or incidence) in the non-exposed population

## 5.6 Epidemiological study designs

Design	Description	Example
Clinical trial	Enrols a sample from a population and compares outcomes after randomly allocating patients to an intervention	The Medical Research Council (MRC) streptomycin trial – demonstrated effectiveness of streptomycin in tuberculosis
Cohort	Enrols a sample from a population and compares outcomes according to exposures	The Framingham Study – identified risk factors for cardiovascular disease
Case-control	Enrols cases with an outcome of interest and controls without that outcome, and compares exposures between the groups	Doll and Hill's study on smoking and carcinoma of the lung (BMJ 1950, 2) demonstrated that smoking caused lung cancer
Cross-sectional	Enrols a cross-section (sample) of people from the population of interest. Obtains data on exposures and outcomes	World Health Organization Demographic and Health Survey. Captures risk factor data in a uniform way across many countries

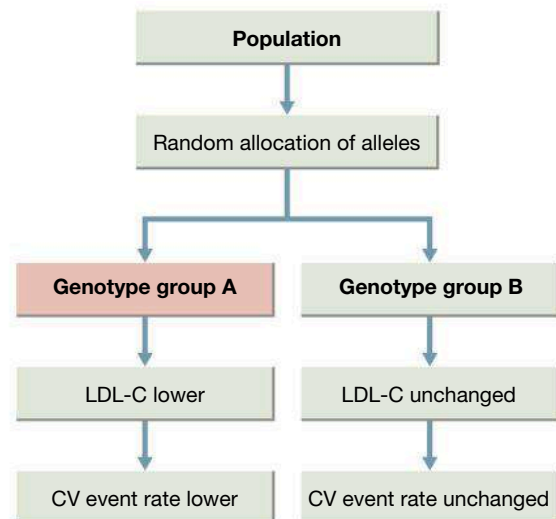

disease risk (see Fig. 5.4 for an example). The genetic variant (or multiple variants or genetic risk score) is used as an instrumental variable under certain assumptions. MR investigates the effect of differences in the risk factor level through the life course which have been determined by the genetic variants. This approach uses observational data to test a proposed causal relationship and to estimate the size of effect. Guidelines such as STROBE-MR have been published for the proper conduct of these studies and analytic software packages are now available which contain a range of methods and tools. The selection of the most appropriate method depends on the research question and the data structure.

The MR approach requires very large sample sizes to have sufficient power and very large databases of genetic and health data such as UK Biobank are often used. MR can be conducted using either individual level data or summary data from genome-wide association studies (GWAS); and data from one study (one sample) or two studies with the variant-risk factor association measure from one and the risk factor-outcome association from the other (two sample).

Effect measures	
Risk ratio (relative risk, RR)	0.25
Odds ratio (OR)	0.30
Absolute risk reduction (ARR)	21.6%
Relative risk reduction (RRR)	74.8%
Number needed to treat to prevent one death (NNT= 1/ARR)	4.6

**Fig. 5.3** An example of a clinical trial: streptomycin versus bed rest in tuberculosis. Both prevalences and risks are, in fact, proportions and are therefore frequently expressed as odds. The reasons for doing so are beyond the scope of this text.

**Fig. 5.4** Mendelian randomisation. An example showing comparison of a conventional trial with a Mendelian randomisation study. (CV = cardiovascular; LDL-C = low-density lipoprotein cholesterol) Adapted with permission from Bennett DA, Holmes MV. *Heart* 2017; 103:1400–1407.

Correct interpretation of MR results is challenging and multiple analytic methods are often employed. This includes methods to detect and adjust for pleiotropy (having more than one effect) which is a common problem in data interpretation. The strength of the conclusions depends on the degree to which instrumental variable assumptions are met and the level of consistency of findings across different methods. MR has proven useful in both identifying new causal relationships or confirming trial results but also in redirecting research interest away from relationships that have been shown not to be causal. MR can be considered

INTERNATIONAL FORM OF MEDICAL CERTIFICATE OF CAUSE OF DEATH		
	Cause of death	Approximate interval between onset and death
<b>I</b> Disease or condition directly leading to death*	(a) <i>Acute myocardial infarction</i> <b>I21.9</b>	<i>2 days</i>
	due to (or as a consequence of)	
	(b) <i>Familial hypercholesterolaemia</i> <b>E78.0</b>	<i>30 years</i>
	due to (or as a consequence of)	
<b>Antecedent causes</b> Morbid conditions, if any, giving rise to the above cause, stating the underlying condition last	(c) .....	.....
	due to (or as a consequence of)	
	(d) .....	.....
	due to (or as a consequence of)	
<b>II</b> Other significant conditions contributing to the death, but not related to the disease or condition causing it	<i>Bronchiectasis</i> <b>J47</b>	<i>10 years</i>
	.....	.....

*\*This does not mean the mode of dying, e.g. heart failure, respiratory failure. It means the disease, injury, or complication that caused death.*

**Fig. 5.5 Completed death certificate.** International Classification of Diseases 10 (ICD-10) codes are appended in red. Based on World Health Organization, ICD-10, vol. 2. Geneva: WHO; 1990. Form retrieved from [https://commons.m.wikimedia.org/wiki/File:International\\_form\\_of\\_medical\\_certificate\\_of\\_cause\\_of\\_death.png](https://commons.m.wikimedia.org/wiki/File:International_form_of_medical_certificate_of_cause_of_death.png).

to provide further evidence for or against a causal relationship but care should be taken in interpretation of the size of the expected impact from an intervention.

## Health data/informatics

As patients pass through health and social care systems, data are recorded concerning their family background, lifestyle and disease states, which is of potential interest to health-care organisations seeking to deliver services, policy-makers concerned with improving health, scientific researchers seeking to understand health, and also to pharmaceutical and other commercial organisations seeking to identify markets.

There is a long tradition of maintaining health information systems. In most countries, the registration of births and deaths is required by law, and in the majority, the cause of death is also recorded (Fig. 5.5). There are numerous challenges in ensuring such data are useful, especially for making comparisons across time and place. First, a system of standard terminologies is needed, such as the World Health Organization International Classification of diseases, which provides a list of diagnostic codes attempting to cover every diagnostic entity. Secondly, these terms must be understood to refer to the same, or at least similar diseases in different places. Thirdly, access to diagnostic skill and facilities is required, fourthly standard protocols for assigning clinical diagnoses to ICD-10 codes are needed and fifthly, robust quality control processes are needed to maintain some level of data completeness and accuracy.

Many countries employ similar systems for hospitalisations, either to allow recovery of healthcare utilisation costs, or to manage and plan services. Similar data are, however, rarely collected for community-based healthcare. Nor are detailed data on health-care process generally included in national data systems.

Consequently, there has been considerable interest in using data from information technology systems used to deliver care – such as electronic patient records, drug-dispensing databases, radiological software, and clinical laboratory information systems.

Data from such systems are, of course, much less structured than those obtained from vital registrations. Moreover, the completeness of such data depends greatly on local patterns of healthcare utilisation as well as how clinicians and others use IT systems within different settings. As such, deriving useful unbiased information from such data is a considerable challenge.

Much of the discipline of health informatics is concerned with addressing this challenge. One approach has been to develop comprehensive standard classification systems such as SNOMED-CT ‘a standardised, multilingual vocabulary of terms relating to the care of the individual’ which has been designed for electronic health-care records. An alternative has been to use statistical methods such as natural language processing to automatically derive information from free text (such as culling diagnoses from radiological reports), or to employ ‘machine learning’, in which software algorithms are applied to data in order to derive useful insights. Such approaches are suited to large, messy data where the costs of systematisation would be prohibitive. It is likely that such innovations will over the coming years provide useful information to complement that obtained from more traditional health information systems.

## Management of epidemics

An epidemic, as defined by the World Health Organization, occurs when 'in a community or region [the] cases of an illness, specific health-related behaviour, or other health-related events [are] clearly in excess of normal expectancy'. Epidemics that are small-scale or confined to a small geographic area are informally referred to as 'outbreaks'.

Epidemics are regularly caused where preventative measures break down; examples include breaches of food safety procedures in restaurants resulting in outbreaks of enteropathogenic *E. coli* infection, failure to adequately maintain cooling towers causing *Legionella* infections and falls in vaccination coverage resulting in measles epidemics.

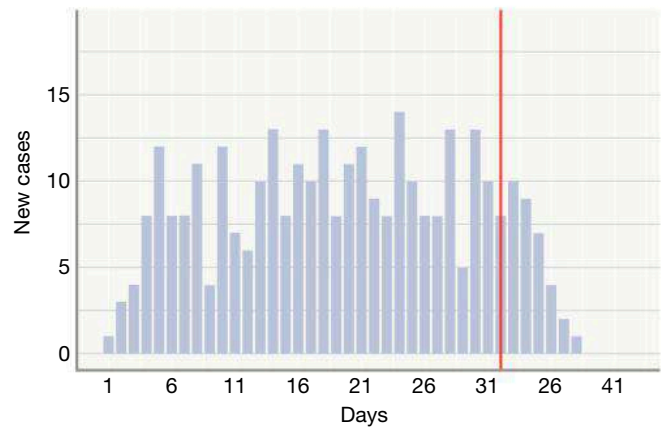

Epidemics can also arise from novel infectious agents such as the SARS-CoV-1, MERS, SARS-CoV-2 and H1N1 viruses, for which new preventative measures require to be developed. Where epidemics from novel agents are not controlled locally, but instead spread beyond international borders, these are termed pandemics, of which SARS-CoV-2 and H1N1 are examples.

To detect epidemics early, public health agencies undertake surveillance. Surveillance involves the collection and review of cases that have been identified via statutory notifications, or health information systems (such as microbiology reporting systems). For some infections such as *E. coli* and *Legionella*, one challenge for public health agencies is to distinguish epidemics from 'sporadic' cases at an early stage. This is done using human judgement, for example, if a large number of cases of *E. coli* occur in individuals who ate a specific food, although this task is sometimes supported using computer algorithms.

Epidemics require an incident management team, some of whose members have legal powers to impose measures to control infection. The team establish a formal case definition for confirmed, probable and possible cases (based on epidemiological features as well as clinical and/or microbiological findings), interview individuals with whom cases have had significant contact (termed contact tracing), test potential sources of infections (e.g. foodstuffs or industrial cooling towers), and implement control measures. The latter might include requiring infected individuals to isolate for a time period (e.g. until they are asymptomatic or until they test negative depending on the infectious agent), and/or ordering temporary closure of businesses thought to be sources of infection (e.g. a restaurant with poor food hygiene practices).

Epidemic curves are crucial to the monitoring and management of epidemics. Figure 5.6 shows a notional epidemic curve for an epidemic caused by a single source, which is eliminated after 31 days. However, they are also used in more complex epidemics where there is person-to-person spread. In the latter, epidemic curves are used to estimate key statistics such as the basic reproduction number (R0) in the population, as well as to make projections about future infections. Where the source of an epidemic is not apparent, comparative epidemiological methods can be used to identify the likely source, for example, a case-control design may identify a higher than expected consumption of a given food – for example uncooked legumes – among cases compared to controls prompting testing of foods, an education campaign and/or product recalls.

The principles for managing pandemics are similar to those for managing epidemics but operate on a national or international scale. The universality of pandemics, however, means that they pose special problems. First, they pose risks to the society-wide infrastructure needed to deal with diseases, including, but not limited to health-care facilities. Secondly, pandemics, unlike local and regional epidemics are rare, so

**Fig. 5.6** Epidemic curve for a notional outbreak within a single ongoing source. Red line indicates time point where source of infection was removed (e.g. closure of a restaurant).

agencies have little direct experience with their management. For this reason, most settings develop pandemic plans and undertake regular table-top simulations to test and improve their preparedness. The COVID-19 pandemic, caused by SARS-CoV-2, is a key example and is discussed in detail in Chapter 13.

## Multiple Choice Questions

5.1. Which of the following are examples of large-scale screening programmes across all of the UK in 2021?

- A. Cervical cancer national screening programme in women
- B. Prostate cancer national screening programme in men
- C. Diabetic eye screening programme in both men and women
- D. Newborn hearing screening programme
- E. Abdominal aortic aneurysm screening programme in both men and women

Answer: A, C and D.

Prostate cancer screening has not proven to be cost-effective and thus is not approved by the UK National Screening Committee. An abdominal aortic aneurysm screening programme operates only in men 65 years of age or over but not in women.

5.2. Which of the following statements describe the current newborn blood spot screening programme in the UK?

- A. Ideally, blood spots should be collected on day 14
- B. Babies who missed the screen can be tested up to 1 month of age
- C. Blood spots are screened for sickle-cell disease
- D. Blood spots are screened for cystic fibrosis
- E. Blood spots are screened for congenital hypothyroidism

Answer: C, D and E.

Ideally, blood spots should be collected on day 5. Babies who missed the screen can be tested up to 1 year of age. Newborn blood spot screens for: sickle-cell disease, cystic fibrosis, congenital hypothyroidism and inherited metabolic diseases (PKU, MCADD, MSUD, IVA, GA1 and HCU – see [Fig. 5.2](#)).

Antiparasitic agents 124

'Infection' in its strict sense describes the situation where microorganisms or other infectious agents become established in the host organism's cells or tissues, replicate, induce a host response, and result in pathologic changes in tissues. If a microorganism survives and replicates on an epithelial surface without causing pathological change the host is said to be 'colonised' by that organism. If a microorganism survives and lies dormant after invading host cells or tissues, infection is said to be 'latent'. When a microorganism, or the host response to it, is sufficient to cause illness or harm, then the process is said to have caused infection, which may manifest by symptoms or signs. In milder cases there can be asymptomatic infection that may be identified by detection of a pathogen or the host response to the pathogen. Most pathogens (agents that can cause infection) are microorganisms but some are multicellular organisms. The manifestations of disease may aid pathogen dissemination (e.g. diarrhoea or coughing).

The term 'infection' is often used interchangeably with 'infectious disease' but not all infections are 'infectious', i.e. transmissible from person to person, and not all infections result in symptomatic disease. Infectious diseases caused by pathogens that are transmitted between hosts can also be called 'communicable diseases', whereas infection caused by organisms that are already colonising the host are described as 'endogenous'. The distinction is blurred in some situations, including health care-associated infections such as methicillin-resistant *Staphylococcus aureus* (MRSA) or *Clostridioides* (formerly *Clostridium*) *difficile* infection (CDI), in which colonisation precedes infection but the colonising bacteria may have been recently transmitted between patients. The chain of infection (Fig. 6.1) describes elements for communicable disease transmission.

Despite dramatic advances in hygiene, immunisation and antimicrobial therapy, infections still cause a massive burden of disease worldwide.

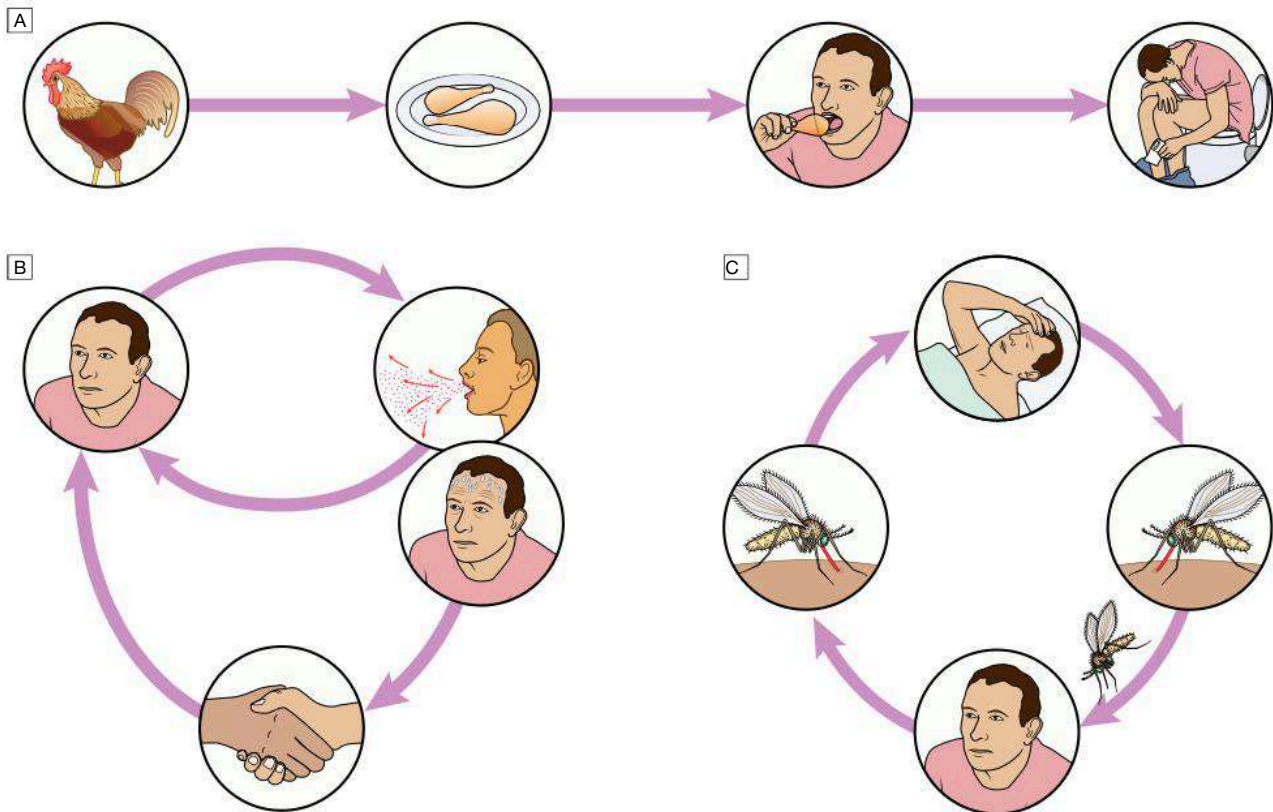

Key challenges remain in tackling infection in resource-poor countries. Microorganisms are continually mutating and evolving; the emergence of new infectious agents (e.g. SARS-CoV-2, see Ch. 13) and antimicrobial-resistant microorganisms is therefore inevitable. This chapter describes the biological and epidemiological principles of infectious diseases and the general approach to their prevention, diagnosis and treatment. Specific infectious diseases are described in Chapters 13–15 and many of the organ-based chapters.

## Agents causing infection

The concept of an infectious agent was established by Robert Koch in the 19th century (Box 6.1). Although fulfilment of 'Koch's postulates' became the standard for confirming the cause of an infection, many infectious agents do not fulfil Koch's postulates (e.g. uncultivable organisms and the causes of endogenous infections), and the postulates are now of mainly historical interest. The groups of infectious agents that are now recognised are described in the following sections.

### 6.1 Definition of an infectious agent – Koch's postulates

1. The same organism must be present in every case of the disease.
2. The organism must be isolated from the diseased host and grown in pure culture.
3. The isolate must cause the disease, when inoculated into a healthy, susceptible animal.
4. The organism must be re-isolated from the inoculated, diseased animal.

**Fig. 6.1** The chain of infection can be linear (A) and cyclical (B and C). **A** Infections with an animal reservoir (e.g. *Campylobacter* enteritis) require a portal of exit from the reservoir and a vehicle for transmission to a susceptible human host (often water or a contaminated item of food). **B** Infections with person-to-person transmission (e.g. respiratory virus infection) require a mode of exit from the infected person, a mode of transmission (e.g. contaminated respiratory droplets or transmission via the surface of an intermediate fomite) and a portal of entry to a susceptible host. **C** Infections with an insect vector (e.g. malaria) require a mode of transmission from the insect reservoir to a susceptible human host and a mode of transmission back to the insect vector. Many infections involve a combination of these modes of transmission (e.g. Lyme disease, which has both an animal host and an insect vector) or several different modes of transmission.

**Fig. 6.2 A generic virus life cycle.** Life cycle components common to most viruses are host cell attachment and penetration, virus uncoating, nucleic acid and protein synthesis, virus assembly and release. Virus release is achieved either by budding, as illustrated, or by lysis of the cell membrane. Life cycles vary between viruses.

## Viruses

Viruses are incapable of independent replication. Instead, they subvert host cellular processes to ensure synthesis of their nucleic acids and proteins. Viruses' genetic material (the genome) consists of single- or double-stranded DNA or RNA. Retroviruses transcribe their RNA into DNA in the host cell by reverse transcription. An antigenically unique protein coat (capsid) encloses the genome, and together these form the nucleocapsid. In many viruses, the nucleocapsid is packaged within a lipid envelope. Enveloped viruses are less able to survive in the environment and are spread by respiratory, sexual or blood-borne routes, including arthropod-based transmission. Non-enveloped viruses survive better in the environment and are predominantly transmitted by faecal-oral or, less often, respiratory routes. A generic virus life cycle is shown in Figure 6.2. A virus that infects a bacterium is a bacteriophage (phage).

## Prokaryotes: bacteria (including mycobacteria and actinomycetes)

Prokaryotic cells can synthesise their own proteins and nucleic acids, and are able to reproduce autonomously, although they lack a nucleus. The bacterial cell membrane is bounded by a peptidoglycan cell wall, which is thick (20–80nm) in Gram-positive organisms and thin (5–10nm) in Gram-negative ones. The Gram-negative cell wall is surrounded by an outer membrane containing lipopolysaccharide. Genetic information is contained within a chromosome but bacteria may also contain rings of extra-chromosomal DNA, known as plasmids, which can be transferred between organisms, without cells having to divide. Bacteria may be embedded in a polysaccharide capsule, and motile bacteria are equipped with flagella. Although many prokaryotes are capable of independent existence, some (e.g. *Chlamydia trachomatis*, *Coxiella burnetii*) are obligate intracellular organisms. Bacteria that can grow in artificial culture media are classified and identified using a range of characteristics (Box 6.2); examples are shown in Figures 6.3 and 6.4.

## Eukaryotes: fungi, protozoa and helminths

Eukaryotic cells contain membrane-bound organelles, including nuclei, mitochondria and Golgi apparatus. Pathogenic eukaryotes are unicellular (e.g. yeasts, protozoa) or complex multicellular organisms (e.g. nematodes, trematodes and cestodes).

## i

### 6.2 How bacteria are identified

#### Gram stain reaction (see Fig. 6.3)

- Gram-positive (thick peptidoglycan layer), Gram-negative (thin peptidoglycan) or unstainable

#### Microscopic morphology

- Cocci (round cells) or bacilli (elongated cells)
- Presence or absence of capsule

#### Cell association

- Association in clusters, chains or pairs

#### Colonial characteristics

- Colony size, shape or colour
- Effect on culture media (e.g.  $\beta$ -haemolysis of blood agar in haemolytic streptococci; see Fig. 6.4)

#### Atmospheric requirements

- Strictly aerobic (requires  $O_2$ ), strictly anaerobic (requires absence of  $O_2$ ), facultatively aerobic (grows with or without  $O_2$ ) or micro-aerophilic (requires reduced  $O_2$ )

#### Biochemical reactions

- Expression of enzymes (oxidase, catalase, coagulase)
- Ability to ferment or hydrolyse various biochemical substrates

#### Motility

- Motile or non-motile

#### Antibiotic susceptibility

- Identifies organisms with invariable susceptibility (e.g. to optochin in *Streptococcus pneumoniae* or metronidazole in obligate anaerobes)

#### Matrix-assisted laser desorption/ionisation time-of-flight mass spectrometry (MALDI-TOF-MS)

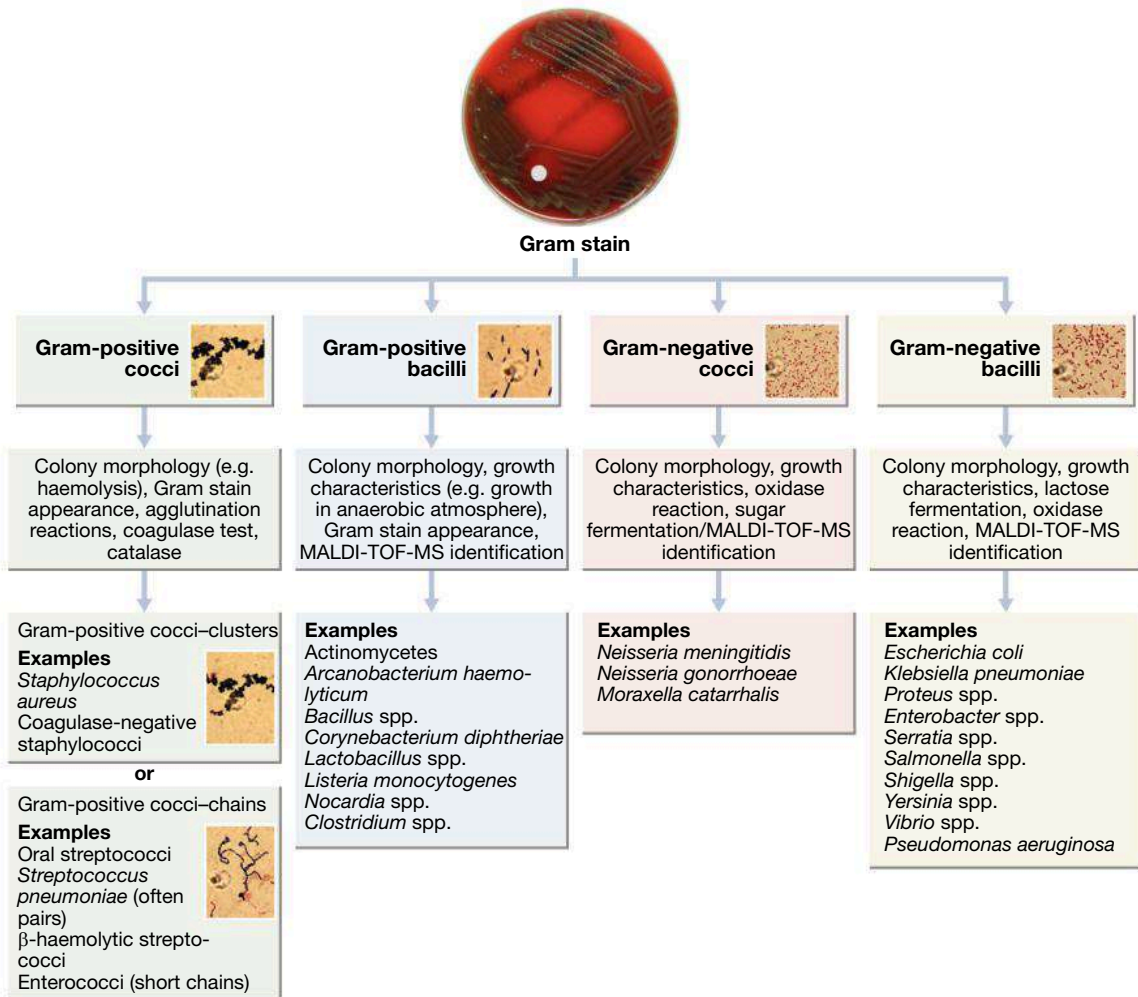

- A rapid technique that identifies bacteria and some fungi from their specific molecular composition

#### Sequencing bacterial 16S ribosomal RNA gene

- A highly specific test for identification of organisms in pure culture and in samples from normally sterile sites

#### Whole-genome sequencing

- Although not yet in routine use, whole-genome sequencing (WGS) offers the potential to provide rapid and simultaneous identification, sensitivity testing and typing of organisms from pure culture and/or directly from clinical samples. As such, WGS is likely to replace many of the technologies described above over the next few years

**Fig. 6.3** Flow chart for bacterial identification, including Gram film appearances on light microscopy ( $\times 100$ ). (MALDI-TOF-MS = matrix-assisted laser desorption/ionisation time-of-flight mass spectroscopy).

**Fig. 6.4**  $\beta$ -haemolytic streptococci (A) and  $\alpha$ -haemolytic streptococci (B) spread on each half of a blood agar plate (backlit). This image is half life-size.  $\times 0.5$ .  $\beta$ -haemolysis renders the agar transparent around the colonies (A) and  $\alpha$ -haemolysis imparts a green tinge to the agar (B).

Fungi exist as either moulds (filamentous fungi) or yeasts. Dimorphic fungi exist in either form, depending on environmental conditions (see Fig. 13.62). The fungal plasma membrane differs from the human cell membrane in that it contains the sterol, ergosterol. Fungi have a cell wall made up of polysaccharides, chitin and mannoproteins. In most fungi, the main structural component of the cell wall is  $\beta$ -1,3-D-glucan, a polysaccharide. These differences from mammalian cells are important because they offer useful therapeutic targets.

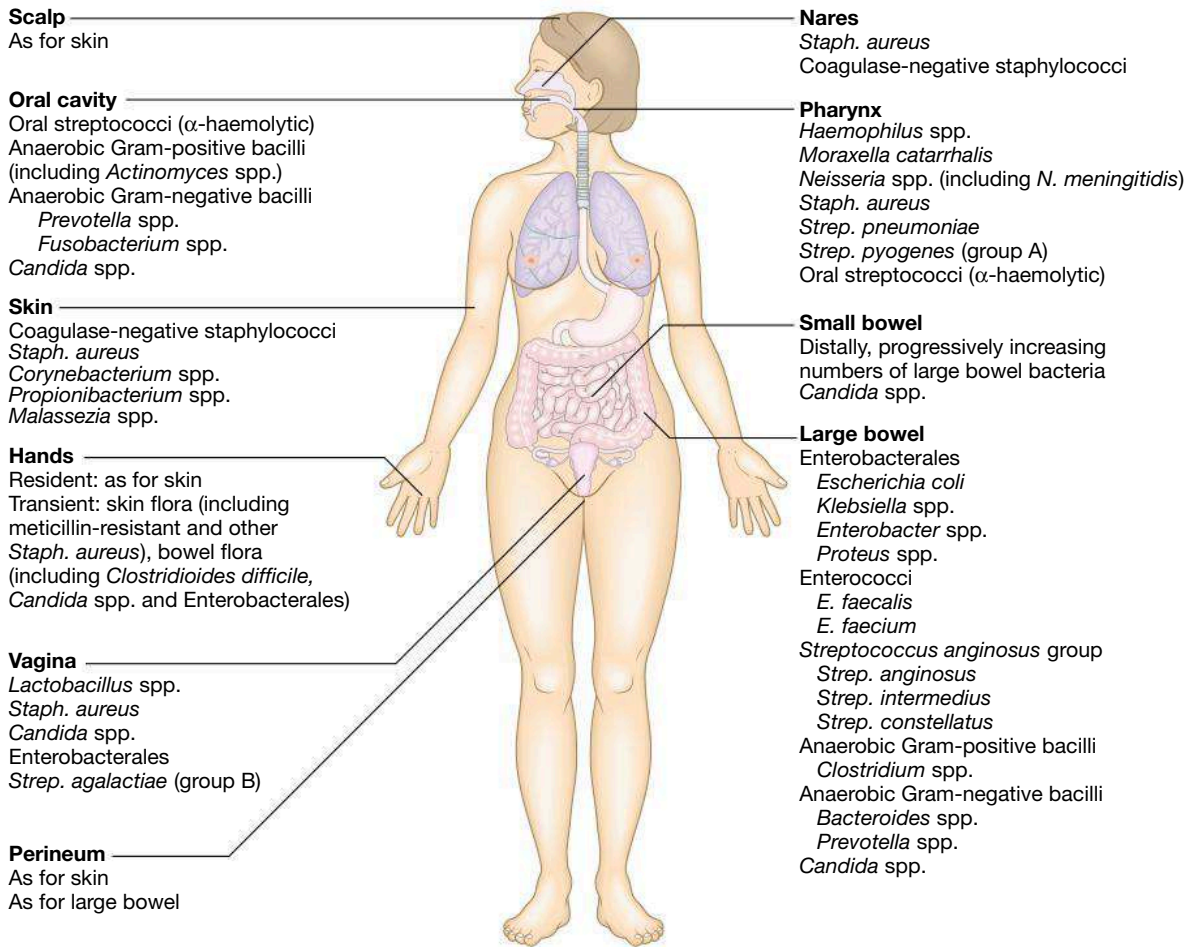

Protozoa and helminths are often referred to as parasites. Many parasites have complex multistage life cycles, which involve animal and/or plant hosts in addition to humans.

### Prions

Although prions are transmissible and have some of the characteristics of infectious agents, they are not microorganisms, and are discussed on page 1181.

### Normal microbial flora

The human body is colonised by large numbers of microorganisms (collectively termed the human microbiota). Colonising bacteria, also referred to as the 'normal bacterial flora', are able to survive and replicate on epithelial

**Fig. 6.5** Human non-sterile sites and normal flora in health.

surfaces, e.g. skin and mucosal surfaces. The gastrointestinal tract and the mouth are the two most heavily colonised sites in the body and they have distinct microbiota, in both composition and function. Knowledge of non-sterile body sites and their normal bacterial flora is required to inform microbiological sampling strategies and interpret culture results (Fig. 6.5).

The microbiota is the total burden of microorganisms, their genes and their environmental interactions, and is now recognised to have a profound influence on human health and disease. Maintenance of the normal flora is beneficial to normal immune function. Other functions include: lower gastrointestinal tract bacteria synthesise and excrete vitamins (e.g. vitamins K and B<sub>12</sub>); colonisation with normal flora confers ‘colonisation resistance’ to infection with pathogenic organisms by altering the local environment (e.g. lowering pH), producing antibacterial agents (e.g. bacteriocins (small antimicrobial peptides/proteins), fatty acids and metabolic waste products), and inducing host antibodies that cross-react with pathogenic organisms.

Conversely, some body sites are either sterile or contain very low numbers of colonising bacteria. For example, the submucosal tissues, blood stream, peritoneal and pleural cavities are maintained as sterile by physical separation from the external environment; and the lower airways and bladder, sites that were formerly believed to be sterile but are now known to support limited microbiota, are protected from excessive contamination by the mucociliary escalator and urethral sphincter respectively, as well as local immune responses.

Members of the normal flora can cause (endogenous) infection by ‘translocation’ from their normal habitat to other body sites or by excessive growth at the ‘normal’ site (overgrowth). Overgrowth is exemplified by dental caries and ‘blind loop’ syndrome (p. 821). Translocation results from spread along a surface or penetration through a colonised surface, e.g. urinary tract infection caused by perineal/enteric flora, and surgical

site infections, particularly of prosthetic materials, caused by skin flora such as staphylococci. Normal flora also contribute to disease by cross-infection; organisms colonising one individual can cause disease when transferred to another, more susceptible, individual.

The importance of limiting antimicrobial-induced perturbations of microbiota is increasingly recognised. ‘Probiotics’ are proprietary microbes or mixtures of microbes administered with the aim of restoring a beneficial profile of gastrointestinal normal flora. Faecal microflora transplantation (FMT) has the same aim, by giving gastrointestinal microbiota from healthy people (filtered extract of faeces) to a patient. Although the clinical effectiveness of probiotics remains a subject of debate, FMT has proven benefit in recurrent *C. difficile* infection.

## Host–pathogen interactions

A ‘pathogen’ is a microorganism that can cause infection. The manifestations of infection, including a pathogen’s ability to cause severe disease in a previously healthy host, are affected by its ‘virulence’. Virulence is determined by the number and type of disease-causing proteins and other factors that it can produce (‘virulence factors’).

- *Primary pathogens* cause disease in a proportion of individuals to whom they are exposed, regardless of the host’s immunological status.
- *Opportunistic pathogens* cause disease only in individuals whose host defences are compromised, e.g. by an intravascular catheter, or when the immune system is compromised, by genetic susceptibility or immunosuppressive therapy.

## Determinants of virulence

For a primary pathogen to cause infection in a healthy host it must compete with colonising flora to reach target host cells. It can do this in various ways, including sequestration of nutrients, adapting metabolism to exploit metabolites not used by commensal flora, production of bacteriocins, and using motility to 'swim' to the site of infection. Many microorganisms, including viruses, use 'adhesins' to initiate their attachment to host cells. Some pathogens can invade through tissues. Many bacteria and fungi multiply after initial adhesion to a host surface to form 'biofilms'. These are complex three-dimensional structures surrounded by a matrix of host and bacterial products, which afford protection to the colony and limit the effectiveness of antimicrobials. Biofilm-related infections on man-made medical devices such as vascular catheters or grafts can be particularly difficult to treat.

Pathogens may produce toxins, microbial molecules that cause adverse effects on host cells, either at the site of infection, or remotely following carriage through the blood stream. Endotoxin is the lipid component of Gram-negative bacterial outer membrane lipopolysaccharide. It is released when bacterial cells are damaged and has generalised inflammatory effects. Exotoxins are proteins released by living bacteria, which often have specific effects on target organs (Box 6.3).

Intracellular pathogens, including viruses, bacteria (e.g. *Salmonella* spp., *Listeria monocytogenes* and *Mycobacterium tuberculosis*), parasites (e.g. *Leishmania* spp.) and fungi (e.g. *Histoplasma capsulatum*), are able to survive in intracellular environments, including after phagocytosis by macrophages. Pathogenic bacteria express different genes, depending on environmental stress (pH, iron starvation, O<sub>2</sub> starvation etc.) and anatomical location.

Genetic diversity enhances the pathogenic capacity of bacteria. Some virulence factor genes are found on plasmids or in phages and are exchanged between different strains or species. The ability to acquire genes from the gene pool of all strains of the species increases diversity and the potential for pathogenicity. Viruses exploit their rapid reproduction and potential to exchange nucleic acid with other strains of the virus to enhance diversity. Once a new strain acquires sufficient virulence genes, including those enhancing infectivity, it may become an epidemic or pandemic strain, resulting in regional or global transmission, respectively. This phenomenon accounts for influenza and COVID-19 pandemics (see Box 6.10 and Ch. 13).

## The host response

Innate and adaptive immune and inflammatory responses, which humans use to control the normal flora and respond to pathogens, are reviewed in Chapter 4.

6.3 Exotoxin-mediated bacterial diseases	
Disease	Organism
Antibiotic-associated diarrhoea/pseudomembranous colitis	<i>Clostridioides difficile</i>
Botulism	<i>Clostridium botulinum</i>
Cholera	<i>Vibrio cholerae</i>
Diphtheria	<i>Corynebacterium diphtheriae</i>
Haemolytic uraemic syndrome	Enterohaemorrhagic <i>Escherichia coli</i> ( <i>E. coli</i> O157 and other strains)
Necrotising pneumonia	<i>Staphylococcus aureus</i>
Tetanus	<i>Clostridium tetani</i>
Toxic shock syndrome	<i>Staph. aureus</i> <i>Streptococcus pyogenes</i>

## Pathogenesis of infectious disease

The severity of an infection is determined by the virulence of the pathogen and the host response. Whilst an intact host response protects against infection or reduces its severity, an excessive response can be damaging. Both the host immune response and pathogen-produced factors can contribute to tissue injury and systemic manifestations of infection (see 'Sepsis', p. 198). The contribution of the immune response to disease manifestations is exemplified by the immune reconstitution inflammatory syndrome (IRIS), which can be seen in human immunodeficiency virus (HIV) infection, post-transplantation neutropenia or tuberculosis (which causes suppression of T-cell function): there is a paradoxical worsening of the clinical condition as the immune dysfunction is corrected, caused by an exuberant but dysregulated inflammatory response.

### Clinical manifestations of infection

The clinical manifestations of infection can be localised to the site of infection or generalised. Examples of local manifestations include the inflammation of cellulitis, facial pain of sinusitis or neck stiffness of meningitis (Ch. 13). Generalised manifestations include sweats, chills (feeling very cold, even with extra clothes/blankets), rigors, fevers, anorexia, lethargy and generalised aches, and many of these result from the immune response to infection. While the presence of infection may be clinically clear in some settings, often it is not. Identifying the responsible pathogen in patients with infection is usually not possible on clinical grounds, neither is prediction of pathogen susceptibility and resistance to antimicrobial agents. Hence there is a need to carefully investigate suspected infections to optimise, or avoid unnecessary, antimicrobial therapy. Rigors are a clinical symptom (or sign if they are witnessed) characterised by feeling very cold ('chills') and uncontrollable shivering, usually followed by fever and sweating. Rigors occur when the thermoregulatory centre attempts to correct a core temperature to a higher level by stimulating skeletal muscle activity and shaking.

Thermoregulation can be altered during infection, causing both hyperthermia (fever) and hypothermia. Fever is mediated mainly by 'pyrogenic cytokines' (e.g. interleukins IL-1 and IL-6, and tumour necrosis factor (TNF)), which are released in response to various stimuli, including activation of pattern recognition receptors (PRRs) by microbial products (e.g. lipopolysaccharide) and factors released by injured cells (Ch. 4). This induces prostaglandin E<sub>2</sub> production, which binds to specific receptors in the preoptic nucleus of the hypothalamus (thermoregulatory centre), causing the core temperature to rise.

## Investigation of infection

The aims of investigating a patient with suspected infection are: to confirm the presence of infection; identify the specific pathogen(s); and, where appropriate, identify its susceptibility to specific antimicrobial agents in order to optimise therapy. Pathogens may be detected directly (e.g. by culturing a normally sterile body site) or their presence may be inferred by identifying the host response to the organism ('indirect detection', Box 6.4), e.g. C-reactive protein or procalcitonin as part of the acute phase response (p. 68), although these are activated to varying extents by other inflammatory stimuli. Careful sampling increases the likelihood of diagnosis (Box 6.5). Culture results must be interpreted in the context of the normal flora at the sampled site (see Fig. 6.5). The extent to which a microbiological test result supports or excludes a particular diagnosis depends on its statistical performance (e.g. sensitivity, specificity, positive and negative predictive value). Sensitivity and specificity vary according to the type of test, sampling and processing techniques, and time between infection and testing. Positive and negative predictive values depend on the prevalence of the condition in the test population. The complexity of test interpretation is illustrated in Figure 6.8 below, which shows the 'windows of opportunity' afforded by various testing methods. Given this complexity, coordinated thought and action ensures appropriate test application and timing; effective communication between clinicians and the microbiologists facilitates optimal results and interpretation.

## i

## 6.4 Tests used to diagnose infection

**Non-specific markers of inflammation/infection**

- e.g. White cell count in blood sample (WCC), plasma C-reactive protein (CRP), procalcitonin (PCT)\*, serum lactate, cell counts in urine or cerebrospinal fluid (CSF), CSF protein and glucose

**Direct detection of organisms or organism components**

- Microscopy
- Detection of organism components (e.g. antigen, toxin)
- Nucleic acid amplification tests (e.g. polymerase chain reaction)

**Culture of organisms**

- ± Antimicrobial susceptibility testing

**Tests of the host's specific immune response**

- Antibody detection
- Interferon-gamma release assays (IGRA)

\*Although PCT is used increasingly in clinical practice, further evidence is required to establish its precise role in distinguishing bacterial infections from other causes of inflammation.

## 6.5 How to provide samples for microbiological sampling

**Communicate with the laboratory**

- Discuss samples that require processing urgently or that may contain hazardous or unusual pathogens with laboratory staff *before* collection
- Communication is key to optimising microbiological diagnosis. If there is doubt about any aspect of sampling, it is far better to discuss it with laboratory staff beforehand than to risk diagnostic delay by inappropriate sampling or sample handling

**Take samples based on a clinical diagnosis**

- Sampling in the absence of clinical evidence of infection is rarely appropriate (e.g. collecting urine, or sputum for culture)

**Use the correct container**

- Certain tests (e.g. nucleic acid and antigen detection tests) require proprietary sample collection equipment

**Follow sample collection procedures**

- Failure to follow sample collection instructions precisely can result in false-positive (e.g. contamination of blood culture samples) or false-negative (e.g. collection of insufficient blood for culture) results

**Label sample and request form correctly**

- Label sample containers and request forms according to local policies, with demographic identifiers, specimen type and time/date collected
- Include clinical details on request forms
- Identify samples carrying a high risk of infection (e.g. blood liable to contain a blood-borne virus) with a hazard label

**Use appropriate packaging**

- Close sample containers tightly and package securely (usually in sealed plastic bags)
- Attach request forms to samples but not in the same compartment (to avoid contamination, should leakage occur)

**Manage storage and transport**

- Transport samples to the microbiology laboratory quickly
- Consider pre-transport storage, conditions (e.g. refrigeration, incubation, storage at room temperature) vary with sample type
- Notify the receiving laboratory prior to arrival of unusual or urgent samples, to ensure timely processing

**Direct detection of pathogens**

Some direct detection methods provide rapid results and enable detection of organisms that cannot be grown easily on artificial culture media, such as *Chlamydia* spp.; they can also provide information on antimicrobial susceptibility, e.g. *M. tuberculosis*.

**Detection of whole organisms**

Whole organisms are detected by examination of biological fluids or tissue using a microscope.

- *Bright field microscopy* (in which the test sample is interposed between the light source and the objective lens) uses stains to enhance visual contrast between the organism and its background. Examples include Gram staining of bacteria and Ziehl-Neelsen or auramine staining of acid- and alcohol-fast bacilli (AAFB) in tuberculosis (the latter requires an ultraviolet light source). In histopathological examination of tissue samples, stains are used to demonstrate not only the presence of microorganisms but also features of disease pathology.
- *Dark field microscopy* (in which light is scattered to make organisms appear bright on a dark background) is used, for example, to examine genital chancre fluid in suspected syphilis.
- *Electron microscopy* may be used to examine stool and vesicle fluid to detect enteric and herpesviruses, respectively, but its use has largely been supplanted by nucleic acid detection (see below).
- *Flow cytometry* can be used to analyse liquid samples (e.g. urine) for the presence of particles based on properties such as size, impedance and light scatter. This technique can detect bacteria but may misidentify other particles as bacteria too.

**Detection of components of organisms**

Components of microorganisms detected for diagnostic purposes include nucleic acids, cell wall molecules, toxins and other antigens. Commonly used examples include SARS-CoV-2 antigen in respiratory secretions, *Legionella pneumophila* serogroup 1 antigen in urine and cryptococcal polysaccharide antigen in cerebrospinal fluid (CSF). Most antigen detection methods are based on in vitro binding of specific antigen/antibody and are therefore described with serological tests below. Other methods may be used, such as tissue culture cytotoxicity assay for *C. difficile* toxin. In toxin-mediated disease, detection of toxin may be of greater relevance than identification of the organism itself (e.g. stool *C. difficile* toxin).

**Nucleic acid amplification tests**

In a nucleic acid amplification test (NAAT), specific sequences of microbial DNA or RNA are identified using a nucleic acid primer that is amplified exponentially by enzymes to generate multiple copies of a target nucleotide sequence. The most commonly used NAAT is the polymerase chain reaction (PCR; see Fig. 3.11). Reverse transcription PCR (RT-PCR) is used to detect RNA from RNA viruses. The use of fluorescent labels in the reaction enables 'real-time' detection of amplified DNA; quantification is based on the principle that the time taken to reach the detection threshold is proportional to the initial number of copies of the target nucleic acid sequence. In 'broad range' (bacterial) PCR the primers are targeted to parts of the gene that encode 16S ribosomal RNA (rRNA) that have shared DNA sequences across most bacteria. Between these shared DNA sequences, the 16S rRNA gene varies between species; so, using PCR, nucleotide sequencing of the product and comparison of the DNA sequence information with large databases, bacterial detection and species identification can be achieved. In multiplex PCR, multiple primer pairs are used to enable detection of several different organisms in a single reaction.

Determination of nucleotide sequences in a target gene(s) can be used to assign microorganisms to specific strains, which may be relevant to treatment and/or prognosis (e.g. in hepatitis C infection). Genes that are relevant to virulence (such as toxin genes) or antimicrobial resistance can also be detected; for example, the *mecA* gene can be used to screen for MRSA.

NAATs are the most sensitive direct detection methods and are also relatively rapid. They are used widely in virology, where the possibility of false-positive results from colonising or contaminating organisms is

remote, and are applied to blood, respiratory samples, stool and urine. In bacteriology, PCR is used to examine CSF, blood, tissue and genital samples, and multiplex PCR is being developed for use in faeces. PCR is particularly helpful for microorganisms that cannot be readily cultured, e.g. *Tropheryma whippelii*, and is being used increasingly in mycology and parasitology.

## Culture

Microorganisms may be both detected and further characterised by culture from clinical samples (e.g. tissue, swabs and body fluids).

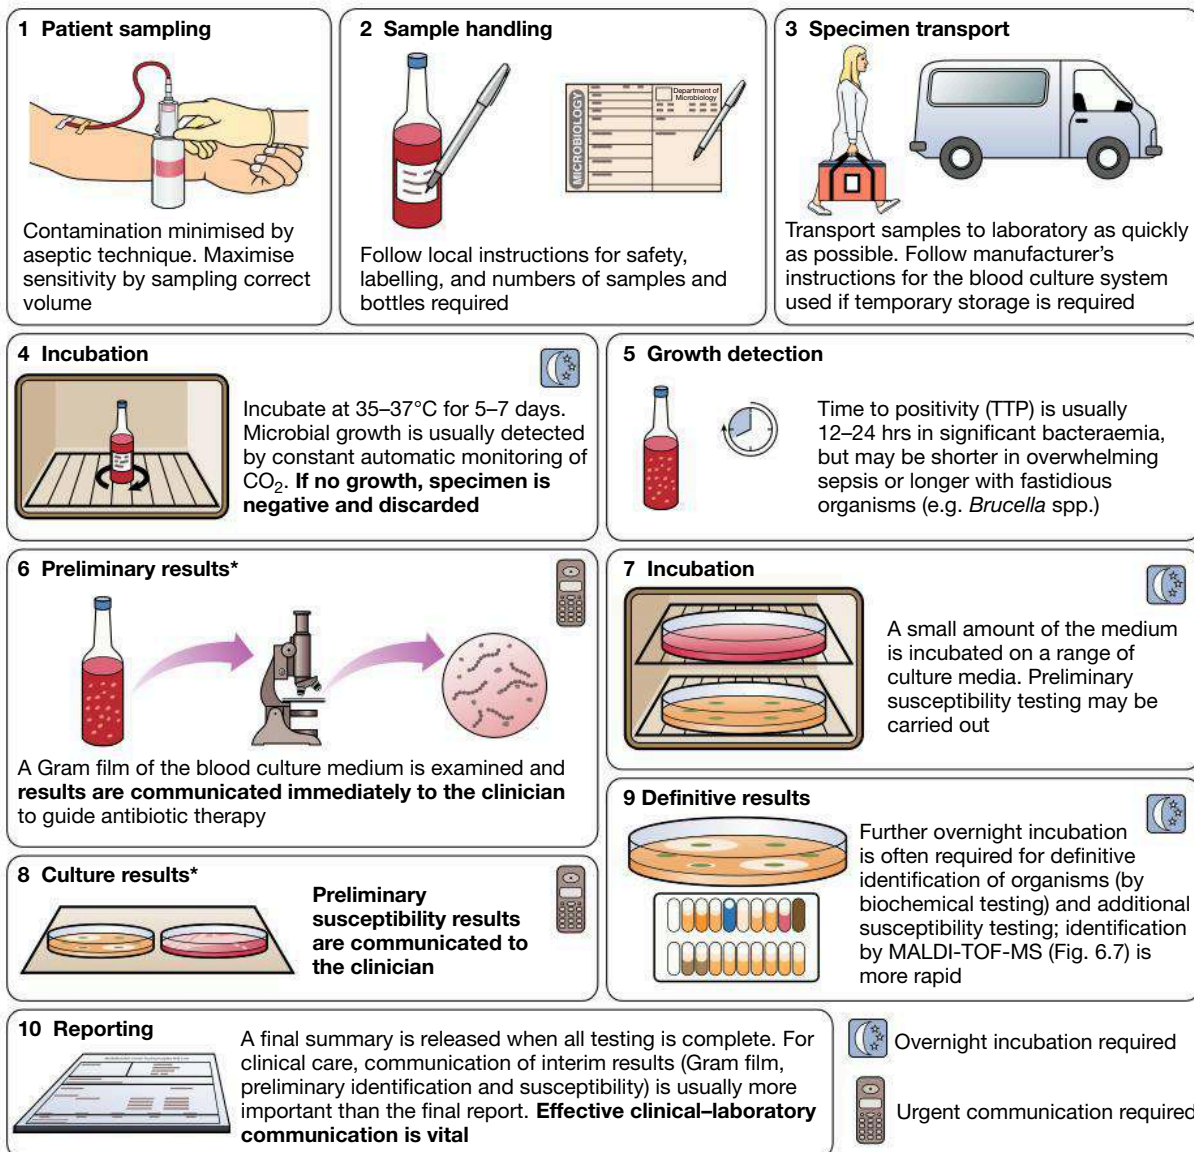

- *Ex vivo culture* (tissue or cell culture) was widely used in the isolation of viruses but has been largely supplanted by NAATs.
- *In vitro culture* (in artificial culture media) of bacteria and fungi is used to confirm the presence of pathogens, allow identification, test antimicrobial susceptibility and subtype the organism for epidemiological purposes.

Culture has its limitations: results are not immediate, even for organisms that are easy to grow, and negative cultures rarely exclude infection. Organisms such as *M. tuberculosis* are slow-growing, typically taking at

least 2 weeks, even in rapid-culture systems. Certain organisms, such as *Mycobacterium leprae* and *Tropheryma whippelii*, cannot be cultivated on artificial media, and others (e.g. *Chlamydia* spp. and viruses) grow only in culture systems, which are slow and labour-intensive.

## Blood culture

The terms 'bacteraemia' and 'fungaemia' describe the presence of bacteria and fungi in the blood without implication of clinical significance, while the term 'blood stream infection' means bacteraemia or fungaemia are present together with symptoms or signs infection; this is discussed on p. 270. Bacteraemia/fungaemia is identified by inoculating a liquid culture medium with freshly drawn blood, which is then incubated in a system that monitors it constantly for growth of microorganisms (e.g. by detecting products of microbial respiration using fluorescence; Fig. 6.6). If growth is detected, organisms are identified and sensitivity testing is performed. Traditionally, identification has been achieved by Gram stain appearance and biochemical reactions. However, matrix-assisted laser desorption/ionisation time-of-flight mass spectroscopy (MALDI-TOF-MS; see Box 6.2) is being used increasingly to identify organisms. MALDI-TOF-MS produces a profile of proteins of different sizes from the target microorganism and uses databases of such

**Fig. 6.6** An overview of the processing of blood cultures. \*In laboratories equipped with MALDI-TOF-MS (see Fig. 6.7), rapid definitive organism identification may be achieved at stage 6 and/or stage 8.

**Fig. 6.7** The workings of matrix-assisted laser desorption/ionisation time-of-flight mass spectrometry (MALDI-TOF MS). Adapted from Sobin K, Hameer D, Ruparel T. *Digital genotyping using molecular affinity and mass spectrometry*. *Nature Rev Genet* 2003; 4:1001–1008.

profiles to identify the organism (Fig. 6.7). It is rapid and accurate. Taking multiple blood samples for culture at different times allows differentiation of transient (one positive sample) and persistent (majority are positive) bacteraemia. This can be clinically important in identifying the source of infection.

## Indirect detection of pathogens

Tests may be used to detect the host's immune (antibody) response to a specific microorganism, and can enable the diagnosis of infection with organisms that are difficult to detect by other methods or are no longer present in the host. The term 'serology' describes tests carried out on serum and includes both antigen (direct) and antibody (indirect) detection. Antigen detection tests used on other fluids (e.g. CSF and respiratory secretions) are also described in this section, as they largely share the same methodology as serological tests.

### Antibody detection

Organism-specific antibody detection is applied mainly to blood (Fig. 6.8). Results are typically expressed as titres: that is, the reciprocal of the highest dilution of the serum at which antibody is detectable (e.g. detection at serum dilution of 1:64 gives a titre of 64). 'Seroconversion' is defined as either a change from negative to positive detection or a fourfold rise in titre between acute and convalescent serum samples. An acute sample is usually taken during the first week of disease and the convalescent sample 2–4 weeks later. Earlier diagnosis can be achieved by detection of immunoglobulin M (IgM) antibodies, which are produced early in infection. A limitation of these tests is that antibody production requires a fully functional host immune system, so there may be false-negative results in immunocompromised patients. Also, other than in chronic infections and with IgM detection, antibody tests usually provide a retrospective diagnosis. False-positive results can occur when there is cross-reactivity of the test reagents with other molecules or when patients have been given blood products containing other people's antibodies. Serological testing methods are described below.

**Fig. 6.8** Detection of antigen, nucleic acid and antibody in infectious disease. The acute sample is usually taken during the first week of illness, and the convalescent sample 2–4 weeks later. Detection limits and duration of detectability vary between tests and diseases, although in most diseases immunoglobulin M (IgM) is detectable within the first 1–2 weeks.

### Enzyme-linked immunosorbent assay

The principles of the enzyme-linked immunosorbent assay (ELISA, EIA) are illustrated in Figure 6.9. These assays rely on linking an antibody with an enzyme that generates a colour change on exposure to a chromogenic substrate. Various configurations allow detection of antigens or specific subclasses of immunoglobulin (e.g. IgG, IgM, IgA). ELISA may also be adapted to detect PCR products, using immobilised oligonucleotide hybridisation probes and various detection systems.

### Immunoblot (Western blot)

Microbial proteins are separated according to molecular weight by polyacrylamide gel electrophoresis (PAGE) and transferred (blotted) on to a nitrocellulose membrane, which is incubated with patient serum. Binding of specific antibody is detected with an enzyme–anti-immunoglobulin conjugate similar to that used in ELISA, and specificity is confirmed by its location on the membrane. Immunoblotting is a highly specific test, which may be used to confirm the results of less specific tests such as ELISA (e.g. in Lyme disease).

### Immunofluorescence assays

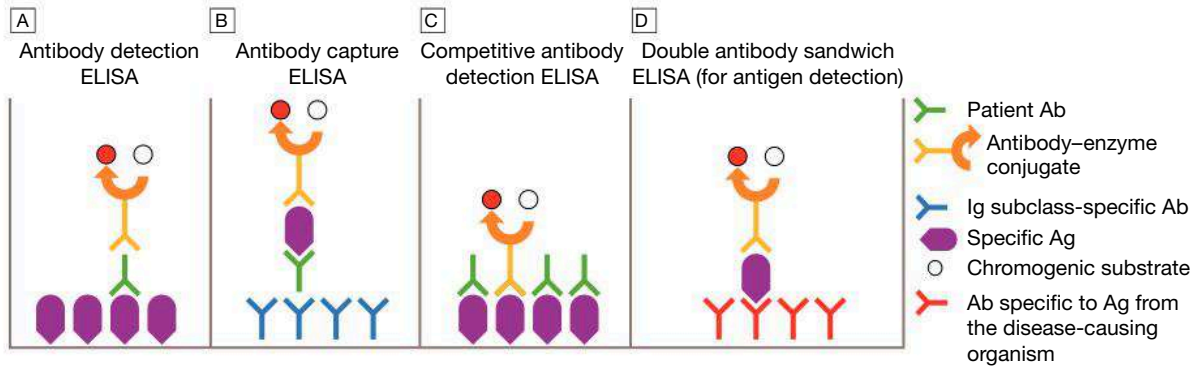

Indirect immunofluorescence assays (IFAs) detect antibodies by incubating a serum sample with immobilised antigen (e.g. virus-infected cells on a glass slide); any virus-specific antibody present in the serum binds to antigen and is then detected by fluorescence microscopy using a fluorescent-labelled anti-human immunoglobulin ('secondary' antibody). This method can also detect organisms in clinical samples (usually tissue or centrifuged cells) using a specific antibody in place of immobilised antigen to achieve capture.

### Complement fixation test (CFT)

In a CFT, patient serum is heat-treated to inactivate complement and mixed with test antigen. Any specific antibody in the serum will complex with the antigen. Complement is then added to the reaction. If antigen–antibody complexes are present, the complement will be 'fixed' (consumed). Sheep erythrocytes, coated with an anti-erythrocyte antibody, are added. The degree of erythrocyte lysis reflects the remaining complement and is inversely proportional to the quantity of the specific antigen–antibody complex present.

### Agglutination tests

When antigens are present on the surface of particles (e.g. cells, latex particles or microorganisms) and cross-linked with antibodies, visible clumping (or 'agglutination') occurs.

**Fig. 6.9** Antibody (Ab) and antigen (Ag) detection by enzyme-linked immunosorbent assay (ELISA). This can be configured in various ways. **A** Patient Ab binds to immobilised specific Ag and is detected by addition of anti-immunoglobulin–enzyme conjugate and chromogenic substrate. **B** Patient Ab binds to immobilised Ig subclass-specific Ab and is detected by addition of specific Ag, followed by antibody–enzyme conjugate and chromogenic substrate. **C** Patient Ab and antibody–enzyme conjugate bind to immobilised specific Ag. Magnitude of colour change reaction is inversely proportional to concentration of patient Ab. **D** Patient Ag binds to immobilised Ab and is detected by addition of antibody–enzyme conjugate and chromogenic substrate. In A, the conjugate Ab is specific for human immunoglobulin. In B–D, it is specific for Ag from the disease-causing organism.

- In *direct agglutination*, patient serum is added to a suspension of organisms that express the test antigen. The Widal agglutination test uses a suspension of *Salmonella typhi* and *S. paratyphi* ‘A’ and ‘B’, treated to retain only ‘O’ and ‘H’ antigens. These antigens are kept to detect corresponding antibodies in serum from a patient suspected of having typhoid fever.
- In *indirect (passive) agglutination*, specific antigen is attached to the surface of carrier particles, which agglutinate when incubated with patient samples that contain specific antibodies.
- In *reverse passive agglutination* (an antigen detection test), the carrier particle is coated with antibody rather than antigen.

### Immunodiffusion

Immunodiffusion involves antibodies and antigen migrating through gels and forming insoluble complexes where they meet. The complexes are seen on staining as ‘precipitin bands’. Immunodiffusion is used in the diagnosis of dimorphic fungi and some forms of aspergillosis.

### Lateral flow immunochromatography

Lateral flow (LF) immunochromatography is mainly used to detect antigens, and often in fluids other than blood (e.g. respiratory secretions, urine). The system consists of a porous test strip (e.g. a nitrocellulose membrane), at one end of which there is target-specific antibody, complexed with coloured microparticles. Further specific antibody is immobilised in a transverse narrow line some distance along the strip. Test material is added to the antibody–particle complexes, which then migrate along the strip by capillary action. If these are complexed with antigen, they will be immobilised by the specific antibody and visualised as a transverse line across the strip. If the test is negative, the antibody–particle complexes will bind to a line of immobilised anti-immunoglobulin antibody placed further along the strip, which acts as a negative control. Immunochromatographic tests are rapid and relatively cheap to perform, and are appropriate for point-of-care testing, e.g. in HIV-1, COVID-19 and malaria.

### Antibody-independent specific immunological tests

Interferon-gamma release assays (IGRA) are used to diagnose latent tuberculosis infection. The principle behind IGRA is illustrated in Fig. 17.42. IGRA cannot distinguish between latent and active tuberculosis infection and is therefore appropriate for use only in regions where the background incidence of tuberculosis is low.

### Antimicrobial susceptibility testing

If growth of microorganisms in culture is inhibited by the addition of an antimicrobial agent, the organism is considered to be susceptible to that antimicrobial. Bacteriostatic agents cause reversible inhibition of

replication and bactericidal agents cause cell death; the terms fungistatic/fungicidal are equivalent for antifungal agents, and virustatic/virucidal for antiviral agents. The lowest concentration of the antimicrobial agent at which growth is inhibited is the minimum inhibitory concentration (MIC), and the lowest concentration that causes cell death is the minimum bactericidal concentration (MBC). If the MIC is less than or equal to a predetermined breakpoint threshold, the organism is considered susceptible, and if the MIC is greater than the breakpoint, it is resistant. Breakpoints are determined for antimicrobial agents using a combination of pharmacokinetic and clinical data. The relationship between in vitro antimicrobial susceptibility and clinical response is complex, as response also depends on severity of illness, site of infection, pharmacokinetics, immune status, comorbidities and antibiotic dosing. Thus, although treating a patient according to the results of susceptibility testing increases the likelihood of recovery, it does not guarantee therapeutic success.

Susceptibility testing is often carried out by disc diffusion (Fig. 6.10). Antibiotic-impregnated filter paper discs are placed on agar plates containing bacteria; antibiotic diffuses into the agar, resulting in a concentration gradient centred on the disc. Bacteria are unable to grow where the antibiotic concentration exceeds the MIC, which may therefore be inferred from the size of the zone of inhibition. The MIC is commonly measured in diagnostic laboratories using ‘diffusion strips’.

## Epidemiology of infection

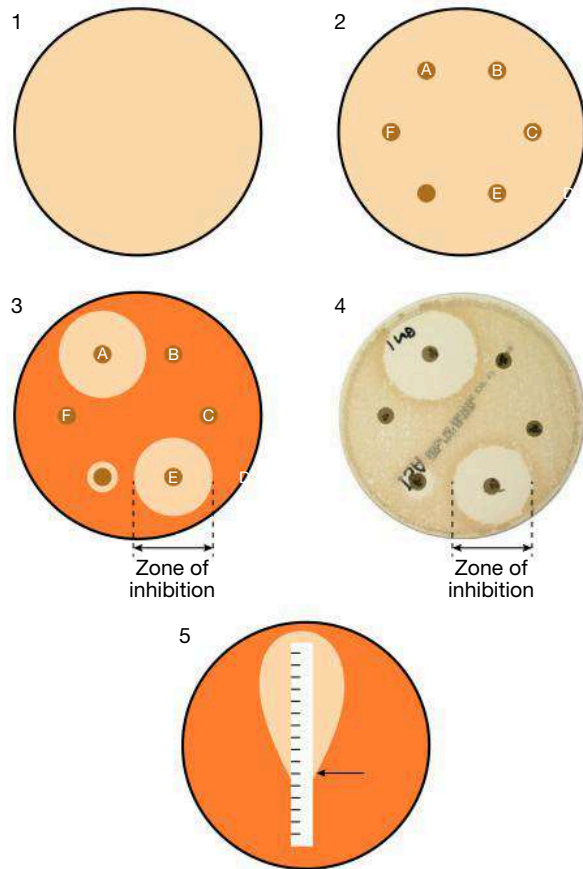

The communicability of many infections means that, once a clinician has diagnosed an infectious disease, potential exposure of other patients must also be considered. Measures to control spread may be required at a patient level (e.g. separation from other patients (‘isolation’)), at an organisation or institutional levels (e.g. in a nursing home (Ch. 5) or hospital) at a national level, or, in the case of a pandemic, at an international level. The approach will be specific to the microorganism involved (Chs. 11–13) but the principles are outlined below.

### Geographical and temporal patterns of infection

#### Endemic disease

Endemic disease has a constant presence within a given geographical area or population. The infectious agent may have a reservoir, vector or intermediate host that is geographically restricted, or may itself have restrictive environmental requirements (e.g. temperature range, humidity). The population affected may be geographically isolated or the disease may be limited to unvaccinated populations. Factors that alter geographical restriction include:

- expansion of an animal reservoir (e.g. Lyme disease from reforestation)
- vector escape (e.g. airport malaria)

**Fig. 6.10** Antimicrobial susceptibility testing by disc diffusion (panels 1–4) and minimum inhibitory concentration (MIC, panel 5). 1 The test organism is spread over the surface of an agar plate. 2 Antimicrobial-impregnated discs (A–F) are placed on the surface and the plate is incubated (e.g. overnight). 3–4 After incubation, zones of growth inhibition may be seen. The organism is considered susceptible if the diameter of the zone of inhibition exceeds a predetermined threshold. 5 In a ‘diffusion strip’ test, the strip is impregnated with antimicrobial at a concentration gradient that decreases steadily from top to bottom. The system is designed so that the MIC value is the point at which the ellipse cuts a scale on the strip (arrow). (4) Kindly supplied by Charlotte Symes.

- extension of host range (e.g. schistosomiasis from dam construction)
- importation of foods
- human migration (e.g. carbapenemase-producing *Klebsiella pneumoniae*)
- public health service breakdown (e.g. diphtheria in unvaccinated areas)
- climate change (e.g. dengue virus and Rift Valley fever).

### Emerging and re-emerging disease

An emerging infectious disease is one that has newly appeared in a population, or has been known for some time but is increasing in incidence or geographical range. If the disease was previously known and thought to have been controlled or eradicated, it is considered to be re-emerging. Many emerging diseases are caused by organisms that infect animals and have undergone adaptations that enable them to infect humans. This is exemplified by HIV-1, which originated in higher primates in Africa, and SARS-CoV-2, from bats potentially via intermediate hosts. The geographical pattern of some recent emerging and re-emerging infections is shown in Figure 6.11.

### Reservoirs of infection

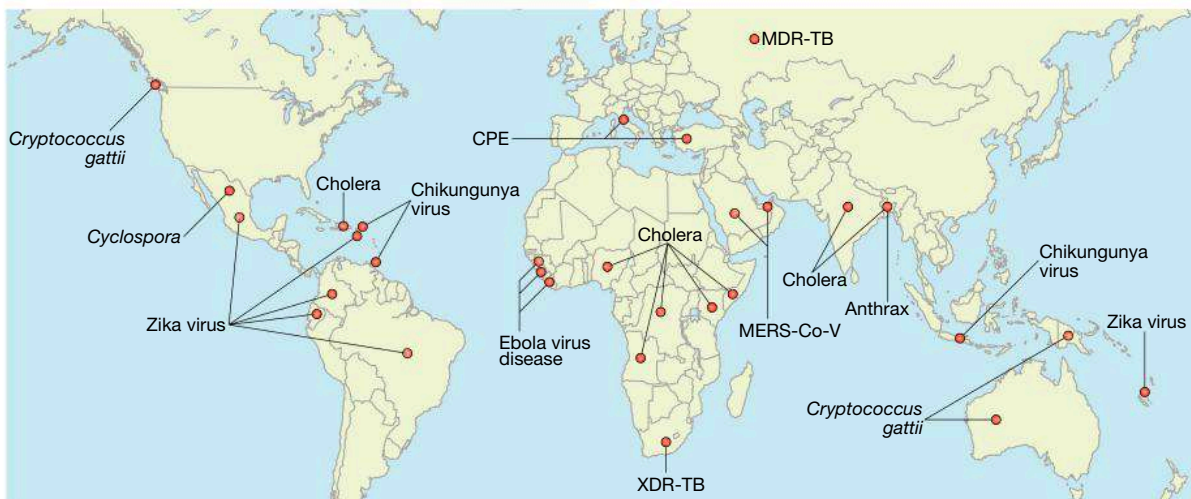

The US Centers for Disease Control (CDC) define a reservoir of infection as any person, other living organism, environment or combination of these in which the infectious agent lives and replicates and on which the infectious agent is dependent for its survival. The infectious agent is transmitted from this reservoir to a susceptible host.

#### Human reservoirs

Both colonised and infected individuals can act as human reservoirs, and infected human reservoirs may be asymptomatic. The organism must be long-lasting in at least a proportion of those affected, to facilitate onward transmission. Infections in which humans act as reservoirs include tuberculosis, MRSA, HIV and COVID-19. For some infections (e.g. measles) humans are the only known reservoir.

#### Animal reservoirs

The World Health Organization (WHO) defines a zoonosis as ‘a disease or infection that is naturally transmissible from vertebrate animals to

**Fig. 6.11** Geographical locations of some infectious disease outbreaks, with examples of emerging and re-emerging diseases. (CPE = carbapenemase-producing *Enterobacteriales*; MDR-TB = multidrug-resistant tuberculosis; MERS-Co-V = Middle East respiratory syndrome coronavirus; XDR-TB = extensively drug-resistant tuberculosis)

humans'. Infected animals may be asymptomatic. Zoonotic agents may be transmitted via any of the routes described below. Primary infection with zoonoses may be transmitted onward between humans, causing secondary disease (e.g. Q fever, brucellosis, Ebola virus disease).

### Environmental reservoirs

Some pathogens are acquired from an environmental source (e.g. *Pseudomonas aeruginosa* from hospital water supplies). However, some of these are maintained in human or animal reservoirs, with the environment acting only as a conduit for infection.

## Transmission of infection

Communicable diseases may be transmitted by one or more of the following routes:

- Respiratory route: airborne/droplet spread (see p. 293).
- Faecal–oral route: ingestion of material originating from faeces.
- Sexually transmitted infections: direct contact between mucous membranes.
- Blood-borne infections: direct inoculation of blood.
- Direct contact: very few organisms are capable of causing infection by direct contact with intact skin. Most infection by this route requires contact with damaged skin (e.g. surgical wound).
- Via a vector or fomite: the vector/fomite bridges the gap between the infected host or reservoir and the uninfected host. Vectors are animate, and include mosquitoes in malaria and dengue virus infection and humans in MRSA. Fomites are inanimate objects such as door handles, water taps and ultrasound probes, which are particularly associated with health care-associated infection (HCAI).

The basic reproduction number ( $R_0$ ) is a measure of the propensity for a communicable disease to spread between people; it is the average number of people one person with an infection is likely to pass on infection to.  $R_0$  is calculated by mathematical models that take into account infection rates, the period of infectivity (known or estimated), opportunities for transmission and susceptibility to infection.  $R_0$  assumes everyone is susceptible, whereas 'effective  $R$ ' ( $R_e$ ) takes into account the development of herd immunity within the population (e.g. from infection or vaccination) and therefore varies with time.  $R_0$  and  $R_e$  are calculated for whole populations, so will hide local variations in transmission.

The likelihood of infection following transmission of a pathogen depends on the virulence of the organism and the susceptibility of the host. The incubation period is the time between exposure and development of symptoms, and the period of infectivity is the period after exposure during which the patient is infectious to others. Knowledge of incubation periods and periods of infectivity is important in controlling the spread of disease, although for many diseases these estimates are imprecise (Boxes 6.6 and 6.7).

### Deliberate release

Deliberate release of pathogens with the intention of causing disease is known as biological warfare or bioterrorism. Deliberate release incidents have included a 750-person outbreak of *Salmonella typhimurium* caused by contamination of salads in 1984 (Oregon, USA) and 22 cases of anthrax (five fatal) from the mailing of finely powdered (weaponised) anthrax spores in 2001 (New Jersey, USA). Diseases with high potential for deliberate release include anthrax, plague, tularaemia, smallpox and botulism (through toxin release).

## Infection prevention and control

Infection prevention and control (IPC) describes the measures applied to populations with the aim of breaking the chain of infection (see Fig. 6.1).

### 6.6 Incubation periods of important infections<sup>1</sup>

Infection	Incubation period
<b>Short incubation periods</b>	
Anthrax, cutaneous <sup>2</sup>	9 hrs to 2 weeks
Anthrax, inhalational <sup>2</sup>	2 days <sup>3</sup>
Bacillary dysentery <sup>4</sup>	1–6 days
Cholera <sup>2</sup>	2 hrs to 5 days
Dengue haemorrhagic fever <sup>5</sup>	3–14 days
Diphtheria <sup>5</sup>	1–10 days
Gonorrhoea <sup>6</sup>	2–10 days
Influenza <sup>4</sup>	1–3 days
Meningococcaemia <sup>2</sup>	2–10 days
Norovirus	1–3 days
SARS <sup>2</sup>	2–7 days <sup>3</sup>
Scarlet fever <sup>4</sup>	2–4 days
<b>Intermediate incubation periods</b>	
Amoebiasis <sup>5</sup>	1–4 weeks
Brucellosis <sup>5</sup>	5–30 days
Chickenpox <sup>4</sup>	11–20 days
COVID-19 (SARS-CoV-2)	5–6 days <sup>2</sup>
Lassa fever <sup>2</sup>	3–21 days
Malaria <sup>2</sup>	10–15 days
Measles <sup>4</sup>	6–19 days
Mumps <sup>4</sup>	15–24 days
Poliomyelitis <sup>5</sup>	3–35 days
Psittacosis <sup>5</sup>	1–4 weeks
Rubella <sup>4</sup>	15–20 days
Typhoid <sup>4</sup>	5–31 days
Whooping cough <sup>4</sup>	5–21 days
<b>Long incubation periods</b>	
Hepatitis A <sup>4</sup>	3–7 weeks
Hepatitis B <sup>6</sup>	6 weeks to 6 months
Leishmaniasis, cutaneous <sup>5</sup>	Weeks to months
Leishmaniasis, visceral <sup>5</sup>	Months to years
Leprosy (Hansen's disease) <sup>2</sup>	5–20 years
Rabies <sup>5</sup>	3–12 weeks <sup>3</sup>
<i>Trypanosoma brucei gambiense</i> infection <sup>5</sup>	Months to years
Tuberculosis <sup>4</sup>	1–12 months

<sup>1</sup>Incubation periods are approximate and may differ from local or national guidance. <sup>2</sup>World Health Organization. <sup>3</sup>Longer incubation periods have been reported. <sup>4</sup>Richardson M, et al. Paediatr Infect Dis J 2001; 20:380–88. <sup>5</sup>Centers for Disease Control, USA. <sup>6</sup>Public Health England. (SARS = severe acute respiratory syndrome)

### 6.7 Periods of infectivity in common childhood infectious diseases

Disease	Infectious period
Chickenpox <sup>1</sup>	From 4 days before until 5 days after appearance of the rash (transmission before 48 hrs prior to the onset of rash is rare) <sup>4</sup>
Measles <sup>2</sup>	From 4 days before onset to 4 days after onset of the rash
Mumps <sup>3</sup>	From 2–3 days before to 5 days after disease onset <sup>5</sup>
Rubella <sup>3</sup>	From 10 days before until 15 days after the onset of the rash, but most infectious during prodromal illness <sup>4</sup>
Scarlet fever <sup>1</sup>	Unknown <sup>6</sup>
Whooping cough <sup>1</sup>	Unknown <sup>6,7</sup>

<sup>1</sup>From Richardson M, Elliman D, Maguire H, et al. Paediatr Infect Dis J 2001; 20:380–388. <sup>2</sup>Centers for Disease Control, USA; cdc.gov/measles/hcp/. <sup>3</sup>Bennett JE, Dolin R, Blaser MJ. Mandell, Douglas and Bennett's Principles and practice of infectious diseases, 8th edn. Philadelphia: Elsevier; 2015. <sup>4–6</sup>Exclude from contact with non-immune and immunocompromised people for 5 days from <sup>4</sup>onset of rash <sup>5</sup>onset of parotitis, or <sup>6</sup>start of antibiotic treatment. <sup>7</sup>Exclude for 3 weeks if untreated. Durations are approximate and vary between information sources, and these recommendations may differ from local or national guidance.

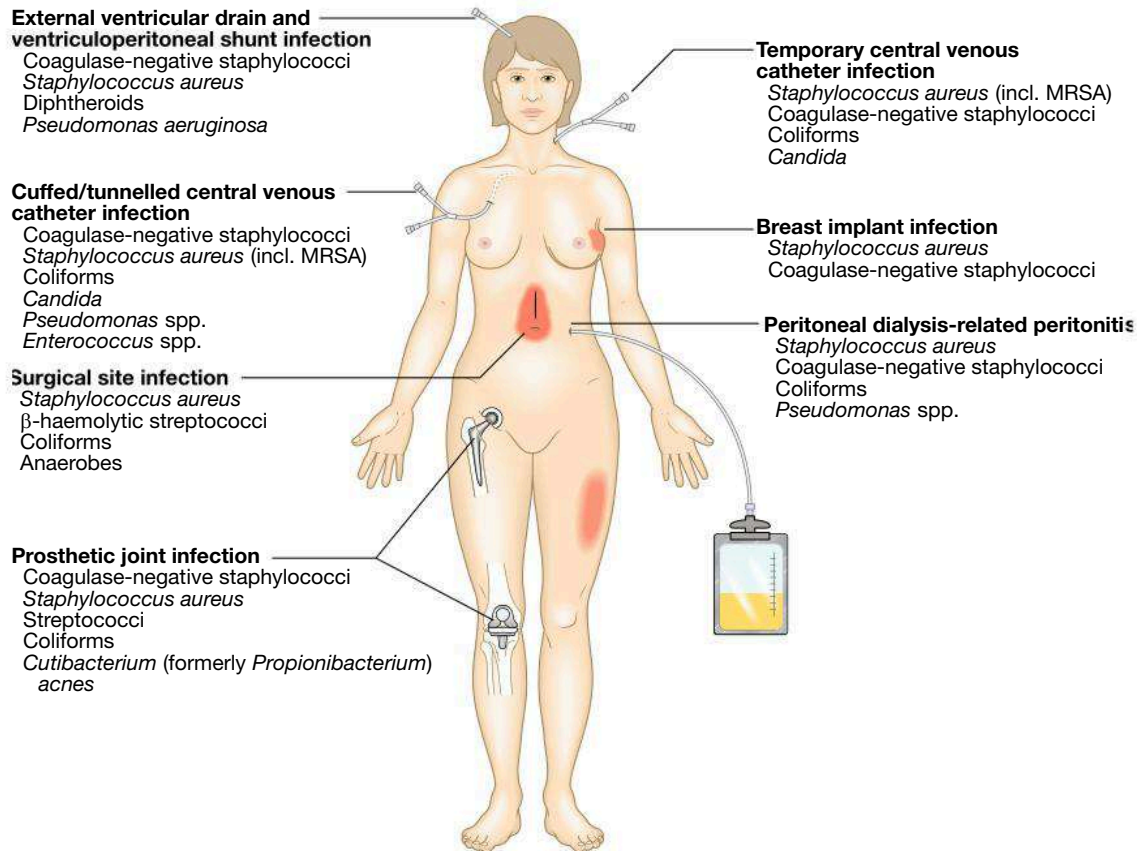

Fig. 6.12 Commonly encountered health care-associated infections (HCAIs) and the factors that predispose to them.

## Health care-associated infection

The risk of developing infection following admission to a health-care facility (health care-associated infection, HCAI) in the developed world is about 10%. Many nosocomial bacterial infections are caused by organisms that are resistant to numerous antibiotics (multi-resistant bacteria), including MRSA, extended-spectrum  $\beta$ -lactamases (ESBLs) and carbapenemase-producing *Enterobacteriales* (CPE), and glycopeptide-resistant enterococci (GRE). Other infections of particular concern in hospitals include *C. difficile* and norovirus. Some examples are shown in Figure 6.12.

IPC measures are described in Box 6.8. The most important is maintenance of good hand hygiene (Fig. 6.13). Hand decontamination (e.g. using alcohol gel or washing) is mandatory before and after every patient contact. Decontamination with alcohol gel is usually adequate but hand-washing (with hot water, liquid soap and complete drying) is required after any procedure that involves more than casual physical contact, or if hands are visibly soiled. In situations where the prevalence of *C. difficile* is high (e.g. a local outbreak), alcohol gel decontamination between patient contacts is inadequate as it does not kill *C. difficile* spores, and hands must be washed.

Some infections necessitate additional measures to prevent cross-infection (Box 6.9) and sometimes these are combined, e.g. both droplet and contact precautions in the case of SARS-CoV-2. To minimise risk of infection, invasive procedures must be performed using strict aseptic technique.

## Outbreaks of infection

Descriptive terms for infectious disease outbreaks are defined in Box 6.10. Confirmation of an infectious disease outbreak usually requires evidence from 'typing' that the causal organisms have identical

i	6.8 Measures used in infection prevention and control (IPC)
	<b>Organisational measures</b> <ul style="list-style-type: none"> <li>• Handling, storage and disposal of clinical waste</li> <li>• Containment and safe removal of spilled blood and body fluids</li> <li>• Cleanliness of environment and medical equipment</li> <li>• Specialised ventilation (e.g. laminar flow, air filtration, controlled pressure gradients)</li> <li>• Sterilisation and disinfection of instruments and equipment</li> <li>• Food hygiene</li> <li>• Laundry management</li> </ul>
	<b>Health-care staff interventions</b> <ul style="list-style-type: none"> <li>• Education</li> <li>• Hand hygiene, including hand-washing (see Fig. 6.13)</li> <li>• Sharps management and disposal</li> <li>• Use of personal protective equipment (PPE, e.g. masks, sterile and non-sterile gloves, gowns and aprons)</li> <li>• Screening health workers for disease (e.g. tuberculosis, hepatitis B virus, MRSA)</li> <li>• Immunisation and post-exposure prophylaxis</li> </ul>
	<b>Clinical practice</b> <ul style="list-style-type: none"> <li>• Antibiotic stewardship</li> <li>• Aseptic technique</li> <li>• Perioperative antimicrobial prophylaxis</li> <li>• Screening patients for colonisation or infection (e.g. MRSA, GRE, CPE)</li> </ul>
	<b>Response to infections</b> <ul style="list-style-type: none"> <li>• Surveillance to detect alert organism (see text) outbreaks and antimicrobial resistance</li> <li>• Antibiotic chemoprophylaxis in infectious disease contacts, if indicated (see Box 6.19)</li> <li>• Isolation (see Box 6.9)</li> <li>• Reservoir control</li> <li>• Vector control</li> </ul>
	<b>Population measures</b> <ul style="list-style-type: none"> <li>• See Box 6.12 and p. 293</li> </ul>
	<small>(CPE = carbapenemase-producing <i>Enterobacteriales</i>; GRE = glycopeptide-resistant enterococci; MRSA = methicillin-resistant <i>Staphylococcus aureus</i>)</small>

**Fig. 6.13 Hand-washing.** Good hand hygiene, whether with soap/water or alcohol handrub, includes areas that are often missed, such as fingertips, web spaces, palmar creases and the backs of hands. 6.9 Types of isolation precaution <sup>1</sup>		
Airborne transmission	Contact transmission	Droplet transmission
<b>Precautions</b>		
Negative pressure room with air exhausted externally or filtered N95 masks or personal respirators for staff Avoid using non-immune staff	Private room preferred (otherwise, inter-patient spacing $\geq 1$ m) Gloves and gown for staff in contact with patient or contaminated areas	Private room preferred (otherwise, inter-patient spacing $\geq 1$ m) Surgical masks for staff in close contact with patient
<b>Examples of infections managed with these precautions</b>		
Measles Tuberculosis, pulmonary or laryngeal, suspected	Enteroviral infections in young children (diapered or incontinent) Norovirus <i>Clostridioides difficile</i> infection Multidrug-resistant organisms (e.g. MRSA, ESBL, GRE, VRSA, penicillin-resistant <i>Streptococcus pneumoniae</i> ) <sup>2</sup> Parainfluenza in infants and young children Rotavirus RSV in infants, children and immunocompromised Viral conjunctivitis, acute	Diphtheria, pharyngeal <i>Haemophilus influenzae</i> type b infection Herpes simplex infection, disseminated or severe Influenza Meningococcal infection Mumps <i>Mycoplasma pneumoniae</i> Parvovirus (erythrovirus) B19 (erythema infectiosum, fifth disease) Pertussis Plague, pneumonic Rubella <i>Streptococcus pyogenes</i> (group A), pharyngeal
<b>Infections managed with multiple precautions</b>		
← Smallpox, monkeypox, VZV (chickenpox or disseminated disease) <sup>3</sup> →		
← SARS-CoV-2, <sup>4</sup> adenovirus pneumonia →		
← SARS, viral haemorrhagic fever →		
<p><sup>1</sup>Recommendations based on 2007 CDC guideline for isolation precautions, revised in July 2019. May differ from local or national recommendations. <sup>2</sup>Subject to local risk assessment. <sup>3</sup>Or in any immunocompromised patient until possibility of disseminated infection excluded. <sup>4</sup>SARS-CoV-2 and other respiratory viruses are managed with airborne precautions in certain circumstances (see p. 293). (ESBL = extended-spectrum <math>\beta</math>-lactamase; GRE = glycopeptide-resistant enterococci; MRSA = methicillin-resistant <i>Staphylococcus aureus</i>; RSV = respiratory syncytial virus; SARS = severe acute respiratory syndrome; VRSA = vancomycin-resistant <i>Staphylococcus aureus</i>; VZV = varicella zoster virus)</p>		

phenotypic and/or genotypic characteristics. When an outbreak of infection is suspected, a case definition is agreed. The number of cases that meet the case definition is then assessed by case-finding, using methods ranging from administration of questionnaires to national reporting systems. Case-finding usually includes microbiological testing, at least in the early stages of an outbreak. Temporal changes in cases are noted in order to plot an outbreak curve, and demographic details are collected to identify possible sources of infection. A case-control study, in which recent activities (potential exposures) of affected

‘cases’ are compared to those of unaffected ‘controls’, may be undertaken to establish the outbreak source, and measures are taken to manage the outbreak and control its spread. Good communication between relevant personnel during and after the outbreak is important to inform practice in future outbreaks.

Surveillance ensures that disease outbreaks are either prevented or identified early. In hospitals, staff are made aware of the isolation of ‘alert organisms’, which have the propensity to cause outbreaks, and ‘alert conditions’, which are likely to be caused by such organisms. Analogous

## 6.10 Terminology in outbreaks of infection

Term	Definition
<b>Classification of related cases of infectious disease*</b>	
Cluster	An aggregation of cases of a disease that are closely grouped in time and place, and may or may not exceed the expected number
Epidemic	The occurrence of more cases of disease than expected in a given area or among a specific group of people over a particular period of time
Outbreak	Synonymous with epidemic. Alternatively, a localised, as opposed to generalised, epidemic
Pandemic	An epidemic occurring over a very wide area (several countries or continents) and usually affecting a large proportion of the population
<b>Classification of affected patients (cases)</b>	
Index case	The first case identified in an outbreak
Primary cases	Cases acquired from a specific source of infection
Secondary cases	Cases acquired from primary cases
<b>Types of outbreak</b>	
Common source outbreak	Exposure to a common source of infection (e.g. water-cooling tower, medical staff member shedding MRSA). New primary cases will arise until the source is no longer present
Point source outbreak	Exposure to a single source of infection at a specific point in time (e.g. contaminated food at a party). Primary cases will develop disease synchronously
Person-to-person spread	Outbreak with both primary and secondary cases. May complicate point source or common source outbreak

\*Adapted from cdc.gov. (MRSA = methicillin-resistant *Staphylococcus aureus*)

systems are used nationally; many countries publish lists of organisms and diseases, which, if detected (or suspected), must be reported to public health authorities. Reasons why a disease might be reportable are shown in [Box 6.11](#).

A pandemic is the most extensive form of outbreak, in which the disease spreads over a wide area and may affect a large proportion of the population. The most recent pandemic was the COVID-19 pandemic of 2019 onwards. The measures that may be put in place in an attempt to control a pandemic are shown in [Box 6.12](#).

## Immunisation

Immunisation may be passive or active. Passive immunisation is achieved by administering antibodies targeting a specific pathogen. Antibodies are obtained from blood, so confer some of the infection risks associated with blood products. The protection afforded by passive immunisation is immediate but of short duration (a few weeks or months); it is used to prevent or attenuate infection before or after exposure ([Box 6.13](#)).

## Vaccination

Active immunisation is achieved by vaccination with whole organisms, organism components or nucleic acids (DNA/RNA) ([Box 6.14](#)).

### Types of vaccine

Whole-cell vaccines consist of live or inactivated (killed) microorganisms. Component vaccines contain only extracted or synthesised components of microorganisms (e.g. polysaccharides or proteins). Live vaccines contain organisms with attenuated (reduced) virulence, which cause only

## 6.11 Reasons for including an infectious disease on a regional/national list of reportable diseases\*

Reason for inclusion	Examples
<b>Endemic/local disease with the potential to spread and/or cause outbreaks</b>	Influenza, <i>Salmonella</i> , tuberculosis
<b>Imported disease with the propensity to spread and/or cause outbreaks</b>	Typhoid, cholera (depending on local epidemiology)
<b>Evidence of a possible breakdown in health protection/public health functions</b>	<i>Legionella</i> , <i>Cryptosporidium</i>
<b>Evidence of a possible breakdown in food safety practices</b>	Botulism, verotoxigenic <i>Escherichia coli</i>
<b>Evidence of a possible failure of a vaccination programme</b>	Measles, poliomyelitis, pertussis
<b>Disease with the potential to be a novel or increasing threat to human health</b>	COVID-19, MERS-CoV, multi-resistant bacteria
<b>Evidence of expansion of the range of a reservoir/vector</b>	Lyme disease, rabies, West Nile encephalitis
<b>Evidence of possible deliberate release</b>	Anthrax, tularaemia, plague, smallpox, botulism

\*Given the different geographical ranges of individual diseases and wide national variations in public health services, vaccination programmes and availability of resources, reporting regulations vary between regions, states and countries. Many diseases are reportable for more than one reason.  
(MERS-CoV = Middle East respiratory syndrome)

## 6.12 Pandemic response\*

- International travel restrictions
- National entry screening (e.g. testing for fever or pathogen) and quarantining new arrivals from areas with high infection rates
- Isolation of disease contacts
- Social isolation
- Shielding (strict separation of the vulnerable)
- Social distancing (maintaining physical separation between people and restricting public gatherings)
- Encouraging home working
- Restricting commuting and work-related travel to 'key workers' (workers required to maintain a functioning society)
- Home education
- Curfews
- Closure or reduction in public transport
- Requirement for PPE use in public areas (e.g. face coverings, eye protection)
- Litigation and imposition of legal sanctions to enforce the above responses

\*Pandemic control measures vary widely by jurisdiction and depend on the stage and extent of the outbreak and political considerations such as the acceptability of restriction of personal freedoms and the economic consequences of the interventions. See also p. 293.

mild symptoms but induce T-lymphocyte and humoral responses and are therefore more immunogenic than inactivated whole-cell vaccines. The use of live vaccines in immunocompromised individuals is not generally recommended, but they may be used by specialists following a risk/benefit assessment.

Component vaccines consisting only of polysaccharides, such as the pneumococcal polysaccharide vaccine (PPV), are poor activators of T lymphocytes and produce a short-lived antibody response without long-lasting memory. Conjugation of polysaccharide to a protein, as in the *Haemophilus influenzae* type B (Hib) vaccine and the protein conjugate pneumococcal vaccine (PCV), activates T lymphocytes, which results in a sustained response and immunological memory. Toxoids are bacterial toxins that have been modified to reduce toxicity but maintain antigenicity. Vaccine response can be improved by co-administration with mildly pro-inflammatory adjuvants, such as aluminium hydroxide.

i 6.13 Indications for post-exposure prophylaxis with immunoglobulins
<b>Human normal immunoglobulin (pooled immunoglobulin)</b>
<ul style="list-style-type: none"> <li>• Hepatitis A (unvaccinated contacts*)</li> <li>• Measles (exposed child with heart or lung disease)</li> </ul>
<b>Human specific immunoglobulin</b>
<ul style="list-style-type: none"> <li>• Hepatitis B (sexual partners, inoculation injuries, infants born to infected mothers)</li> <li>• Tetanus (high-risk wounds or incomplete or unknown immunisation status)</li> <li>• Rabies</li> <li>• Chickenpox (immunosuppressed children and adults, pregnant women)</li> </ul>
*Active immunisation is preferred if contact is with a patient who is within 1 week of onset of jaundice.

i 6.14 Vaccines in current clinical use
<b>Live attenuated vaccines</b>
<ul style="list-style-type: none"> <li>• Measles, mumps, rubella (MMR)</li> <li>• Oral poliomyelitis (OPV, not used in UK)</li> <li>• Rotavirus</li> <li>• Tuberculosis (bacille Calmette–Guérin, BCG)</li> <li>• Typhoid (oral typhoid vaccine)</li> <li>• Varicella zoster virus</li> </ul>
<b>Inactivated (killed) whole-cell vaccines</b>
<ul style="list-style-type: none"> <li>• Cholera</li> <li>• Hepatitis A</li> <li>• Influenza</li> <li>• Poliomyelitis (inactivated polio virus, IPV)</li> <li>• Rabies</li> </ul>
<b>Component vaccines</b>
<ul style="list-style-type: none"> <li>• Anthrax (adsorbed extracted antigens)</li> <li>• COVID-19</li> <li>• Diphtheria (adsorbed toxoid)</li> <li>• Hepatitis B (adsorbed recombinant hepatitis B surface antigen, HBsAg)</li> <li>• <i>Haemophilus influenzae</i> type B (conjugated capsular polysaccharide)</li> <li>• Human papillomavirus (recombinant capsid proteins)</li> <li>• Meningococcal, quadrivalent A, C, Y, W135 (conjugated capsular polysaccharide)</li> <li>• Meningococcal, serogroup C (conjugated capsular polysaccharide)</li> <li>• Pertussis (adsorbed extracted antigens)</li> <li>• Pneumococcal conjugate (PCV; conjugated capsular polysaccharide, 13 serotypes)</li> <li>• Pneumococcal polysaccharide (PPV; purified capsular polysaccharide, 23 serotypes)</li> <li>• Tetanus (adsorbed toxoid)</li> <li>• Typhoid (purified Vi capsular polysaccharide)</li> </ul>
<b>Viral vector vaccines</b>
<ul style="list-style-type: none"> <li>• Dengue virus (containing Yellow fever 17D vaccine strain with dengue virus genes)</li> <li>• Ebola virus (vesicular stomatitis virus expressing Ebola virus glycoproteins)</li> <li>• COVID-19</li> </ul>
<b>Nucleic acid vaccines</b>
<ul style="list-style-type: none"> <li>• COVID-19 (RNA vaccines)</li> <li>• Ebola virus (DNA in clinical trials)</li> </ul>

Recent and emerging vaccine approaches include nucleic acid (DNA or RNA)-based vaccines, in which the vaccine nucleic acid encodes the microbial component of interest; when the vaccine enters the vaccinee's cells they are induced to express viral antigens. They have several advantages over component vaccines: antigen is expressed for a period of time and with the modifications that the host cell would normally produce; antigen is presented by both major histocompatibility class I and II and induces broad B- and T-lymphocyte responses; vaccines are stable and cost-effective; production can be at large scale. DNA and RNA vaccines can be administered directly or may be added with other components to aid cell entry, e.g. liposomes for DNA vaccines or lipid nanoparticles for RNA vaccines. Long-term persistence and chromosomal integration with the potential for mutagenesis remain theoretical concerns for DNA vaccines.

Another approach is to use viral vectors in which an unrelated and modified virus expresses the antigen of interest. These vectors include pox viruses (e.g. modified vaccinia virus Ankara or canary pox virus), adenovirus or adeno-associated viruses. The vector may replicate or be non-replicating. These vaccines work on the same basis as DNA vaccines and are safe and stable. Pre-existing immunity can influence efficacy but use of rare human or related animal strains or a strategy of priming with a non-viral DNA vaccine can help overcome this ('prime-boost' strategy). Nucleic acid vaccines are administered intramuscularly or intradermally while viral vector vaccines can be given by these routes but also intranasally or orally. The first viral vector vaccine to receive clinical approval was for dengue virus, while to date DNA vaccines have only been used in veterinary settings. However, both strategies are employed in studies investigating a range of approaches against Ebola virus and pandemic infections. For COVID-19, vaccines in use or development include viral vectored, RNA, DNA, live attenuated, inactivated (killed) virus, subunit and virus-like particle (lacking genetic material) vaccines. The first types to be used widely were mRNA and adenovirus vector RNA vaccines (see [Box 13.38](#)).

### Use of vaccines

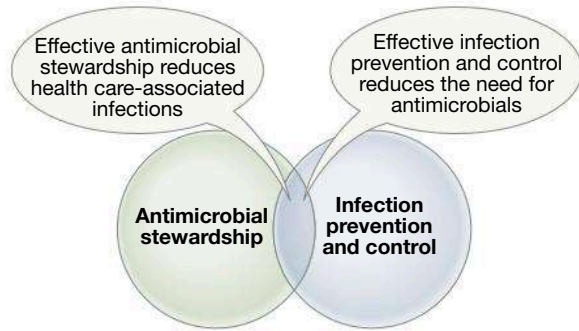

Vaccination may be applied to entire populations or to subpopulations at specific risk through travel, occupation or other activities. In ring vaccination, the population immediately surrounding a case or outbreak of infectious disease is vaccinated to curtail further spread. This strategy has been used for Ebola in West Africa. Vaccination is aimed mainly at preventing infectious disease. However, vaccination against human papillomavirus (HPV) was introduced to prevent cervical and other cancers that complicate HPV infection. Vaccination guidelines for individuals are shown in [Box 6.15](#).

Vaccination becomes successful for a population once the number of susceptible hosts falls below the level required to sustain continued transmission of the target organism, i.e. when  $R_0$  is less than 1 ('herd immunity'). Naturally acquired smallpox was declared to have been eradicated worldwide in 1980 through mass vaccination. In 1988, the WHO resolved to eradicate poliomyelitis by vaccination; the number of cases of wild polio virus infection worldwide has since fallen from approximately 350 000 per annum to 176 in 2019. Recommended vaccination schedules, including catch-up schedules for people who join vaccination programmes late, vary between countries.

## Antimicrobial stewardship

Antimicrobial stewardship (AMS) refers to the systems and processes applied to a population to optimise the use of antimicrobial agents. The populations referred to here may be a nation, region, hospital, or a unit within a health-care organisation (e.g. ward or clinic). AMS aims to improve patient outcomes and reduce antimicrobial resistance (AMR). IPC and AMS complement each other ([Fig. 6.14](#)). Elements of AMS include treatment guidelines, antimicrobial formularies and ward rounds by infection specialists.

i 6.15 Guidelines for vaccination against infectious disease
<ul style="list-style-type: none"> <li>• The principal contraindication to inactivated vaccines is an anaphylactic reaction to a previous dose or a vaccine component</li> <li>• Live vaccines should not be given during an acute infection, to pregnant women or to the immunosuppressed, unless the immunosuppression is mild and the benefits outweigh the risks</li> <li>• If two live vaccines are required, they should be given either simultaneously in opposite arms or 4 weeks apart</li> <li>• Live vaccines should not be given for 3 months after an injection of human normal immunoglobulin (HNI)</li> <li>• HNI should not be given for 2 weeks after a live vaccine</li> <li>• Hay fever, asthma, eczema, sickle-cell disease, topical glucocorticoid therapy, antibiotic therapy, prematurity and chronic heart and lung diseases, including tuberculosis, are not contraindications to vaccination</li> </ul>

**Fig. 6.14** The relationship between infection prevention and control (IPC) and antimicrobial stewardship (AMS).

## Treatment of infectious diseases

Key components of treating infection are:

- prompt initiation of antimicrobial therapy in severe infections, e.g. sepsis, meningitis
- optimising antimicrobial therapy while minimising selection for antimicrobial resistance and the impact on the normal microbial flora
- addressing predisposing factors, e.g. glycaemic control in diabetes mellitus; viral load control in HIV-1 infection
- achieving source control, e.g. removal of an infected medical device, pus or necrotic tissue
- managing complications, e.g. sepsis and acute kidney injury.

For communicable disease, treatment must also take into account contacts of the infected patient, and may include IPC interventions such as isolation, antimicrobial prophylaxis, vaccination and contact tracing.

## Principles of antimicrobial therapy

In some situations (e.g. pneumonia, meningitis, sepsis) it is important to start appropriate antimicrobial therapy promptly, whereas in others prior confirmation of the diagnosis and pathogen is preferred. The principles underlying the choice of antimicrobial agent(s) are discussed below. The WHO 'World Antibiotic Awareness Week' campaign is a yearly event aimed at highlighting the importance of prudent antimicrobial prescribing (see 'Further information').

### Antimicrobial action and spectrum

Antimicrobial agents may kill or inhibit microorganisms by targeting essential and non-essential cellular processes, respectively. The range, or spectrum, of microorganisms that is killed or inhibited by a particular antimicrobial agent needs consideration when selecting therapy. Mechanisms of action of the major classes of antibacterial agent are listed in [Box 6.16](#) and appropriate agents for some common infecting organisms are shown in [Box 6.17](#). In severe infections and/or immunocompromised patients, it is customary to use bactericidal agents in preference to bacteriostatic agents.

### Empiric versus targeted therapy

Empiric antimicrobial therapy is selected to treat a suspected infection (e.g. meningitis) before the microbiological cause is known. Targeted or 'directed' therapy can be prescribed when the pathogen(s) is known. Empirical antimicrobial regimens need to have activity against the range of pathogens potentially causing the infection; because broad-spectrum agents affect a wide range of bacteria they select for antimicrobial resistance. 'Start Smart – Then Focus' ([Fig. 6.15](#)) describes the principle of converting from empiric therapy to narrow-spectrum targeted therapy. Optimum empiric therapy depends on the site of infection,

### 6.16 Target and mechanism of action of common antibacterial agents

<b>Aminoglycosides, chloramphenicol, macrolides, lincosamides, oxazolidinones</b>
• Inhibition of bacterial protein synthesis by binding to subunits of bacterial ribosomes
<b>Tetracyclines</b>
• Inhibition of protein synthesis by preventing transfer RNA binding to ribosomes
<b><math>\beta</math>-lactams</b>
• Inhibition of cell wall peptidoglycan synthesis by competitive inhibition of transpeptidases ('penicillin-binding proteins')
<b>Cyclic lipopeptide (daptomycin)</b>
• Insertion of lipophilic tail into plasma membrane causing depolarisation and cell death
<b>Fluoroquinolones</b>
• Inhibition of DNA replication by binding to DNA topoisomerases (DNA gyrase and topoisomerase IV), preventing supercoiling and uncoiling of DNA
<b>Glycopeptides</b>
• Inhibition of cell wall peptidoglycan synthesis by forming complexes with D-alanine residues on peptidoglycan precursors
<b>Nitroimidazoles</b>
• The reduced form of the drug causes strand breaks in DNA
<b>Rifamycins</b>
• Inhibition of RNA synthesis by inhibiting DNA-dependent RNA polymerase
<b>Sulphonamides and trimethoprim</b>
• Inhibition of folate synthesis by dihydropteroate synthase (sulphonamides) and dihydrofolate reductase (trimethoprim) inhibition

patient characteristics and local antimicrobial resistance patterns. National or local guidelines should inform antimicrobial prescribing decisions.

### Combination therapy

It is sometimes appropriate to combine antimicrobial agents:

- when there is a need to increase clinical effectiveness (e.g. biofilm infections)
- when no single agent's spectrum covers all potential pathogens (e.g. polymicrobial infection)
- when there is a need to reduce development of antimicrobial resistance in the target pathogen, as the organism would need to develop resistance to multiple agents simultaneously (e.g. antituberculous chemotherapy and antiretroviral therapy (ART) for HIV).

### Antimicrobial resistance

Microorganisms have evolved in the presence of naturally occurring antibiotics and have therefore developed resistance mechanisms to all classes of antimicrobial agent (antibiotics and their derivatives) ([Fig. 6.16](#)). Intrinsic resistance is an innate property of a microorganism, whereas acquired resistance arises by spontaneous mutation or horizontal transfer of genetic material from another organism, usually via a plasmid. Plasmids can be easily transferred between bacteria (especially *Enterobacteriales*) and often encode resistance to multiple antibiotics.

Penicillin-binding proteins (PBP) are enzymes involved in bacterial cell wall synthesis. The *mecA* gene encodes a PBP, which has a low affinity for penicillins and therefore confers resistance to  $\beta$ -lactam antibiotics in staphylococci. Extended-spectrum  $\beta$ -lactamases (ESBLs) are bacterial-produced enzymes that break down  $\beta$ -lactam antibiotics, and are frequently encoded on plasmids in *Enterobacteriales*. Plasmid-encoded carbapenemases have been detected in strains of *Klebsiella pneumoniae* (e.g. New Delhi metallo- $\beta$ -lactamase 1, NDM-1). Strains of MRSA have been described that also have reduced susceptibility to glycopeptides through the development of a relatively impermeable cell wall.

## 6.17 Antimicrobial options for common infecting bacteria

Organism	Antimicrobial options*
<b>Gram-positive organisms</b>	
<i>Enterococcus faecalis</i>	Ampicillin, vancomycin/teicoplanin
<i>Enterococcus faecium</i>	Vancomycin/teicoplanin, linezolid
Glycopeptide-resistant enterococci	Linezolid, tigecycline, daptomycin
MRSA	Clindamycin, vancomycin, rifampicin (never used as monotherapy), linezolid, daptomycin, tetracyclines, tigecycline, co-trimoxazole
<i>Staphylococcus aureus</i>	Flucloxacillin, clindamycin
<i>Streptococcus pyogenes</i>	Penicillin, clindamycin, vancomycin
<i>Streptococcus pneumoniae</i>	Penicillin, cephalosporins, levofloxacin, vancomycin
<b>Gram-negative organisms</b>	
<i>E. coli</i> , 'coliforms' (enteric Gram-negative bacilli)	Amoxicillin, trimethoprim, cefuroxime, ciprofloxacin, co-amoxiclav
<i>Enterobacter</i> spp., <i>Citrobacter</i> spp.	Ciprofloxacin, meropenem, ertapenem, aminoglycosides
ESBL-producing <i>Enterobacterales</i>	Ciprofloxacin, meropenem, ertapenem (if sensitive), temocillin, aminoglycosides
Carbapenemase-producing <i>Enterobacterales</i>	Ciprofloxacin, aminoglycosides, tigecycline, colistin
<i>Haemophilus influenzae</i>	Amoxicillin, co-amoxiclav, macrolides, cefuroxime, cefotaxime, ciprofloxacin
<i>Legionella pneumophila</i>	Azithromycin, levofloxacin, doxycycline
<i>Neisseria gonorrhoeae</i>	Ceftriaxone/cefixime, spectinomycin
<i>Neisseria meningitidis</i>	Penicillin, cefotaxime/ceftriaxone, chloramphenicol
<i>Pseudomonas aeruginosa</i>	Ciprofloxacin, piperacillin–tazobactam, aztreonam, meropenem, aminoglycosides, ceftazidime/cefepime
<i>Salmonella typhi</i>	Ceftriaxone, azithromycin (uncomplicated typhoid), chloramphenicol (resistance common)
<b>Strict anaerobes</b>	
<i>Bacteroides</i> spp.	Metronidazole, clindamycin, co-amoxiclav, piperacillin–tazobactam, meropenem
<i>Clostridioides difficile</i>	Metronidazole, vancomycin (oral), fidaxomicin
<i>Clostridium</i> spp.	Penicillin, metronidazole, clindamycin
<i>Fusobacterium</i> spp.	Penicillin, metronidazole, clindamycin
<b>Other organisms</b>	
<i>Chlamydia trachomatis</i>	Azithromycin, doxycycline
<i>Treponema pallidum</i>	Penicillin, doxycycline

\*Antibiotic selection depends on multiple factors, including local susceptibility patterns, which vary enormously between geographical areas. There are many appropriate alternatives to those listed. (ESBL= extended-spectrum  $\beta$ -lactamase; MRSA = methicillin-resistant *Staphylococcus aureus*)

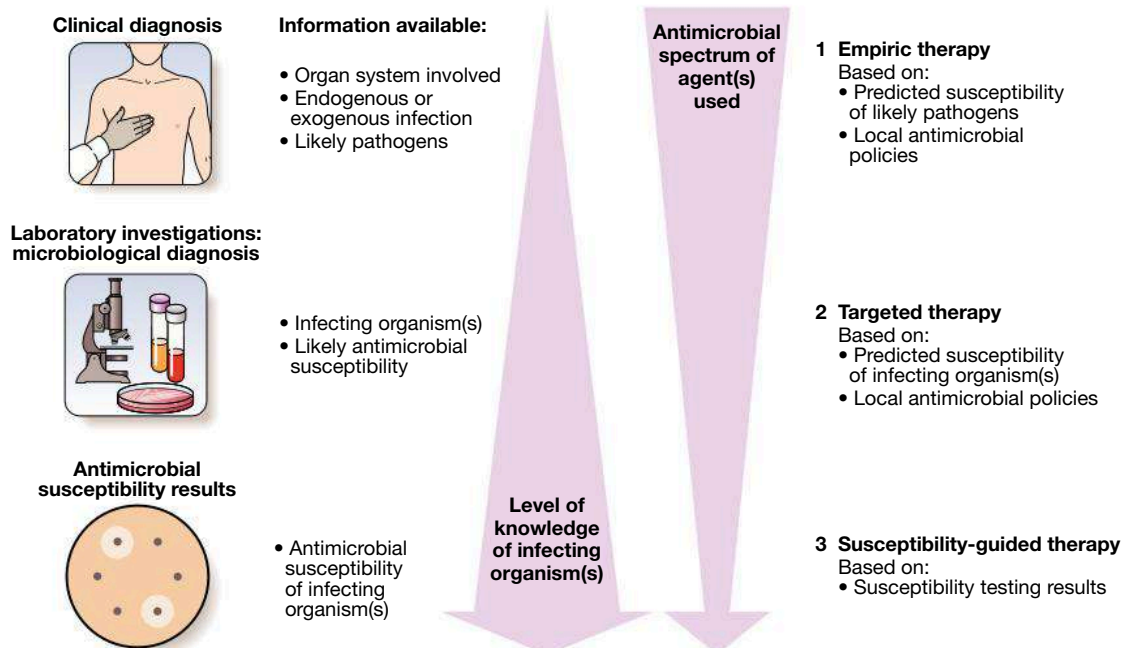

Fig. 6.15 Stages in the selection and refinement of antimicrobial therapy: 'Start Smart – Then Focus'.

**Fig. 6.16** Examples of mechanisms of antimicrobial resistance. (CAT = chloramphenicol acetyltransferase; ESBLs = extended-spectrum β-lactamases; MRSA = methicillin-resistant *Staph. aureus*; NDM-1 = New Delhi metallo-β-lactamase 1).

Factors promoting antimicrobial resistance include the inappropriate use of antibiotics (e.g. to treat viral infections), inadequate dosage or unnecessarily prolonged treatment, and use of antimicrobials as growth promoters in agriculture. However, any antimicrobial use exerts a selection pressure that favours the development of resistance. Combination antimicrobial therapy may reduce the emergence of resistance in the target pathogen but not in the normal flora that it also affects. Despite use of combination therapy for *M. tuberculosis*, multi-resistant tuberculosis (MDR-TB) and extremely drug-resistant tuberculosis (XDR-TB) have been reported worldwide and are increasing in incidence (see p. 524).

The term 'post-antibiotic era' was coined to describe a future in which widespread antimicrobial resistance will render antimicrobials useless. At present there is a gradual but inexorable progression of resistance globally, necessitating the use of more expensive antimicrobials or older antimicrobials with significant toxicity.

### Duration of therapy

Treatment duration reflects the severity of infection and accessibility of the infected site to antimicrobial agents. For most infections, there is limited evidence available to support a specific duration of treatment (Box 6.18). Depending on the indication, initial intravenous therapy can often be switched to oral as soon as the patient is afebrile and improving. In the absence of specific guidance, antimicrobial therapy should be stopped when there is no longer any clinical evidence of infection.

### Pharmacokinetics and pharmacodynamics

Pharmacokinetics of antimicrobial agents is the study of how antibiotics are absorbed, distributed and excreted from the body. Septic patients often have poor gastrointestinal absorption, so the preferred initial route of therapy is intravenous. Knowledge of anticipated antimicrobial drug

concentrations at sites of infection is critical. For example, achieving a 'therapeutic' blood level of gentamicin is of little practical use in treating meningitis, as CSF penetration of the drug is poor. Knowledge of routes of antimicrobial elimination is also critical; for instance, urinary tract infection is ideally treated with a drug that is excreted unchanged in the urine.

Pharmacodynamics describes the complex relationship between antimicrobial concentrations and microbial killing in the body. For many agents, antimicrobial effect can be categorised as 'concentration-dependent' or 'time-dependent'. The concentration of antimicrobial achieved after a single dose is illustrated in Figure 6.17. The maximum concentration achieved is  $C_{max}$  and the measure of overall exposure is the area under the curve (AUC). The efficacy of antimicrobial agents whose killing is concentration-dependent (e.g. aminoglycosides) increases with the amount by which  $C_{max}$  exceeds the minimum inhibitory concentration ( $C_{max}$ :MIC ratio). For this reason, it has become customary to administer aminoglycosides (e.g. gentamicin) infrequently at high doses (e.g. 7 mg/kg) rather than frequently at low doses. This has the added advantage of minimising toxicity by reducing the likelihood of drug accumulation. Conversely, the β-lactam antibiotics and vancomycin exhibit time-dependent killing, and their efficacy depends on  $C_{max}$  exceeding the MIC for a certain time (which is different for each class of agent). This is reflected in the dosing interval of benzylpenicillin, which is usually given every 4 hours in severe infection (e.g. meningococcal meningitis), and may be administered by continuous infusion. For other antimicrobial agents, the pharmacodynamic relationships are more complex and often less well understood. With some agents, bacterial inhibition persists after antimicrobial exposure (post-antibiotic and post-antibiotic sub-MIC effects).

### Therapeutic drug monitoring

Therapeutic drug monitoring is used to confirm that levels of antimicrobial agents with a low therapeutic index (e.g. aminoglycosides) are not

6.18 Duration of antimicrobial therapy for some common infections*	
Infection	Duration of therapy
<b>Viral infections</b>	
Herpes simplex encephalitis	2–3 weeks
<b>Bacterial infections</b>	
Gonorrhoea	Single dose
Infective endocarditis (streptococcal, native valve)	4 weeks ± gentamicin for first 2 weeks
Infective endocarditis (prosthetic valve)	6 weeks
Osteomyelitis	6 weeks
Pneumonia (community-acquired, severe)	7–10 days (no organism identified), 14–21 days ( <i>Staphylococcus aureus</i> or <i>Legionella</i> spp.)
Septic arthritis	2–4 weeks
Urinary tract infection (male)	1–2 weeks depending on severity
Urinary tract infection, upper tract, uncomplicated (female)	7 days
Urinary tract infection, lower (female)	3 days
<b>Mycobacterial infections</b>	
Tuberculosis (meningeal)	12 months
Tuberculosis (pulmonary)	6 months
<b>Fungal infections</b>	
Invasive pulmonary aspergillosis	Until clinical/radiological resolution and reversal of predisposition
Candidaemia (acute disseminated)	2 weeks after last positive blood culture and resolution of signs and symptoms

\*All recommendations are indicative. Actual duration takes into account predisposing factors, specific organisms and antimicrobial susceptibility, source control, current guidelines and clinical response.

**Fig. 6.17 Antimicrobial pharmacodynamics.** The curve represents drug concentrations after a single dose of an antimicrobial agent. Factors that determine microbial killing are  $C_{max} : MIC$  ratio (concentration-dependent killing), time above MIC (time-dependent killing) and AUC:MIC ratio.

excessive, and that levels of agents with marked pharmacokinetic variability (e.g. vancomycin) are adequate. Specific recommendations for monitoring depend on individual clinical circumstances; for instance, different pre- and post-dose levels of gentamicin are recommended,

6.19 Recommendations for antimicrobial prophylaxis in adults*	
Infection risk	Recommended antimicrobial
<b>Bacterial</b>	
Diphtheria (prevention of secondary cases)	Erythromycin
Gas gangrene (after high amputation or major trauma)	Penicillin or metronidazole
Lower gastrointestinal tract surgery	Cefuroxime + metronidazole, gentamicin + metronidazole, or co-amoxiclav (single dose only)
Meningococcal disease (prevention of secondary cases)	Rifampicin or ciprofloxacin
Rheumatic fever (prevention of recurrence)	Phenoxymethylpenicillin or sulfadiazine
Tuberculosis (prevention of secondary cases)	Isoniazid ± rifampicin
Whooping cough (prevention of secondary cases)	Erythromycin
<b>Viral</b>	
HIV, occupational exposure (sharps injury)	Combination tenofovir/emtricitabine and raltegravir. Modified if index case's virus known to be resistant
Influenza A (prevention of secondary cases in adults with chronic respiratory, cardiovascular or renal disease, immunosuppression or diabetes mellitus)	Oseltamivir
<b>Fungal</b>	
Aspergillosis (in high-risk haematology patients)	Posaconazole (voriconazole or itraconazole alternatives if intolerant)
<i>Pneumocystis</i> pneumonia (prevention in HIV and other immunosuppressed states)	Co-trimoxazole, pentamidine or dapsone
<b>Protozoal</b>	
Malaria (prevention of travel-associated disease)	Specific antimalarials depend on travel itinerary. Specialist guidance should be consulted

\*These are based on current UK practice. Recommendations may vary locally or nationally. Antimicrobial prophylaxis for infective endocarditis during dental procedures is not currently recommended in the UK.

depending on whether it is being used in traditional divided doses, once daily or for synergy in infective endocarditis (p. 462).

## Antimicrobial prophylaxis

Antimicrobial prophylaxis is the use of antimicrobial agents to prevent infection. Primary prophylaxis is used to reduce the risk of infection following certain medical procedures (e.g. colonic resection or prosthetic hip insertion), following exposure to a specific pathogen (e.g. *Bordetella pertussis*) or in specific situations such as post-splenectomy (Box 6.19). Antimicrobial prophylaxis should be chosen to have minimal adverse effects and based on robust evidence. In the case of exposure, it may be combined with passive immunisation (see Box 6.13). Secondary prophylaxis is used in patients who have been treated successfully for an infection but remain predisposed to it. It is used in haemato-oncology patients in the context of fungal infection and in HIV-positive individuals with an opportunistic infection until a defined level of immune reconstitution is achieved.

## Antibacterial agents

For details of antibacterial usage in pregnancy and old age, see Boxes 6.20 and 6.21.

## 6.20 Antimicrobial agents in pregnancy<sup>1</sup>

### Contraindicated

- Chloramphenicol: neonatal 'grey baby' syndrome – collapse, hypotension and cyanosis
- Fluconazole: teratogenic in high doses
- Quinolones: arthropathy in animal studies
- Sulphonamides: neonatal haemolysis and methaemoglobinaemia
- Tetracyclines, glycolycyclines: skeletal abnormalities in animals in first trimester; fetal dental discoloration and maternal hepatotoxicity with large parenteral doses in second or third trimesters
- Trimethoprim: teratogenic in first trimester
- Macrolides<sup>2</sup>: major malformations in first trimester and genital malformations any trimester

### Relatively contraindicated

- Aminoglycosides: potential damage to fetal auditory and vestibular nerves in second and third trimesters
- Metronidazole: avoidance of high dosages is recommended<sup>3</sup>

### Not known to be harmful; use only when necessary

- Aciclovir
- Penicillins and cephalosporins
- Clindamycin
- Glycopeptides
- Linezolid
- Meropenem

## 6.21 Problems with antimicrobial therapy in old age

- ***Clostridioides difficile* infection:** all antibiotics predispose to some extent, but second- and third-generation cephalosporins, co-amoxiclav and clindamycin especially so.
- **Hypersensitivity reactions:** rise in incidence due to increased previous exposure.
- **Renal impairment:** may be significant in old age, despite creatinine levels being within the reference range.
- **Nephrotoxicity:** more likely, e.g. aminoglycosides.
- **Accumulation of  $\beta$ -lactam antibiotics:** may result in myoclonus, seizures or coma.
- **Reduced gastric acid production:** gastric pH is higher, which causes increased penicillin absorption.
- **Reduced hepatic metabolism:** results in a higher risk of isoniazid-related hepatotoxicity.
- **Quinolones:** associated with delirium and may increase the risk of seizures.

## $\beta$ -lactam antibiotics

These antibiotics have a  $\beta$ -lactam ring structure and exert a bactericidal action by inhibiting PBPs and cell wall synthesis. They are classified in [Box 6.22](#).

### Pharmacokinetics

- Good drug levels are achieved in lung, kidney, bone, muscle and liver, and in pleural, synovial, pericardial and peritoneal fluids.
- CSF levels are low, except when meninges are inflamed.
- 'Inoculum effect': the activity of  $\beta$ -lactams is reduced in the presence of a high organism burden, although the clinical relevance of this effect is a subject of debate.
- Generally safe in pregnancy (except imipenem/cilastatin).

### Adverse effects

Immediate (IgE-mediated) allergic reactions are rare but life-threatening. Approximately 90% of patients who report a penicillin allergy do not have a true IgE-mediated allergy, highlighting the importance of careful allergy histories and documentation of reactions. Other reactions, such as rashes, fever and haematological effects (e.g. low white cell count), usually follow more prolonged therapy (more than 2 weeks). Patients with

## i

## 6.22 $\beta$ -lactam antibiotics

### Penicillins

- Natural penicillins: benzylpenicillin, phenoxymethylpenicillin
- Penicillinase-resistant penicillins: methicillin\*, flucloxacillin, nafcillin, oxacillin
- Aminopenicillins: ampicillin, amoxicillin
- Carboxy- and ureido-penicillins: ticarcillin, piperacillin, temocillin

### Cephalosporins

- See [Box 6.23](#)

### Monobactams

- Aztreonam

### Carbapenems

- Imipenem, meropenem, ertapenem, doripenem

\*Not used for treatment.

infectious mononucleosis may develop a rash if given aminopenicillins; this does not imply lasting allergy. The relationship between allergy to penicillin and allergy to cephalosporins depends on the specific cephalosporin used. Avoidance of cephalosporins, however, is recommended in patients who have IgE-mediated penicillin allergy (p. 80). Cross-reactivity between penicillin and carbapenems is rare (approximately 1% by skin testing) and carbapenems may be administered if there are no suitable alternatives and appropriate resuscitation facilities are available.

Gastrointestinal upset and diarrhoea are common, and a mild reversible hepatitis is recognised with many  $\beta$ -lactams. More severe forms of hepatitis can be observed with flucloxacillin and co-amoxiclav. Leucopenia, thrombocytopenia, coagulation deficiencies, interstitial nephritis and potentiation of aminoglycoside-mediated kidney damage are also recognised. Seizures and encephalopathy have been reported, particularly with high doses in the presence of renal insufficiency. Thrombophlebitis occurs in up to 5% of patients receiving parenteral  $\beta$ -lactams.

### Drug interactions

Synergism occurs in combination with aminoglycosides *in vitro*. Ampicillin decreases the biological effect of oral contraceptives and the whole class is significantly affected by concurrent administration of probenecid, producing a 2–4-fold increase in the peak serum concentration.

### Penicillins

Natural penicillins are primarily effective against Gram-positive organisms (except staphylococci, most of which produce a penicillinase) and anaerobic organisms. *Streptococcus pyogenes* has remained sensitive to natural penicillins worldwide. According to the European Antimicrobial Resistance Surveillance Network (EARS-Net), the prevalence of non-susceptibility to penicillin in *Streptococcus pneumoniae* in Europe in 2018 varied widely from 0.1% (Belgium) to 40% (Romania).

Penicillinase-resistant penicillins are the mainstay of treatment for infections with *Staph. aureus*, other than MRSA. However, EARS-Net data from 2018 indicate that MRSA rates in Europe vary widely from 0% (Iceland) to 43% (Romania).

Aminopenicillins have the same spectrum of activity as the natural penicillins, with additional Gram-negative cover against *Enterobacterales*. Amoxicillin has better oral absorption than ampicillin. Unfortunately, resistance to these agents is widespread (*Escherichia coli* Europe-wide in 2018, range 35.3%–67.6%), so they are no longer appropriate for empiric use in Gram-negative infections. In many organisms, resistance is due to  $\beta$ -lactamase production, which can be overcome by the addition of  $\beta$ -lactamase inhibitors (clavulanic acid or sulbactam).

Carboxypenicillins (e.g. ticarcillin) and ureidopenicillins (e.g. piperacillin) are particularly active against Gram-negative organisms, especially *Pseudomonas* spp., which are resistant to the aminopenicillins.  $\beta$ -lactamase inhibitors may be added to extend their spectrum of activity (e.g. piperacillin-tazobactam). Temocillin is derived from ticarcillin; it has good activity against *Enterobacterales*, including those that produce ESBL enzymes, but poor activity against *P. aeruginosa* and Gram-positive bacteria.

## Cephalosporins and cephamycins

Cephalosporins are broad-spectrum agents. Unfortunately, their use is associated with *C. difficile* infection. With the exception of ceftobiprole, the group has no activity against enterococci. Only the cephamycins have anti-anaerobic activity. All cephalosporins are inactivated by ESBL. Cephalosporins are arranged in 'generations' (Box 6.23).

- *First-generation compounds* have excellent activity against Gram-positive organisms and some activity against Gram-negatives.
- *Second-generation drugs* retain Gram-positive activity but have extended Gram-negative activity. Cephamycins (e.g. cefoxitin), included in this group, are active against anaerobic Gram-negative bacilli.
- *Third-generation agents* have improved anti-Gram-negative coverage. For some (e.g. ceftazidime), this is extended to include *Pseudomonas* spp. Cefotaxime and ceftriaxone have excellent Gram-negative activity and retain good activity against *Strep. pneumoniae* and  $\beta$ -haemolytic streptococci. Ceftriaxone is administered once daily and is therefore a suitable agent for outpatient intravenous (parenteral) antimicrobial therapy (OPAT).
- *Fourth-generation agents*, e.g. cefepime, have a broad spectrum of activity, including streptococci and some Gram-negatives, including *P. aeruginosa*.
- *Fifth-generation agents*, such as ceftobiprole and ceftaroline, have an enhanced spectrum of Gram-positive activity that includes MRSA, and also have activity against Gram-negative bacteria; some, such as ceftobiprole, are active against *P. aeruginosa*.
- Cefiderocol is a novel siderophore cephalosporin, which is also active in the presence of ESBLs and carbapenemases.

The spectrum of cephalosporins has also been enhanced by adding  $\beta$ -lactamase inhibitors, e.g. ceftazidime/avibactam and ceftolazone/tazobactam.

## Monobactams

Aztreonam is the only available monobactam. It is active against Gram-negative bacteria, except ESBL-producing organisms, but inactive against Gram-positive organisms or anaerobes. It is a parenteral-only agent and may be used safely in most penicillin-allergic patients other than those with an allergy to ceftazidime, which shares a common side chain.

## Carbapenems

These intravenous agents have the broadest antibiotic activity of the  $\beta$ -lactam antibiotics, covering most clinically significant bacteria, including anaerobes (e.g. imipenem, meropenem, ertapenem). Carbapenems

are also being combined with  $\beta$ -lactamase inhibitors in response to emergence of carbapenemase enzymes that inactivate this class (e.g. meropenem-vaborbactam).

## Macrolide and lincosamide antibiotics

Macrolides (e.g. erythromycin, clarithromycin and azithromycin) and lincosamides (e.g. clindamycin) are bacteriostatic agents. Both classes bind to the same component of the ribosome, so they are not administered together. Macrolides are used for *Legionella*, *Mycoplasma*, *Chlamydia* and *Bordetella* infections. Azithromycin is employed for single-dose/short-course therapy for genitourinary *Chlamydia/Mycoplasma* spp. infections. Clindamycin is used primarily for skin, soft tissue, bone and joint infections.

### Pharmacokinetics

#### Macrolides

- Variable bioavailability (intravenous and oral preparations available).
- Frequency of administration: erythromycin is administered 4 times daily, clarithromycin twice daily, azithromycin once daily.
- High protein binding.
- Excellent intracellular accumulation.

#### Lincosamides (e.g. clindamycin)

- Good oral bioavailability.
- Food has no effect on absorption.
- Good bone/joint penetration; limited CSF penetration.

#### Adverse effects

- Gastrointestinal upset, especially in young adults (erythromycin 30%).
- Cholestatic jaundice with erythromycin estolate.
- Prolongation of QT interval can cause torsades de pointes (p. 418).
- Clindamycin predisposes to CDI.

## Aminoglycosides and spectinomycin

Aminoglycosides are effective mainly in Gram-negative infections and are therefore commonly used in regimens for intra-abdominal infection. Some aminoglycosides, e.g. amikacin, are important components of therapy for MDR-TB. Because they act synergistically with  $\beta$ -lactam antibiotics they are used in combinations to treat biofilm infections, including infective endocarditis and orthopaedic implant infections. They cause very little local irritation at injection sites and negligible allergic responses. Oto- and nephrotoxicity must be avoided by monitoring of renal function and drug levels and by use of short treatment regimens. Aminoglycosides are not subject to an inoculum effect and they all exhibit a post-antibiotic effect. Resistance is mediated mainly through inactivation by aminoglycoside-modifying enzymes (AMEs). Plazomicin is a novel aminoglycoside that is not yet inactivated by AMEs.

### Pharmacokinetics

- Negligible oral absorption.
- Hydrophilic, so excellent penetration to extracellular fluid in body cavities and serosal fluids, but poor penetration into adipose tissue.
- Very poor intracellular penetration (except hair cells in cochlea and renal cortical cells).
- Negligible CSF and corneal penetration.
- Peak plasma levels 30 minutes after infusion.
- Exhibit a post-antibiotic effect.
- Monitoring of therapeutic levels required.

### Gentamicin dosing

- Gentamicin should be dosed according to actual body weight or ideal body weight if obese.
- Except in certain forms of endocarditis, pregnancy, severe burns, end-stage renal disease and paediatric patients, gentamicin can be administered at 7 mg/kg body weight. The appropriate dose interval

6.23 Cephalosporins	
<b>First generation</b>	
• Cefalexin, cefradine (oral)	• Cefazolin (IV)
<b>Second generation</b>	
• Cefuroxime (oral/IV)	• Cefoxitin (IV)
• Cefaclor (oral)	
<b>Third generation</b>	
• Cefixime (oral)	• Ceftriaxone (IV)
• Cefotaxime (IV)	• Ceftazidime (IV)
<b>Fourth generation</b>	
• Cefepime (IV)	
<b>Fifth generation (also referred to as 'next generation')</b>	
• Ceftobiprole (IV)	• Ceftaroline (IV)
(IV = intravenous)	

**Fig. 6.18** Dosing of aminoglycosides using the Hartford nomogram. The nomogram is used to determine the dose interval for 7 mg/kg doses of gentamicin or tobramycin, using measurements of drug levels in plasma 6–14 hours after a single dose.

depends on drug clearance and is determined by reference to the Hartford nomogram (Fig. 6.18).

- In most other situations, gentamicin is usually administered twice or 3 times daily at 3–5 mg/kg/day with target pre- and post-dose levels of <1 mg/L and 5–10 mg/L.
- In streptococcal and enterococcal endocarditis, gentamicin is used with a cell wall active agent (usually a  $\beta$ -lactam), to provide synergy. Lower doses and target levels are used in this situation.
- For all aminoglycoside dosing local guidance should be consulted.

#### Adverse effects

- Renal toxicity (usually reversible) accentuated by other nephrotoxic agents.
- Cochlear toxicity (permanent) more likely in older people and those with a predisposing mitochondrial gene mutation.
- Neuromuscular blockade after rapid intravenous infusion (potentiated by calcium channel blockers, myasthenia gravis and hypomagnesaemia).

#### Spectinomycin

Chemically similar to the aminoglycosides and given intramuscularly, spectinomycin was developed to treat strains of *Neisseria gonorrhoeae* resistant to  $\beta$ -lactam antibiotics. Unfortunately, resistance to spectinomycin is very common. Its only indication is the treatment of gonococcal urethritis in pregnancy or in patients allergic to  $\beta$ -lactam antibiotics.

### Quinolones and fluoroquinolones

These are effective and generally well-tolerated bactericidal agents. The quinolones have purely anti-Gram-negative activity, whereas the fluoroquinolones are broad-spectrum agents (Box 6.24). Ciprofloxacin has anti-pseudomonal activity but resistance emerges rapidly. In 2018, European surveillance showed that resistance to fluoroquinolones in *E. coli* ranged between 8.4% (Finland) and 42.4% (Cyprus). Quinolones and fluoroquinolones are used for a variety of infections, including pyelonephritis, osteomyelitis and less common problems like MDR-TB.

#### Pharmacokinetics

- Well absorbed after oral administration but delayed by food, antacids, ferrous sulphate and multivitamins.
- Wide volume of distribution; tissue concentrations twice those in serum.
- Good intracellular penetration, concentrating in phagocytes.

### 6.24 Quinolones and fluoroquinolones

Agent	Route of administration	Typical antimicrobial spectrum
<b>Quinolones</b>		
Nalidixic acid	Oral	Enteric Gram-negative bacilli (not <i>Pseudomonas aeruginosa</i> )
<b>Fluoroquinolones</b>		
Ciprofloxacin	IV/oral	Enteric Gram-negative bacilli, <i>P. aeruginosa</i> , <i>Haemophilus</i> spp., 'atypical' respiratory pathogens*
Norfloxacin	Oral	
Ofloxacin	IV/oral/topical	
Levofloxacin (L-isomer of ofloxacin)	IV/oral	<i>Haemophilus</i> spp., <i>Streptococcus pneumoniae</i> , 'atypical' respiratory pathogens*
Moxifloxacin	Oral	<i>Strep. pneumoniae</i> , <i>Staphylococcus aureus</i> , 'atypical' respiratory pathogens,* mycobacteria and anaerobes
* 'Atypical' pathogens include <i>Mycoplasma pneumoniae</i> and <i>Legionella</i> spp. Fluoroquinolones have variable activity against <i>Mycobacterium tuberculosis</i> and other mycobacteria.		

#### Adverse effects

- Gastrointestinal side-effects in 1%–5%.
- Rare skin reactions (phototoxicity).
- Tendinitis and Achilles tendon rupture, especially in older people.
- Central nervous system effects (delirium, tremor, dizziness and occasional seizures in 5%–12%), especially in older people.
- Reduces clearance of xanthines and theophyllines, potentially inducing insomnia and increased seizure potential.
- Prolongation of QT interval on ECG, cardiac arrhythmias.
- Ciprofloxacin use is associated with acquisition of MRSA and strains of *C. difficile*.

### Glycopeptides

Glycopeptides (vancomycin and teicoplanin) are effective against Gram-positive organisms only, and are used mainly against staphylococci (including MRSA) and enterococci. Some staphylococci and enterococci are resistant, and glycopeptide use should be restricted to limit the emergence of resistance. Glycopeptides are not absorbed after oral administration but vancomycin is used orally to treat CDI.

Dalbavancin and telavancin are semisynthetic derivatives of glycopeptide (lipoglycopeptides). Dalbavancin is used primarily for skin and skin structure infections. Telavancin has a dual mechanism of action, inhibiting both cell wall synthesis and membrane polarisation; it is reserved for hospital-acquired pneumonia when other agents cannot be used.

#### Pharmacokinetics

- Vancomycin is administered by slow intravenous infusion. It has good tissue distribution and a short half-life, and enters the CSF only in the presence of inflammation. Therapeutic drug monitoring is recommended, to maintain pre-dose levels of >10 mg/L (15–20 mg/L in serious staphylococcal infections).
- Teicoplanin is administered intravenously or intramuscularly. Its long half-life allows once-daily dosing.
- Telavancin and dalbavancin are administered intravenously. Telavancin has a long half-life that allows once-daily dosing; dalbavancin has a very long half-life, allowing once-weekly dosing.

### Adverse effects

- Rapid infusion of vancomycin can cause histamine release ('red man' syndrome), although this is rare with modern preparations.
- Vancomycin and teicoplanin are associated with nephrotoxicity and ototoxicity.
- Vancomycin and teicoplanin can cause DRESS (drug reaction with eosinophilia and systemic symptoms, see [Box 27.35](#)).

## Lipopeptides

Daptomycin is a cyclic lipopeptide with bactericidal activity against Gram-positive organisms only, including MRSA and glycopeptide-resistant enterococci. It is not absorbed orally, and is used intravenously to treat Gram-positive infections, such as soft tissue infections and *Staph. aureus* infective endocarditis. Daptomycin is inactivated by pulmonary surfactant and is not effective for pneumonia. Treatment can be associated with increased levels of creatine kinase and eosinophilic pneumonitis.

## Polymyxins

Colistin is a polymyxin antibiotic that binds and disrupts the outer cell membrane of Gram-negative bacteria, including *P. aeruginosa* and *Acinetobacter baumannii*. Its use has increased with the emergence and spread of multi-resistant Gram-negative bacteria, including CPEs. It can be administered by oral, intravenous and nebulised routes. Significant adverse effects include neurotoxicity, including encephalopathy, and nephrotoxicity.

## Folate antagonists

These are bacteriostatic antibacterials. A combination of a sulphonamide and either trimethoprim or pyrimethamine is most commonly used, which interferes with two consecutive steps in the folate metabolic pathway. Available combinations include trimethoprim/sulfamethoxazole (co-trimoxazole) and pyrimethamine with either sulfadoxine (used to treat malaria) or sulfadiazine (used in toxoplasmosis). Co-trimoxazole is the first-line drug for *Pneumocystis jirovecii* infection, the second-line drug for treatment and prevention of *B. pertussis* infection, and is also used for a variety of other infections, including *Staph. aureus*. Dapsone is used to treat leprosy (Hansen's disease) and to prevent toxoplasmosis and pneumocystis when patients are intolerant of other medications. Folinic acid should be given to prevent myelosuppression if these drugs are used long-term or unavoidably in early pregnancy.

### Pharmacokinetics

- Well absorbed orally.
- Sulphonamides are hydrophilic, distributing well to the extracellular fluid.
- Trimethoprim is lipophilic with high tissue concentrations.

### Adverse effects

- Trimethoprim is generally well tolerated, with few adverse effects.
- Sulphonamides and dapsone may cause haemolysis in glucose-6-phosphate dehydrogenase deficiency.
- Sulphonamides and dapsone cause skin and mucocutaneous reactions, including Stevens-Johnson syndrome and 'dapsone syndrome' (rash, fever and lymphadenopathy).
- Dapsone causes methaemoglobinaemia and peripheral neuropathy.

## Tetracyclines and glycyclines

### Tetracyclines

Of this mainly bacteriostatic class, the newer drugs doxycycline and minocycline show better absorption and distribution than older ones. Resistance is common in streptococci and Gram-negative bacteria. Tetracyclines are indicated for infections caused by *Mycoplasma* spp., *Chlamydia* spp., *Rickettsia* spp., *Coxiella* spp., *Bartonella* spp., *Borrelia*

spp., *Helicobacter pylori*, *Treponema pallidum* and atypical mycobacteria. Tetracyclines can also be used for malaria prevention.

### Pharmacokinetics

- Best oral absorption is in the fasting state (doxycycline is 100% absorbed unless gastric pH rises) and absorption is inhibited by cations, e.g. calcium or iron, which should not be administered at the same time.

### Adverse effects

- All tetracyclines except doxycycline are contraindicated in renal failure.
- Dizziness with minocycline.
- Binding to metallic ions in bones and teeth causes discoloration (avoid in children and pregnancy) and enamel hypoplasia.
- Oesophagitis/oesophageal ulcers with doxycycline.
- Phototoxic skin reactions.

### Glycyclines (tigecycline)

Chemical modification of tetracycline has produced tigecycline, a broad-spectrum, parenteral-only antibiotic with activity against resistant Gram-positive and Gram-negative pathogens, such as MRSA and ESBL (but excluding *Pseudomonas* spp.). Re-analysis of trial data has shown that there was excess mortality following tigecycline treatment as opposed to comparator antibiotics, so tigecycline should be used only when there has been adequate assessment of risk versus benefit.

## Nitroimidazoles

Nitroimidazoles (e.g. metronidazole) are highly active against strictly anaerobic bacteria, especially *Bacteroides fragilis*, *C. difficile* and *Clostridium* spp. Both metronidazole and tinidazole have significant anti-protozoal activity against amoebae and *Giardia lamblia*. Nitroimidazoles are almost completely absorbed after oral administration (60% after rectal administration) and well distributed, especially to brain and CSF. They can be used in pregnancy after a risk assessment.

Adverse effects include: metallic taste (dose-dependent), severe vomiting if taken with alcohol ('Antabuse effect') and peripheral neuropathy with prolonged use.

## Phenicol (chloramphenicol)

Chloramphenicol use is best reserved for severe and life-threatening infections when other antibiotics are either unavailable or impractical, due to toxicity. It is bacteriostatic to most organisms and has a very broad spectrum of activity against aerobic and anaerobic organisms. It competes with macrolides and lincosamides for ribosomal binding sites, so should not be used in combination with these agents. Significant adverse effects are 'grey baby' syndrome in infants (cyanosis and circulatory collapse due to inability to conjugate drug and excrete the active form in urine); reversible dose-dependent bone marrow depression in adults receiving high cumulative doses; and severe aplastic anaemia in 1 in 25 000–40 000 exposures (unrelated to dose, duration of therapy or route of administration).

## Oxazolidinones

Linezolid and tedizolid are examples and have good activity against Gram-positive organisms. They are primarily used in infection caused by resistant Gram-positive bacteria, including MRSA and GRE, but also for resistant *Mycobacterium tuberculosis*. Administration can be intravenous or oral. Common linezolid adverse effects include mild gastrointestinal upset and tongue discoloration. Myelodysplasia and peripheral and optic neuropathy can occur with prolonged use. Linezolid has monoamine oxidase inhibitor (MAOI) activity, and co-administration with other MAOIs or serotonin re-uptake inhibitors should be avoided, as this may precipitate a 'serotonin syndrome'.

## Other antibacterial agents

### Fusidic acid

This antibiotic, active against Gram-positive bacteria, is available in intravenous, oral or topical formulations. It is lipid-soluble and distributes well to tissues. Its antibacterial activity is, however, unpredictable. Fusidic acid is used in combination, typically with antistaphylococcal penicillins, or for MRSA with clindamycin or rifampicin. It interacts with coumarin derivatives and oral contraceptives.

### Nitrofurantoin

This drug has very rapid renal elimination and is active against aerobic Gram-negative and Gram-positive bacteria, including enterococci. It is used only for treatment of lower urinary tract infection, being generally safe in pregnancy and childhood. With prolonged treatment, however, it can cause eosinophilic lung infiltrates, fever, pulmonary fibrosis, peripheral neuropathy, hepatitis and haemolytic anaemia so its use must be carefully balanced against risks.

### Fidaxomicin

Fidaxomicin is an RNA synthesis inhibitor, and was introduced for the treatment of CDI in 2012. The registration trial found fidaxomicin was non-inferior to oral vancomycin in non-severe CDI and was associated with a lower recurrence rate. Its effectiveness for severe CDI has not been assessed in trials.

### Fosfomycin

Fosfomycin acts by inhibiting cell wall synthesis. It has activity against Gram-negative and Gram-positive bacteria and can demonstrate in vitro synergy against MRSA when combined with other antimicrobials. It is used for treatment of urinary tract infections but can be employed in other situations against multi-resistant bacteria.

### Lefamulin

Lefamulin is a pleuromutilin antibiotic that inhibits the 50S ribosome and inhibits protein synthesis. It has recently been licensed for use in community-acquired pneumonia and is available orally and intravenously. It should not be used in pregnancy and prolongs the QT interval.

## Antimycobacterial agents

### Isoniazid

Isoniazid is bactericidal for replicating bacteria and bacteriostatic for non-replicating bacteria. It is activated by mycobacterial catalase-peroxidase (KatG) and inhibits the *InhA* gene product, a reductase involved in mycolic acid synthesis. Mutations in *KatG* or *InhA* result in isoniazid resistance, which was reported in 15% of cases of *M. tuberculosis* infection globally in 2013. Isoniazid is well absorbed orally and metabolised by acetylation in the liver. The major side-effects are hepatitis, neuropathy (ameliorated by co-administration of pyridoxine) and hypersensitivity reactions.

### Rifampicin

Rifampicin inhibits DNA-dependent RNA polymerase and is bactericidal against replicating bacteria. It is also active in necrotic foci, where mycobacteria have low levels of replication, and is therefore important in sterilisation and sputum conversion. Resistance most often involves the  $\beta$ -subunit of RNA polymerase and most often occurs with isoniazid-resistant MDR-TB. Rifampicin is well absorbed orally. It is metabolised by the liver via the microsomal cytochrome P450 system and is one of the most potent inducers of multiple P450 isoenzymes, so is subject to extensive drug–drug interactions. Common side-effects include hepatitis, influenza-like symptoms and hypersensitivity reactions. Orange discoloration of urine and body secretions is expected.

### Pyrazinamide

The mechanism of action of pyrazinamide is incompletely defined but includes inhibition of fatty acid synthase and ribosomal trans-translation,

a quality control system for mRNA and protein synthesis. Pyrazinamide is often bacteriostatic but can be bactericidal and is active against semi-dormant bacteria in a low-pH environment. Primary resistance is rare but MDR-TB strains are frequently pyrazinamide-resistant and intrinsic resistance is a feature of *Mycobacterium bovis* strains. Pyrazinamide is well absorbed orally and metabolised by the liver. Side-effects include nausea, hepatitis, asymptomatic elevation of uric acid and myalgia.

### Ethambutol

Ethambutol is a bacteriostatic agent. It inhibits arabinosyl transferase, which is involved in the synthesis of arabinogalactan, a component of the mycobacterial cell wall. Resistance is usually seen when resistance to other antimycobacterial agents is also present, e.g. in MDR-TB strains. It is orally absorbed but, in contrast to the first-line agents described above, it achieves poor CSF penetration and is renally excreted. The major side-effect is optic neuritis with loss of red–green colour discrimination and impaired visual acuity.

### Streptomycin

Streptomycin is an aminoglycoside whose mechanism of action and side-effects are similar to those of other aminoglycosides. It is administered intramuscularly.

### Other antituberculous agents

Second-line agents used in MDR or XDR strains (p. 524) include aminoglycosides (amikacin, capreomycin or kanamycin) and fluoroquinolones (moxifloxacin or levofloxacin), discussed above. Other established second-line agents administered orally are cycloserine (which causes neurological side-effects); ethionamide or prothionamide (which are not active with *InhA*-gene-mediated resistance but have reasonable CSF penetration; their side-effect profile includes gastrointestinal disturbance, hepatotoxicity and neurotoxicity); and paraminosalicylic acid (which causes rashes and gastrointestinal upset). Linezolid may also be used and has good CSF penetration, while meropenem with co-amoxiclav is occasionally chosen. New drugs developed for XDR-TB include delamanid and bedaquiline (which targets the ATP synthase); their adverse effects include QT prolongation and cardiac arrhythmias. Their co-administration with other agents with a similar side-effect profile (e.g. fluoroquinolones) therefore requires careful risk assessment. Pretomanid is used in combinations with bedaquiline for drug-resistant strains and improves the bactericidal activity of combination therapy which may enable shorter durations. Its side-effects include nerve damage, headaches, gastrointestinal upset, abnormal liver function tests, low glucose and skin rash.

### Clofazimine

Clofazimine is used against *M. leprae* and resistant strains of *M. tuberculosis*. Its mode of action may involve induction of oxidative stress and it is weakly bactericidal. Oral absorption is variable and it is excreted in the bile. Side-effects include gastrointestinal upset, dry eyes and skin, and skin pigmentation, especially in those with pigmented skin.

## Antifungal agents

See [Box 6.25](#).

### Azole antifungals

The azoles (imidazoles and triazoles) inhibit synthesis of ergosterol, a constituent of the fungal cell membrane. Side-effects vary but include gastrointestinal upset, hepatitis and rash. Azoles are inhibitors of cytochrome P450 enzymes, so tend to increase exposure to cytochrome P450-metabolised drugs.

### Imidazoles

Miconazole, econazole, clotrimazole and ketoconazole are relatively toxic and therefore administered topically. Clotrimazole is used extensively to treat superficial fungal infections. Triazoles are used for systemic treatment because they are less toxic.

6.25 Antifungal agents		
Agent	Usual route(s) of administration	Clinically relevant antifungal spectrum
<b>Imidazoles</b>		
Miconazole	} Topical	<i>Candida</i> spp., dermatophytes
Econazole		
Clotrimazole		
Ketoconazole	Topical, oral	<i>Malassezia</i> spp., dermatophytes, agents of eumycetoma
<b>Triazoles</b>		
Fluconazole	Oral, IV	Yeasts ( <i>Candida</i> and <i>Cryptococcus</i> spp.)
Itraconazole	Oral, IV	Yeasts, dermatophytes, dimorphic fungi (p. 342), <i>Aspergillus</i> spp.
Voriconazole	Oral, IV	Yeasts and most filamentous fungi (excluding mucoraceous moulds)
Posaconazole	Oral, IV	Yeasts and many filamentous fungi (including most mucoraceous moulds)
Isavuconazole	Oral, IV	Yeasts and many filamentous fungi (variable activity against mucoraceous moulds)
<b>Echinocandins</b>		
Anidulafungin	} IV only	<i>Candida</i> spp., <i>Aspergillus</i> spp. (no activity against <i>Cryptococcus</i> spp. or mucoraceous moulds)
Caspofungin		
Micafungin		
<b>Polyenes</b>		
Amphotericin B	IV	Yeasts and most dimorphic and filamentous fungi (including mucoraceous moulds)
Nystatin	Topical	
<b>Others</b>		
5-fluorocytosine	Oral, IV	Yeasts
Griseofulvin	Oral	Dermatophytes
Terbinafine	Topical, oral	Dermatophytes

(IV = intravenous)

### Triazoles

Fluconazole is effective against yeasts (*Candida* and *Cryptococcus* spp.) and has a long half-life (approximately 30 hours) and an excellent safety profile. The drug is highly water-soluble and distributes widely to all body sites and tissues, including CSF. Itraconazole is lipophilic and distributes extensively, including to toenails and fingernails. Its CSF penetration is poor. Because oral absorption of itraconazole is erratic, therapeutic drug monitoring is required. Voriconazole is well absorbed orally but variability in levels requires therapeutic drug monitoring. It is used mainly in aspergillosis. Side-effects include photosensitivity, hepatitis and transient retinal toxicity. Posaconazole and isavuconazole are broad-spectrum azoles, with activity against *Candida* spp., *Aspergillus* spp. and some mucoraceous moulds. Isavuconazole is non-inferior to voriconazole in the management of invasive aspergillosis and may be considered as an alternative when voriconazole cannot be used.

### Echinocandins

The echinocandins inhibit  $\beta$ -1,3-glucan synthesis in the fungal cell wall. They have few significant adverse effects. Caspofungin, anidulafungin and micafungin are used to treat systemic candidosis, and caspofungin is also used in aspergillosis.

### Polyenes

Amphotericin B (AmB) deoxycholate causes cell death by binding to ergosterol and damaging the fungal cytoplasmic membrane. Its use in resource-rich countries has been largely supplanted by less toxic agents. Its long half-life enables once-daily administration. CSF penetration is poor.

Adverse effects include immediate anaphylaxis, other infusion-related reactions and nephrotoxicity. Nephrotoxicity may be sufficient to require dialysis and occurs in most patients who are adequately dosed. It may be ameliorated by concomitant infusion of normal saline. Irreversible nephrotoxicity occurs with large cumulative doses of AmB.

Nystatin has a similar spectrum of antifungal activity to AmB. Its toxicity limits it to topical use, e.g. in oral and vaginal candidiasis.

#### Lipid formulations of amphotericin B

Lipid formulations of AmB have been developed to reduce AmB toxicity and have replaced AmB deoxycholate in many regions. They consist of AmB encapsulated in liposomes (liposomal AmB, L-AmB) or complexed with phospholipids (AmB lipid complex, ABLC). The drug becomes active on dissociating from its lipid component. Adverse effects are similar to, but considerably less frequent than, those with AmB deoxycholate, and efficacy is similar. Lipid formulations of AmB are used in invasive fungal disease, as empirical therapy in patients with neutropenic fever and also in visceral leishmaniasis.

### Other antifungal agents

#### Flucytosine

Flucytosine (5-fluorocytosine) has particular activity against yeasts. When it is used as monotherapy, acquired resistance develops rapidly, so it should be given in combination with another antifungal agent. Adverse effects include myelosuppression, gastrointestinal upset and hepatitis.

#### Griseofulvin

Griseofulvin has been largely superseded by terbinafine and itraconazole for treatment of dermatophyte infections, except in children, for whom these agents remain largely unlicensed. It is deposited in keratin precursor cells, which become resistant to fungal invasion.

#### Terbinafine

Terbinafine distributes with high concentration to sebum and skin, with a half-life of more than 1 week. It is used topically for dermatophyte skin infections and orally for onychomycosis. The major adverse reaction is hepatic toxicity (approximately 1:50 000 cases). Terbinafine is not recommended for breastfeeding mothers.

### Antiviral agents

Most viral infections in immunocompetent individuals resolve without intervention. Antiviral therapy is available for a limited number of infections only (Box 6.26).

### Antiretroviral agents

These agents, used predominantly against HIV, are discussed on page 366.

### Anti-herpesvirus agents

#### Aciclovir, valaciclovir, penciclovir and famciclovir

These antivirals are acyclic analogues of guanosine, which inhibit viral DNA polymerase after being phosphorylated by virus-derived thymidine kinase (TK). Aciclovir is poorly absorbed after oral dosing; better levels are achieved intravenously or by use of the prodrug valaciclovir. Famciclovir is the prodrug of penciclovir. Resistance is mediated by viral TK or polymerase mutations.

## 6.26 Antiviral agents

Drug	Route(s) of administration	Indications	Significant side-effects
<b>Antiretroviral therapy</b>			
(ART, p. 366)	Oral	HIV infection (including AIDS)	CNS symptoms, anaemia, lipodystrophy
<b>Anti-herpesvirus agents</b>			
Aciclovir	Topical/oral/IV	Herpes zoster Chickenpox (esp. in immunosuppressed) Herpes simplex infections: encephalitis (IV only), genital tract, oral, ophthalmic	Significant side-effects rare Hepatitis, renal impairment and neurotoxicity reported rarely
Valaciclovir			
Famciclovir	Oral	Herpes zoster, herpes simplex (genital)	As for aciclovir
Penciclovir	Topical	Labial herpes simplex	Local irritation
Ganciclovir	IV	Treatment and prevention of CMV infection in immunosuppressed	Gastrointestinal symptoms, liver dysfunction, neurotoxicity, myelosuppression, renal impairment, fever, rash, phlebitis at infusion sites Potential teratogenicity
Valganciclovir	Oral	Treatment and prevention of CMV infection in immunosuppressed	As for ganciclovir but neutropenia is predominant
Cidofovir	IV/topical	HIV-associated CMV infections and occasionally other viruses (see text)	Renal impairment, neutropenia
Foscarnet	IV	CMV and aciclovir-resistant HSV and VZV infections in immunosuppressed	Gastrointestinal symptoms, renal impairment, electrolyte disturbances, genital ulceration, neurotoxicity
<b>Anti-influenza agents</b>			
Zanamivir	Inhalation	Influenza A and B	Allergic reactions (very rare)
Oseltamivir	Oral	Influenza A and B	Gastrointestinal side-effects, rash, hepatitis (very rare)
Peramivir	IV, IM		
Amantadine, rimantadine	Oral	Influenza A (but see text)	CNS symptoms, nausea
<b>Agents used in other virus infections*</b>			
Ribavirin	Oral/IV/ inhalation	Lassa fever (IV) RSV infection in infants (inhalation)	Haemolytic anaemia, cough, dyspnoea, bronchospasm and ocular irritation (when given by inhalation)
Remdesivir	IV	COVID-19 (experimental, not recommended for clinical use at the time of writing)	Significant side-effects rare
*Antiviral agents used in viral hepatitis are discussed on pages 884–890. (AIDS = acquired immunodeficiency syndrome; CMV = cytomegalovirus; CNS = central nervous system; HIV = human immunodeficiency virus; HSV = herpes simplex virus; IM = intramuscular; IV = intravenous; RSV = respiratory syncytial virus; VZV = varicella zoster virus)			

6

**Ganciclovir**

Chemical modification of the aciclovir molecule allows preferential phosphorylation by protein kinases of cytomegalovirus (CMV) and other  $\beta$ -herpesviruses (e.g. human herpesvirus (HHV) 6/7) and hence greater inhibition of the DNA polymerase, but at the expense of increased toxicity. Ganciclovir is administered intravenously or as a prodrug (valganciclovir) orally.

**Cidofovir**

Cidofovir inhibits viral DNA polymerases with potent activity against CMV, including most ganciclovir-resistant CMV. It also has activity against aciclovir-resistant herpes simplex virus (HSV) and varicella zoster virus (VZV), HHV6 and occasionally adenovirus, poxvirus, papillomavirus or polyoma virus, and may be used to treat these infections in immunocompromised hosts.

**Foscarnet**

This analogue of inorganic pyrophosphate acts as a non-competitive inhibitor of HSV, VZV, HHV6/7 or CMV DNA polymerase. It does not require significant intracellular phosphorylation and so may be effective when HSV or CMV resistance is due to altered drug phosphorylation. It has variable CSF penetration.

**Letermovir**

Letermovir is a CMV DNA terminase inhibitor that plays a role in cleavage of viral DNA for packaging into mature virions. It is available in oral and

intravenous formulations. It is well tolerated and is approved for prophylaxis of CMV in allogeneic haematopoietic stem cell transplant recipients. Gastrointestinal disturbance and drug–drug interactions occur and resistance may develop.

**Anti-influenza agents****Zanamivir and oseltamivir**

These agents inhibit influenza A and B neuraminidase, which is required for release of virus from infected cells (see Fig. 6.2). They are used in the treatment and prophylaxis of influenza. Administration within 48 hours of disease onset reduces the duration of symptoms by approximately 1–1½ days. In the UK, their use is limited mainly to adults with chronic respiratory or renal disease, significant cardiovascular disease, immunosuppression or diabetes mellitus, during known outbreaks. Peramivir has been developed as a distinct chemical structure, which means that it retains activity against some oseltamivir- and zanamivir-resistant strains. It has poor oral bioavailability and has been developed as an intravenous or intramuscular formulation for treatment of severe cases of influenza, e.g. in intensive care units. It is now approved for use in adults in a number of countries. An intravenous formulation of zanamivir is also in development for critically ill patients. Laninamivir is approved as an intranasal formulation in Japan.

### Other anti-influenza agents

Amantidine and rimantadine inhibit viral M2 protein ion channel function, which is required for uncoating (see Fig. 6.2). Resistance is widespread, and these are only used to treat oseltamivir-resistant influenza A in patients unable to take zanamivir (e.g. ventilated patients) and when the strain is susceptible to these agents. Baloxavir marboxil inhibits a component of viral RNA synthesis. It is licensed for uncomplicated influenza but is likely to be reserved for neuraminidase-resistant strains. Faviparvir is an oral or intravenous RNA-dependent RNA polymerase that may also play a role against resistant strains of influenza but also other RNA viruses and has been studied against SARS-CoV-2.

### Other agents used to treat viruses

Antiviral agents used to treat hepatitis B and C virus are discussed on pages 886 and 889, and those used against HIV-1 are described on page 366.

#### Remdesivir

Remdesivir is an intravenous RNA-dependent RNA polymerase inhibitor that has a broad antiviral spectrum *in vitro* and has decreased the time to recovery following SARS-CoV-2 infection. So far it has not demonstrated efficacy against other viruses clinically. Initial studies have not shown significant effects on SARS-CoV-2 viral replication, suggesting it may need to be used early in the course of infection before peak viral replication. The main side-effects include abnormal liver function tests and infusion reactions.

#### Ribavirin

Ribavirin is a guanosine analogue that inhibits nucleic acid synthesis in a variety of viruses. It is used in particular in the treatment of hepatitis C virus but also against certain viral haemorrhagic fevers, e.g. Lassa fever, although it has not been useful against Ebola virus.

## Antiparasitic agents

### Antimalarial agents

#### Artemisinin (qinghaosu) derivatives

Artemisinin originates from a herb (sweet wormwood, *Artemisia annua*), which was used in Chinese medicine to treat fever. Its derivatives, artemether and artesunate, were developed for use in malaria in the 1970s. Their mechanism of action is unknown. They are used in the treatment, but not prophylaxis, of malaria, usually in combination with other antimalarials, and are effective against strains of *Plasmodium* spp. that are resistant to other antimalarials. Artemether is lipid-soluble and may be administered via the intramuscular and oral routes. Artesunate is water-soluble and is administered intravenously or orally. Serious adverse effects are uncommon. Current advice for malaria in pregnancy is that the artemisinin derivatives should be used to treat uncomplicated *falciparum* malaria in the second and third trimesters, but should not be prescribed in the first trimester until more information becomes available.

#### Atovaquone

Atovaquone inhibits mitochondrial function. It is an oral agent, used for treatment and prophylaxis of malaria, in combination with proguanil (see below), without which it is ineffective. It is also employed in the treatment of mild cases of *Pneumocystis jirovecii* pneumonia, or as prophylaxis, where there is intolerance to co-trimoxazole. Significant adverse effects are uncommon.

#### Folate synthesis inhibitors (proguanil, pyrimethamine-sulfadoxine)

Proguanil inhibits dihydrofolate reductase and is used for malaria prophylaxis. Pyrimethamine-sulfadoxine may be used in the treatment of malaria.

#### Quinoline-containing compounds

Chloroquine and quinine are believed to act by intraparasitic inhibition of haem polymerisation, resulting in toxic build-up of intracellular haem.

The mechanisms of action of other agents in this group (quinidine, amodiaquine, mefloquine, primaquine, etc.) may differ. They are employed in the treatment and prophylaxis of malaria. Primaquine is used for radical cure of malaria due to *Plasmodium vivax* and *P. ovale* (destruction of liver hypnozoites). Chloroquine may also be given for extraintestinal amoebiasis.

Chloroquine can cause significant pruritus. If used in long-term, high-dose regimens, it causes an irreversible retinopathy. Overdosage leads to life-threatening cardiotoxicity. The side-effect profile of mefloquine includes neuropsychiatric effects ranging from mood change, nightmares and agitation to hallucinations and psychosis. Quinine may cause hypoglycaemia and cardiotoxicity, especially when administered parenterally. Primaquine causes haemolysis in people with glucose-6-phosphate dehydrogenase deficiency, which should be excluded before therapy. Chloroquine is considered safe in pregnancy but mefloquine should be avoided in the first trimester.

Chloroquine (and its metabolite hydroxychloroquine) exhibits *in vitro* activity against the virus SARS-CoV-2 but has not demonstrated clinical efficacy.

#### Lumefantrine

Lumefantrine is used in combination with artemether to treat uncomplicated *falciparum* malaria, including chloroquine-resistant strains. Its mechanism of action is unknown. Significant adverse effects are uncommon.

### Drugs used in trypanosomiasis

The antiparasitic agents used to treat human African trypanosomiasis (HAT) and American trypanosomiasis (Chagas' disease) (benznidazole, eflornithine, fexinidazole, melarsoprol, nifurtimox, pentamidine and suramin) are discussed in detail on pages 324 and 325.

In addition to its use in HAT, pentamidine is used in leishmaniasis (p. 327) and in severe *Pneumocystis jirovecii* pneumonia, if co-trimoxazole cannot be tolerated or is ineffective. It is administered via intravenous or intramuscular routes. It is a relatively toxic drug, commonly causing rash, renal impairment, profound hypotension (especially on rapid infusion), electrolyte disturbances, blood dyscrasias and hypoglycaemia.

### Other antiprotozoal agents

#### Pentavalent antimonials

Sodium stibogluconate and meglumine antimoniate inhibit protozoal glycolysis by phosphofructokinase inhibition. They are used parenterally (intravenous or intramuscular) to treat leishmaniasis. Adverse effects include arthralgia, myalgias, raised hepatic transaminases, pancreatitis and electrocardiogram changes. Severe cardiotoxicity leading to death is not uncommon.

#### Diloxanide furoate

This oral agent is used to eliminate luminal cysts following treatment of intestinal amoebiasis, or in asymptomatic cyst excretors. The drug is absorbed slowly (enabling luminal persistence) and has no effect in hepatic amoebiasis. It is a relatively non-toxic drug, the most significant adverse effect being flatulence.

#### Iodoquinol (di-iodohydroxyquinoline)

Iodoquinol is a quinoline derivative with activity against *Entamoeba histolytica* cysts and trophozoites. It is used orally to treat asymptomatic cyst excretors or, in association with another amoebicide (e.g. metronidazole), to treat extraintestinal amoebiasis. Long-term use of this drug is not recommended, as neurological adverse effects include optic neuritis and peripheral neuropathy.

#### Nitazoxanide

Nitazoxanide is an inhibitor of pyruvate-ferredoxin oxidoreductase-dependent anaerobic energy metabolism in protozoa. It is a broad-spectrum agent, active against various nematodes, tapeworms, flukes and

intestinal protozoa. Nitazoxanide also has activity against some anaerobic bacteria and viruses. It is administered orally in giardiasis and cryptosporidiosis. Adverse effects are usually mild and involve the gastrointestinal tract (e.g. nausea, diarrhoea and abdominal pain).

### **Paromomycin**

Paromomycin is an aminoglycoside that is used to treat visceral leishmaniasis and intestinal amoebiasis. It is not significantly absorbed when administered orally, and is therefore given orally for intestinal amoebiasis and by intramuscular injection for leishmaniasis. It showed early promise in the treatment of HIV-associated cryptosporidiosis but subsequent trials have demonstrated that this effect is marginal at best.

## **Drugs used against helminths**

### **Benzimidazoles (albendazole, mebendazole)**

These agents act by inhibiting both helminth glucose uptake, causing depletion of glycogen stores, and fumarate reductase. Albendazole is used for hookworm, ascariasis, threadworm, *Strongyloides* infection, trichinellosis, *Taenia solium* (cysticercosis) and hydatid disease. Mebendazole is used for hookworm, ascariasis, threadworm and whipworm. The drugs are administered orally. Absorption is relatively poor but is increased by a fatty meal. Significant adverse effects are uncommon.

### **Bithionol**

Bithionol is used to treat fluke infections with *Fasciola hepatica*. It is well absorbed orally. Adverse effects are mild (e.g. nausea, vomiting, diarrhoea, rashes) but relatively common (approximately 30%).

### **Diethylcarbamazine**

Diethylcarbamazine (DEC) is an oral agent used to treat filariasis and loiasis. Treatment of filariasis is often followed by fever, headache, nausea, vomiting, arthralgia and prostration. This is caused by the host response to dying microfilariae, rather than the drug, and may be reduced by pre-treatment with glucocorticoids.

### **Ivermectin**

Ivermectin binds to helminth nerve and muscle cell ion channels, causing increased membrane permeability. It is an oral agent, used in *Strongyloides* infection, filariasis and onchocerciasis. Significant side-effects are uncommon.

### **Niclosamide**

Niclosamide inhibits oxidative phosphorylation, causing paralysis of helminths. It is an oral agent, used in *Taenia saginata* and intestinal *T. solium* infection. Systemic absorption is minimal and it has few significant side-effects.

### **Piperazine**

Piperazine inhibits neurotransmitter function, causing helminth muscle paralysis. It is an oral agent, used in ascariasis and threadworm (*Enterobius vermicularis*) infection. Significant adverse effects are uncommon but include neuropsychological reactions such as vertigo, delirium and convulsions.

### **Praziquantel**

Praziquantel increases membrane permeability to  $Ca^{2+}$ , causing violent contraction of worm muscle. It is the drug of choice for schistosomiasis and is also used in *T. saginata*, *T. solium* (cysticercosis) and fluke infections (*Clonorchis*, *Paragonimus*) and in echinococcosis. It is administered orally and is well absorbed. Adverse effects are usually mild and transient, and include nausea and abdominal pain.

### **Pyrantel pamoate**

This agent causes spastic paralysis of helminth muscle through a suxamethonium-like action. It is used orally in ascariasis and threadworm infection. Systemic absorption is poor and adverse effects are uncommon.

### **Thiabendazole**

Thiabendazole inhibits fumarate reductase, which is required for energy production in helminths. It is used orally in *Strongyloides* infection and topically to treat cutaneous larva migrans. Significant adverse effects are uncommon.

## Multiple Choice Questions

- 6.1. A 19-year-old student who had not received any childhood vaccines through parental choice attends a music festival. Nine days later she develops an illness consisting of conjunctivitis and malaise with some intraoral lesions, followed by a generalised maculopapular rash. With respect to the most likely causative organism, which of the following statements is false?
- A. The basic reproduction number ( $R_0$ ) for this pathogen is one of the highest encountered for an infectious disease
  - B.  $R_0$  gives an estimate of how many infections are likely to arise from an infected individual and is dependent on vaccine uptake and previous infections
  - C.  $R_0$  for this infection is higher than that for SARS-CoV-2 and Ebola
  - D. Since  $R_0$  for this infection is high the proportion of the population who need to be immunised to prevent spread of infection is high
  - E.  $R_0$  gives an estimate of how many infections are likely to arise from an infected individual taking into account vaccine uptake in the population

Answer: B.

The case describes a measles infection.  $R_0$  is an estimate of the number of cases that can be expected to be acquired from a single primary case when all individuals in the population are susceptible to infection, and is high for measles (usually cited as 12–18).  $R_0$  is dependent on the inherent transmissibility of the organism and assumes susceptibility of the population.  $R_0$  is affected by the social habits and interactions of a population at the time it is calculated, and therefore the  $R_0$  for a disease transmitted by close contact will be higher if calculated in a densely populated area than a sparsely populated area. Because measles has a high  $R_0$  the number of people in the population who need to be vaccinated to control measles is high.  $R_0$  gives a more accurate assessment of the number of infections that can be expected to arise within a population than  $R_0$  because it takes into account the number of susceptible individuals within the population (i.e. vaccinated individuals and those who have acquired immunity through natural infection) as well as changes in behaviour (e.g. the introduction of social distancing, use of personal protective equipment etc.).  $R_0$  therefore varies with time and population behaviour.

- 6.2. A 23-year-old woman with cystic fibrosis and a history of multiple infectious exacerbations is admitted to hospital with increasing breathlessness. A chest X-ray reveals patchy infiltrates throughout the right lower lung on a background of bronchial dilatation in both lungs. Sputum culture yields profuse growth of an oxidase-positive Gram-negative bacillus. The patient has a history of rash with piperacillin-tazobactam but has tolerated cephalosporins without previous problems. Which of the following would be a suitable agent to treat the most likely causative organism?
- A. Cefaclor
  - B. Cefazolin
  - C. Ceftriaxone
  - D. Ceftazidime
  - E. Cephalixin

Answer: D.

The patient has a history of cystic fibrosis with multiple infectious exacerbations. Although an oxidase-positive Gram-negative bacillus could describe several organisms, the most likely one in a setting of cystic fibrosis with multiple infective exacerbations is *P. aeruginosa*. As the

patient has tolerated cephalosporins previously with no problems, it is reasonable to treat her with an anti-pseudomonal cephalosporin despite her history of rash with another beta-lactam antibiotic (piperacillin-tazobactam). Ceftazidime is the only anti-pseudomonal cephalosporin on this list. The only other third-generation cephalosporin that has good Gram-negative coverage on the list is ceftriaxone, but it lacks activity against *P. aeruginosa*.

- 6.3. A 58-year-old man with diabetes mellitus is hospitalised with an acute myocardial infarction. He develops cardiac failure and acute kidney injury (AKI) and spends a period of time in the cardiac intensive care unit. He subsequently develops a fever and his blood cultures are positive for a yeast, which is identified as *Candida krusei*. An antifungal agent is selected on the basis of likely susceptibility and patient comorbidities. The mechanism of action of this antifungal is:
- A. Accumulation of toxic 14 $\alpha$ -methylated sterols
  - B. DNA topoisomerase inhibition
  - C. Ergosterol synthesis inhibition in the cell membrane
  - D. Impairment of DNA synthesis due to inhibition of thymidylate synthase
  - E. Inhibition of  $\beta$ -1,3-glucan synthesis in the cell wall

Answer: E.

The candidaemia is likely to be related to a central venous catheter infection and *Candida krusei* is resistant to antifungal azoles. The best initial therapy is therefore an echinocandin such as caspofungin, which acts by inhibiting fungal  $\beta$ -1,3-glucan synthase. It would not be appropriate to treat this patient with an amphotericin B preparation because of his AKI and the potential for nephrotoxicity. Antifungal azoles act by inhibiting ergosterol synthesis resulting in toxic accumulation of 14 $\alpha$ -methylated sterols. Flucytosine (5-fluorocytosine) inhibits DNA synthesis by its actions on thymidylate synthase. Inhibition of bacterial DNA topoisomerases is the mechanism of action of fluoroquinolones, but not of any antifungals.

- 6.4. A 26-year-old man who grew up on a farm in rural Argentina is investigated for chronic abdominal pain and weight loss. He is found on investigation to have infection with *Taenia saginata* and treatment is recommended. Guidelines suggest you should prescribe praziquantel but your pharmacy is not able to obtain any supplies of this drug. What would be a suitable alternative agent to use to treat this infection?
- A. Bithionol
  - B. Diethylcarbamazine
  - C. Niclosamide
  - D. Piperazine
  - E. Thiabendazole

Answer: C.

Infections with intestinal tapeworms such as *T. saginata* are often asymptomatic but can occasionally give rise to symptoms, as in this case. The preferred treatment for *Taenia* infections is praziquantel but niclosamide or nitazoxanide are alternatives. The other agents listed are used for other helminth infections.

Immune checkpoint inhibitor-induced colitis: A comprehensive review. *World J Clin Cases* 2019; 7(4):405–418.

Cancer represents a significant global health, social and economic burden. In 2018 there were 17 million new cases of cancer worldwide and 9.6 million cancer deaths, making it the second leading cause of death. By 2030, it is projected that there will be 26 million new cancer cases and 17 million cancer deaths per year. The developing world is disproportionately affected by cancer and in 2018 approximately 70% of cancer deaths occurred in low- and middle-income countries. These deaths happen in countries with limited or no access to investigations or treatment and with low per capita expenditure on health care.

The most common solid organ malignancies arise in the lung, breast and gastrointestinal tract (Fig. 7.1), but the most common form worldwide is skin cancer. Cigarette smoking accounts for more than 20% of all global cancer deaths, 80% of lung cancer cases in men and 50% of lung cancer cases in women worldwide, which could be prevented by smoking cessation. Diet and alcohol contribute to a further 30% of cancers, including those of the stomach, colon, oesophagus, breast and liver. Lifestyle modification could reduce these if steps were taken to avoid animal fat and red meat, reduce alcohol, increase fibre, fresh fruit and vegetable intake, avoid obesity and increase physical activity. Infections account for a further 15% of cancers (25% of cancers in low- and middle-income countries), including those of the cervix, stomach, liver, nasopharynx, anus and bladder, and some of these could be prevented by infection control and vaccination.

## The 10 hallmarks of cancer

The formation and growth of cancer is a multistep process, during which normal cells are transformed into malignant cells. Ten key characteristics that underlie these steps, collectively referred to as the 'Hallmarks of Cancer', have been described.

**Fig. 7.1** The most commonly diagnosed cancers in the UK. (CNS = central nervous system; NHL = non-Hodgkin lymphoma) Statistics from Cancer Research UK website (<http://info.cancerresearchuk.org>).

## 1. Genome instability and mutation

Random genomic aberrations occur continuously throughout all cells of the body. This may include somatic point mutations, insertions, deletions and chromosome structural changes (i.e. copy number changes, chromosomal translocations). Epigenomic aberrations, such as DNA methylation and histone modification, may also occur. Rarely, aberrations will confer a selective survival advantage on single cells, 'driving' overgrowth and dominance in local tissue environments. Multistep carcinogenesis results from successive clonal expansions of pre-malignant cells, each expansion being triggered by acquisition of a random driver aberration.

Under normal circumstances, genome maintenance systems and DNA repair mechanisms are so effective that almost all spontaneous genomic aberrations are repaired, or damaged cells are forced into senescence or apoptosis. In cancer cells, though, the accumulation of mutations can be accelerated by compromising these maintenance mechanisms. In turn, this leads to the accumulation of driver genomic aberrations which lead to cancer growth and progression. Genomic sequencing technology demonstrates that the pattern of aberrations vary dramatically between cancer types. However, defects in genome maintenance mechanisms leading to genome instability are common findings across all cancers. This enabling characteristic may lead to the acquisition of other hallmarks.

## 2. Resisting cell death

There are three principal mechanisms through which cell death occurs in healthy tissues: apoptosis, autophagy and necrosis.

### Apoptosis

This is programmed cell death. It is frequently found at markedly reduced rates in cancers, particularly those of high grade or those resistant to treatment. The cellular apoptotic system has regulatory elements that sense intrinsic and extrinsic pro-apoptotic signals. This initiates a cascade of proteolysis and cell disassembly with nuclear fragmentation, chromosomal condensation and shrinking of the cell with loss of inter-cellular contact, followed by cellular fragmentation and the formation of apoptotic bodies that are phagocytosed by neighbouring cells. The most important regulator of apoptosis is the *TP53* tumour suppressor gene, often described as the 'guardian of the genome' as it is able to induce apoptosis in response to sufficient levels of genomic damage. The largest initiator of apoptosis via *TP53* is cellular injury, particularly that due to DNA damage from cytotoxic chemotherapy, oxidative damage and ultraviolet (UV) radiation. Disruption of p53 protein function as a result of mutations in the *TP53* gene are found in over half of cancers.

### Autophagy

This is a catabolic process during which cellular constituents are degraded by lysosomal machinery within the cell. It is an important physiological mechanism; it usually occurs at low levels in cells but can be induced in response to environmental stresses, particularly radiotherapy and cytotoxic chemotherapy, which induce elevated levels of autophagy that are cytoprotective for malignant cells, thus impeding rather than perpetuating the killing actions of these stress situations. Severely stressed cancer cells have been shown to shrink via autophagy to a state of reversible dormancy.

### Necrosis

This is the premature death of cells and is characterised by the release of cellular contents into the local tissue microenvironment, in marked contrast to apoptosis, where cells are disassembled in a step-by-step fashion and the resulting cellular fragments are phagocytosed. Necrotic cell

death results in the recruitment of inflammatory immune cells, promotion of angiogenesis and release of stimulatory factors that increase cellular proliferation and tissue invasion, thereby enhancing rather than inhibiting carcinogenesis.

### 3. Sustaining proliferative signalling

The 'cell cycle' is tightly controlled at different stages. Normal cells grow and divide in response to external signals, typically growth factors. These are able to bind to cell surface-bound receptors that activate an intracellular tyrosine kinase-mediated signalling cascade, ultimately leading to changes in gene expression that promote cellular proliferation and growth.

#### The cell cycle

The cell cycle is composed of four ordered, strictly regulated phases referred to as  $G_1$  (gap 1), S (DNA synthesis),  $G_2$  (gap 2) and M (mitosis) (Fig. 7.2). Normal cells grown in culture will stop proliferating and enter a quiescent state called  $G_0$  once they become confluent or are deprived of serum or growth factors. The first gap phase ( $G_1$ ) prior to the initiation of DNA synthesis represents the period of commitment that separates M and S phases as cells prepare for DNA duplication. Cells in  $G_0$  and  $G_1$  are receptive to growth signals, but once they have passed a restriction point, they are committed to enter DNA synthesis (S phase). Cells demonstrate arrest at different points in  $G_1$  in response to different inhibitory growth signals. Mitogenic signals promote progression through  $G_1$  to S phase, utilising phosphorylation of the retinoblastoma gene product (pRB, p. 40). Following DNA synthesis, there is a second gap phase ( $G_2$ ) prior to mitosis (M), allowing cells to repair errors that have occurred during DNA replication and thus preventing propagation of these errors to daughter cells. Although the duration of individual phases may vary, depending on cell and tissue type, most adult cells are in a  $G_0$  state at any one time.

#### Stimulation of the cell cycle

Many cancer cells produce growth factors, which drive their own proliferation by a positive feedback mechanism known as autocrine stimulation.

Examples include transforming growth factor- $\alpha$  (TGF- $\alpha$ ) and platelet-derived growth factor (PDGF). Other cancer cells express growth factor receptors at increased levels due to gene amplification or express abnormal receptors that are permanently activated. This results in abnormal cell growth in response to physiological growth factor stimulation or even in the absence of growth factor stimulation (ligand-independent signalling). The epidermal growth factor receptor (EGFR) is often over-expressed in lung and gastrointestinal tumours and the human epidermal growth factor receptor 2 (HER2)/neu receptor is frequently over-expressed in breast cancer. Both receptors activate the Ras-Raf-mitogen activated protein (MAP) kinase pathway, causing cell proliferation.

### 4. Evading growth suppressors

The cell cycle is orchestrated by a number of molecular mechanisms, most importantly by cyclins and cyclin-dependent kinases (CDKs). Cyclins bind to CDKs and are regulated by both activating and inactivating phosphorylation, with two main checkpoints at  $G_1/S$  and  $G_2/M$  transition. The genes that inhibit progression play an important part in tumour prevention and are referred to as tumour suppressor genes (e.g. *TP53*, *TP21*, *TP16* genes). The products of these genes deactivate the cyclin-CDK complexes and are thus able to halt the cell cycle. The complexity of cell cycle control is susceptible to dysregulation, and mutations within inhibitory proteins are common in cancer.

### 5. Enabling replicative immortality

Normal cells have a limited number of divisions before they are unable to divide further (senescence) or before they die (crisis). These limits are controlled by telomeric DNA sequences, which protect and stabilise chromosomal ends. During replication, telomeres shorten progressively as small fragments of telomeric DNA are lost with successive cycles of replication. This shortening process represents a mitotic clock and eventually prevents the cell from dividing further. Telomerase, a specialised polymerase enzyme, adds nucleotides to telomeres, allowing continued cell division and thus preventing premature arrest of cellular replication. The telomerase enzyme is almost absent in normal cells but is expressed at significant levels in the majority of human cancers.

Fig. 7.2 The cell cycle and sites of action of chemotherapeutic agents. (CDK = cyclin-dependent kinase; RB = retinoblastoma gene)

**Fig. 7.3 Oncogenesis.** The multistep origin of cancer, showing events implicated in cancer initiation, progression, invasion and metastasis.

## 6. Inducing angiogenesis

All cells and body tissues require sustenance in the form of nutrients and oxygen, as well as an ability to evacuate metabolic waste products and carbon dioxide. Tumours require a functional vascular network to ensure continued growth and are unable to grow beyond  $1\text{ mm}^3$  without stimulating the development of a vascular supply through angiogenesis (Figs. 7.3 and 7.4).

Angiogenesis is dependent on the production of angiogenic growth factors, of which vascular endothelial growth factor (VEGF) and platelet-derived growth factor (PDGF) are the best characterised. During tumour progression, an angiogenic switch is activated and remains on, causing normally quiescent vasculature to develop new vessels continually to help sustain expanding tumour growth. Angiogenesis is governed by a balance of pro-angiogenic stimuli and angiogenesis inhibitors, such as thrombospondin (TSP)-1, which binds to transmembrane receptors on endothelial cells and evokes suppressive signals. A number of cells can contribute to the maintenance of a functional tumour vasculature and therefore sustain angiogenesis. These include pericytes and a variety of bone marrow-derived cells such as macrophages, neutrophils, mast cells and myeloid progenitors.

## 7. Activating invasion and metastasis

The ability to invade neighbouring tissue determines whether a tumour is benign or malignant. Clinically, the presence of metastases often determines whether a cancer can be cured. The invasion-metastatic cascade is a complex multistep process. The initiation of this process is enabled by epithelial-mesenchymal transition (EMT). Cancer cells in a tumour lose normal cell-cell adhesion through the down-regulation or, occasionally, mutational inactivation of E-cadherin, a calcium-dependent cell-cell adhesion glycoprotein. After breaking through the basement membrane, cancer cells enter the blood stream (intravasation). These circulating tumour cells (CTCs) then exit the blood stream into distant tissues (extravasation) to form small nodules of cancer cells (micrometastases).

**Fig. 7.4 Angiogenesis, invasion and metastasis.** **A** For any cancer to grow beyond  $1\text{ mm}^3$ , it must evoke a blood supply. **B** New vessel formation results from the release of angiogenic factors by the tumour cells and loss of inhibition of the endothelial cells. **C** The loss of cellular adhesion and disruption of the extracellular matrix allow cells to extravasate into the blood stream and metastasise to distant sites. (VEGF = vascular endothelial growth factor)

Following mesenchymal-epithelial transition these micrometastatic lesions develop into macroscopic tumours (colonisation) (see Fig. 7.3).

Cross-talk between cancer cells and cells of the surrounding stromal tissue is involved in the acquired capability for invasive growth and metastasis. Mesenchymal stem cells in tumour stroma have been found

to secrete CCL5, a protein chemokine that helps recruit leucocytes into inflammatory sites. With the help of particular T-cell-derived cytokines (interleukin (IL)-2 and interferon-gamma (IFN- $\gamma$ )), CCL5 induces proliferation and activation of natural killer cells and then acts reciprocally on cancer cells to stimulate invasive behaviour. Macrophages at the tumour periphery can foster local invasion by supplying matrix-degrading enzymes such as metalloproteinases and cysteine cathepsin proteases.

## 8. Deregulating cellular energetics

Under aerobic conditions, oxidative phosphorylation functions as the main metabolic pathway for energy production; cells process glucose, first to pyruvate via glycolysis and thereafter to carbon dioxide in the mitochondria. While under anaerobic conditions, glycolysis is favoured to produce adenosine triphosphate (ATP). Cancer cells can reprogram their glucose metabolism to limit energy production to glycolysis, even in the presence of oxygen. This has been termed 'aerobic glycolysis'. Up-regulation of glucose transporters, such as GLUT1, is the main mechanism through which aerobic glycolysis is achieved.

This reprogramming of energy metabolism appears paradoxical, as overall energy production from glycolysis is significantly lower (18-fold) than that from oxidative phosphorylation. One explanation may be that the increased production of glycolytic intermediates can be fed into various biosynthetic pathways, including those that generate the nucleosides and amino acids, necessary for the production of new cells.

## 9. Tumour-promoting inflammation

Almost all tumours show infiltration with immune cells on pathological investigation and historically this finding was thought to represent an attempt of the immune system to eradicate the cancer. It is now clear that tumour-associated inflammatory responses contribute to several hallmark capabilities and promote tumour formation and cancer progression. Immune cells may promote invasive behaviour, and bioactive molecules such as cytokines, growth factors and pro-angiogenic factors may be released into the tumour microenvironment. In particular, the release of reactive oxygen species, which are actively mutagenic, will accelerate the genetic evolution of surrounding cancer cells, enhancing growth and contributing to cancer progression.

## 10. Evading immune destruction

Cancer cells continuously shed antigens into the circulatory system, prompting an immune response that includes cytotoxic T-cell, natural killer cell and macrophage production. The immune system is thought to provide continuous surveillance, with resultant elimination of cells that undergo malignant transformation. However, if not all cancer cells are eliminated there may be a period of equilibrium where tumour growth is controlled by the immune system and cancer cells may enter a dormant state, sometimes for many years. Alternatively, cancer cells may escape immune control and grow into clinically apparent tumours. Several factors may contribute to immune escape, including reduced immune recognition, increased resistance or survival and the development of an immunosuppressive tumour microenvironment.

Immune checkpoints are increasingly recognised as key factors in the immune escape of tumours. These pathways are crucial for regulating the immune response to normal cells by down-regulating the immune system and promoting self-tolerance by suppressing T-cell immune activity. However, some cancers co-opt these protective mechanisms by stimulating immune checkpoint molecular targets such as the programmed cell death ligand (PD-L1), a protein that helps stop immune cells from attacking other cells in the body (see Fig. 7.12).

## Environmental and genetic determinants of cancer

The majority of cancers do not have a single cause but rather are the result of a complex interaction between genetic factors and exposure

to environmental carcinogens. These are often tumour type-specific but some general principles do apply.

### Environmental factors

Environmental triggers for cancer have mainly been identified through epidemiological studies that examine patterns of distribution of cancers in patients in whom parameters such as age, sex, presence of other illnesses, social class, geography and diet differ. Sometimes, these give strong pointers to the molecular or cellular causes of the disease, such as the association between aflatoxin production within contaminated food supplies and hepatocellular carcinomas. For most solid cancers, however, there is evidence of a multifactorial pathogenesis, even when there is a principal environmental cause (Box 7.1).

Smoking is now established beyond all doubt as a major cause of lung cancer, but there are additional predisposing factors since not all smokers develop cancer. Similarly, most carcinomas of the cervix are related to infection with human papillomavirus (HPV subtypes 16 and 18). For carcinomas of the bowel and breast, there is strong evidence of an environmental component. For example, the risk of breast cancer in women of Far Eastern origin remains relatively low when they first migrate to a country with a Western lifestyle, but rises in subsequent generations to approach that of the resident population of the host country. The precise environmental factors that cause this change are unclear but may include diet (higher intake of saturated fat and/or dairy products), reproductive patterns (later onset of first pregnancy) and lifestyle (increased use of artificial light and shift in diurnal rhythm).

### Genetic factors

A number of inherited cancer syndromes are recognised and account for 5%–10% of all cancers (Box 7.2). Their molecular basis is discussed in Chapter 3, but in general they result from inherited mutations in driver genes that regulate cell growth, cell death and apoptosis. Although carriers of these gene mutations have a greatly elevated risk of cancer, none has 100% penetrance and additional modulating factors, both genetic and environmental, are likely to be operative. Exploration of a possible genetic contribution is a key part of cancer management. It may inform anti-cancer therapy decisions in people with cancer. Patients and their family members may also benefit from screening investigations to detect cancer early, or preventative treatments such as prophylactic mastectomy in women who carry a *BRCA1* or *BRCA2* mutation.

## Investigations

When a patient is suspected of having cancer, a full history should be taken. Attention should be paid to potential risk factors such as smoking and occupational exposures, any family history of cancer and elucidating potential complications of the disease. A thorough clinical examination is essential to identify both the primary cancer site and possible sites of metastases, and to discover any other conditions that may have a bearing on the management plan.

In order to plan the most appropriate investigations and management, information is needed on:

- the extent of disease
- the type of cancer
- the patient's fitness.

### Determining the extent of disease (staging)

The extent of disease, such as how large a tumour is and if it has spread, is determined by the process of staging. It entails clinical examination, imaging (e.g. CT, MRI, PET), specialised investigations (e.g. colonoscopy, endoscopy, laparoscopy, mediastinoscopy) and, in some cases, surgery. The outcome is recorded using a standard staging classification that

7.1 Environmental factors that predispose to cancer		
Environmental aetiology	Processes	Diseases
<b>Occupational exposure</b> (see 'Radiation' below)	Dye and rubber manufacturing (aromatic amines) Asbestos mining, construction work, shipbuilding (asbestos) Vinyl chloride (PVC) manufacturing Petroleum industry (benzene)	Bladder cancer Lung cancer and mesothelioma Liver angiosarcoma Acute leukaemia
<b>Chemicals</b>	Cytotoxic chemotherapy (e.g. melphalan, cyclophosphamide)	Acute myeloid leukaemia
<b>Cigarette smoking</b>	Exposure to carcinogens from inhaled smoke	Lung, throat, oesophagus and bladder cancer
<b>Viral infection</b>	Epstein–Barr virus Human papillomavirus Hepatitis B and C viruses	Burkitt lymphoma and nasopharyngeal cancer Cervical cancer, anal cancer, oropharyngeal cancer Hepatocellular carcinoma
<b>Bacterial infection</b>	<i>Helicobacter pylori</i>	Gastric MALT lymphomas, gastric cancer
<b>Parasitic infection</b>	Liver fluke ( <i>Opisthorchis sinensis</i> ) Schistosoma haematobium	Cholangiocarcinoma Squamous cell bladder cancer
<b>Dietary factors</b>	Low-roughage/high-fat content diet High nitrosamine intake Aflatoxin from contamination of <i>Aspergillus flavus</i>	Colonic cancer Gastric cancer Hepatocellular cancer
<b>Obesity</b>	Reduced physical activity, increased insulin Increased oestrogen	Colon cancer Breast and endometrial cancer
<b>Radiation</b>	UV exposure  Nuclear fallout following explosion (e.g. Hiroshima, Chernobyl)  Diagnostic exposure (e.g. CT) Occupational exposure (e.g. beryllium and strontium mining) Therapeutic radiotherapy	Basal cell carcinoma Melanoma Non-melanocytic skin cancer Leukaemia Solid tumours, e.g. thyroid Cholangiocarcinoma following Thorotrast usage Lung cancer Medullary thyroid cancer Sarcoma
<b>Inflammatory diseases</b>	Ulcerative colitis	Colon cancer
<b>Hormonal</b>	Use of diethylstilbestrol Oestrogens	Vaginal cancer Endometrial cancer Breast cancer

(CT = computed tomography; MALT = mucosa-associated lymphoid tissue; UV = ultraviolet)

allows comparisons to be made between different groups of patients. One of the most commonly used systems is the T (tumour), N (regional lymph nodes), M (metastatic sites) approach of the International Union against Cancer (UICC, see [Box 7.3](#)). For most cancers staging will define patients into having:

- *early, localised disease*, which can be cured with surgery or other localised therapy (e.g. radiotherapy or ablative therapies)
- *locally advanced disease*, which can often be cured with a combination of surgery and/or systemic anti-cancer therapy and radiotherapy
- *metastatic disease*, where the cancer has spread to distant sites, which can only rarely be cured with systemic anti-cancer therapy, radiotherapy and/or surgery.

Imaging plays a critical role in the diagnosis and staging of cancer. It is also used to determine the response to treatment. The imaging modality employed depends primarily on the site of the disease and likely patterns of spread.

### Computed tomography

Computed tomography (CT) is a key investigation in cancer patients and is particularly useful in imaging the thorax and abdomen ([Fig. 7.5](#)). With

modern scanners it is possible to visualise the large bowel if it is prepared (CT colonography), allowing accurate detection of colorectal cancers and adenomas  $\geq 10$  mm.

### Ultrasound

Ultrasound is useful in characterising lesions within the liver, kidney, pancreas and reproductive organs. It may be used for guiding biopsies of tumours in the breast and liver. Endoscopic ultrasound is helpful in staging upper gastrointestinal and pancreatic cancers, involving a special endoscope with an ultrasound and biopsy probe attached.

### Magnetic resonance imaging

Magnetic resonance imaging (MRI) has a high resolution and is the preferred technique for brain, bone and pelvic imaging. It is widely employed for the staging of rectal, cervical and prostate cancers.

### Positron emission tomography

Positron emission tomography (PET) visualises metabolic activity of tumour cells and is often used in combination with CT (PET–CT) to evaluate the extent of the disease, particularly in the assessment of potential distant metastases when a radical treatment approach is being considered. Not all tumour types are 'PET-avid' and the metabolic activity of

## 7.2 Inherited cancer predisposition syndromes

Syndrome	Malignancies	Inheritance	Gene
Ataxia telangiectasia	Leukaemia, lymphoma, ovarian, gastric, brain, colon	AR	<i>AT</i>
Bloom syndrome	Leukaemia, tongue, oesophageal, colonic, Wilms' tumour	AR	<i>BLM</i>
Breast/ovarian	Breast, ovarian, colonic, prostatic, pancreatic	AD	<i>BRCA1, BRCA2</i>
Cowden syndrome	Breast, thyroid, gastrointestinal tract, pancreatic	AD	<i>PTEN</i>
Familial adenomatous polyposis	Colonic, upper gastrointestinal tract	AD	<i>APC, MUTYH</i>
Familial atypical multiple mole melanoma (FAMMM)	Melanoma, pancreas	AD	<i>CDKN2A (TP16)</i>
Fanconi anaemia	Leukaemia, oesophageal, skin, hepatoma	AR	<i>FACA, FACC, FACD</i>
Gorlin syndrome	Basal cell skin, brain	AD	<i>PTCH</i>
Hereditary diffuse gastric cancer	Diffuse gastric cancer	AD	<i>E-cadherin</i>
Hereditary non-polyposis colon cancer (HNPCC)	Colonic, endometrial, ovarian, pancreatic, gastric	AD	<i>MSH2, MLH1, MSH6, PMS1, PMS2</i>
Li–Fraumeni syndrome	Sarcoma, breast, osteosarcoma, leukaemia, glioma, adrenocortical	AD	<i>TP53</i>
Multiple endocrine neoplasia (MEN) 1	Pancreatic islet cell, pituitary adenoma, parathyroid adenoma and hyperplasia	AD	<i>MEN1</i>
MEN 2	Medullary thyroid, pheochromocytoma, parathyroid hyperplasia	AD	<i>RET</i>
Neurofibromatosis 1	Neurofibrosarcoma, pheochromocytoma, optic glioma	AD	<i>NF1</i>
Neurofibromatosis 2	Vestibular schwannoma	AD	<i>NF2</i>
Papillary renal cell cancer syndrome	Renal cell cancer	AD	<i>MET</i>
Peutz–Jegher syndrome	Colonic, ileal, breast, ovarian	AD	<i>STK11</i>
Prostate cancer	Prostate	AD	<i>HPC1</i>
Retinoblastoma	Retinoblastoma, osteosarcoma	AD	<i>RB1</i>
von Hippel–Lindau syndrome	Haemangioblastoma of retina and CNS, renal cell, pheochromocytoma	AD	<i>VHL</i>
Wilms' tumour	Nephroblastoma, neuroblastoma, hepatoblastoma, rhabdomyosarcoma	AD	<i>WT1</i>
Xeroderma pigmentosum	Skin, leukaemia, melanoma	AR	<i>XPA, XPC, XPD (ERCC2), XPF</i>

(AD = autosomal dominant; AR = autosomal recessive; CNS = central nervous system)

small but malignant lymph nodes may not be detected, limiting the sensitivity of PET-CT.

### Biochemical markers

Many cancers produce substances called tumour markers, some of which may assist in diagnosis, response evaluation and detection of relapse. Unfortunately, most tumour markers are neither sufficiently sensitive nor sufficiently specific to be used in isolation for diagnosis and need to be interpreted in the context of other clinical features. Some can be used for antibody-directed therapy or imaging, where they have a greater role in diagnosis. Tumour markers in routine use are outlined in [Box 7.4](#).

### Establishing the type of cancer

In most cases a biopsy is required in order to establish the tumour type. Biopsies can be taken at endoscopy, laparoscopy, surgery or by ultrasound- or CT- guided biopsy with the help of interventional radiology. At times a diagnosis can be obtained by examination of cells (cytology) from fluid (e.g. pleural or peritoneal), from a smear (e.g. cervical) or by doing fine needle aspiration of a palpable or visible lump ([Box 7.5](#)).

## 7.3 TNM classification

### Extent of primary tumour\*

TX	Not assessed
T0	No tumour
T1	
T2	Increase in primary tumour size or depth of invasion
T3	
T4	

### Increased involvement of nodes\*

NX	Not assessed
N0	No nodal involvement
N1	
N2/3	Increases in involvement

### Presence of metastases

MX	Not assessed
M0	Not present
M1	Present

\*Exact criteria for size and region of nodal involvement have been defined for each anatomical site.

**Fig. 7.5** Computed tomography (CT) images. **A** Extensive liver metastases in a patient with a high-grade neuro-endocrine cancer of unknown primary. **B** Repeat imaging after cytotoxic chemotherapy showing a partial radiological response to treatment. These remain stable 9 years later.

7.4 Commonly used serum tumour markers		
Name	Natural occurrence	Tumours
<b>Alpha-fetoprotein (AFP)</b>	Glycoprotein found in yolk sac and fetal liver tissue. Transient elevation in liver diseases. Has a role in screening during pregnancy for the detection of neural tube defects and Down syndrome	Ovarian non-seminomatous germ cell tumours (80%), testicular teratoma (80%), hepatocellular cancer (50%)
<b>Beta-2-microglobulin</b>	A human leucocyte antigen (HLA) common fragment present on surface of lymphocytes, macrophages and some epithelial cells. Can be elevated in autoimmune disease and renal glomerular disease	Non-Hodgkin lymphoma, myeloma
<b>Calcitonin</b>	32-amino-acid peptide from C cells of thyroid. Used to screen for MEN 2	Medullary cell carcinoma of thyroid
<b>Cancer antigen 125 (CA-125)</b>	Differentiation antigen of coelomic epithelium (Müller's duct). Raised in any cause of ascites, pleural effusion or heart failure. Can be raised in inflammatory conditions	Ovarian epithelial cancer (75%), gastrointestinal cancer (10%), lung cancer (5%) and breast cancer (5%)
<b>CA-19.9</b>	A mucin found in epithelium of fetal stomach, intestine and pancreas. It is eliminated exclusively via bile and so any degree of cholestasis can cause levels to rise	Pancreatic cancer (80%), mucinous tumour of the ovary (65%), gastric cancer (30%), colon cancer (30%)
<b>Carcinoembryonic antigen (CEA)</b>	Glycoprotein found in intestinal mucosa during embryonic and fetal life. Elevated in smokers, cirrhosis, chronic hepatitis, ulcerative colitis, pneumonia	Colorectal cancer, particularly with liver metastasis, gastric cancer, breast cancer, lung cancer, mucinous cancer of the ovary
<b>Human chorionic gonadotrophin (hCG)</b>	Glycoprotein hormone, 14 kD $\alpha$ subunit and 24 kD $\beta$ subunit from placental syncytiotrophoblasts. Used for disease monitoring in hydatidiform mole and as the basis of a pregnancy test	Choriocarcinoma (100%), hydatidiform moles (97%), ovarian non-seminomatous germ cell tumours (50%–80%), seminoma (15%)
<b>Placental alkaline phosphatase (PLAP)</b>	Isoenzyme of alkaline phosphatase	Seminoma (40%), ovarian dysgerminoma (50%)
<b>Prostate-specific antigen (PSA)</b>	Glycoprotein member of human kallikrein gene family. PSA is a serine protease that liquefies semen in excretory ducts of prostate. Can be elevated in benign prostatic hypertrophy and prostatitis	Prostate cancer (95%)
<b>Thyroglobulin</b>	Matrix protein for thyroid hormone synthesis in normal thyroid follicles	Papillary and follicular thyroid cancer

(MEN = multiple endocrine neoplasia)

## Histopathology

Histopathological analysis of tumour tissue is pivotal in identifying the type of cancer and provides information that may direct subsequent management. The results of histopathological analysis are most informative when combined with knowledge of the clinical picture; biopsy results should therefore be reviewed and discussed within the context of a multi-disciplinary team meeting.

## Light microscopy

Examination of tumour samples by light microscopy remains the core method of cancer diagnosis and, in cases where the primary site is unclear, may give clues to the origin of the tumour:

- Signet-ring cells favour a gastric primary.
- Presence of melanin favours melanoma.

### 7.5 How to perform a fine needle aspiration (FNA) of a tumour/lesion

- Ensure the patient is in a comfortable position with the lesion accessible to the operator.
- Identify the tumour, confirm that it is easily palpable and make sure there are no nearby critical structures.
- If tumour is not palpable or concern about nearby critical structures then perform FNA under ultrasound guidance.
- Clean the skin over the lesion.
- Inject local anaesthetic (if required) into the skin over the lesion.
- Label glass slide(s) and have ready near to the patient.
- Immobilise the lesion between thumb and forefinger of one hand.
- Introduce needle (usually with syringe attached) into lesion with the other hand.
- When the needle tip is at the edge of the lesion, apply negative pressure by pulling on the syringe and continue to enter the lesion.
- Make multiple rapid passes through the lesion, varying the angles if necessary.
- Stop sampling if blood is seen in the syringe hub as blood reduces the quality of the sample.
- Release the negative pressure while the needle is still in the lesion.
- Withdraw the needle and expel the cellular material from the needle onto the labelled glass slide(s) for pathological evaluation.

- Mucin is common in gut/lung/breast/endometrial and ovarian cancers.
- Psammoma bodies are a feature of ovarian cancer (mucin +) and thyroid cancer (mucin –).

### Immunohistochemistry

Immunohistochemical (IHC) staining for tumour markers can provide useful diagnostic information and may help with treatment decisions. Commonly used examples of IHC in clinical practice include:

- Oestrogen (ER) and progesterone (PR) receptor positivity indicate that the cancer may be sensitive to hormonal manipulation.
- Alpha-fetoprotein (AFP) and human chorionic gonadotrophin (hCG) favour germ-cell tumours.
- Prostate-specific antigen (PSA) favours prostate cancer.
- Cytokeratins and epithelial membrane antigen (EMA) favour epithelial carcinomas.
- HER2 receptor positivity in breast or gastric cancers indicate that the tumour may respond to HER2 inhibitor targeted therapy.
- T-cell receptor and cluster designation (CD) antigen expression aid in the diagnosis and classification of lymphomas.

### Molecular pathology

Molecular profiling of individual tumours is used to better understand their clinical behaviour and to stratify treatment options. Treatment selection is increasingly tailored to specific 'druggable' molecular pathways which include:

- *EGFR* mutations – predict response to EGFR inhibitor targeted therapy in lung cancer
- *RAS* mutations – predict resistance to EGFR inhibitor targeted therapy in colon cancer
- *ALK* fusion oncogene rearrangement – predict response to ALK inhibitor targeted therapy in lung cancer
- microsatellite instability – predict response to checkpoint inhibitor immunotherapy in several cancer types

### Cytogenetic analysis

Some tumours demonstrate typical chromosomal changes that help in diagnosis. The utilisation of fluorescent in situ hybridisation (FISH) techniques can be useful in Ewing's sarcoma and peripheral neuro-ectodermal

### 7.6 Eastern Cooperative Oncology Group (ECOG) performance status scale

0	Fully active, able to carry on all usual activities without restriction and without the aid of analgesics
1	Restricted in strenuous activity but ambulatory and able to carry out light work or pursue a sedentary occupation. This group also contains patients who are fully active, as in grade 0, but only with the aid of analgesics
2	Ambulatory and capable of all self-care but unable to work. Up and about more than 50% of waking hours
3	Capable of only limited self-care, confined to bed or chair more than 50% of waking hours
4	Completely disabled, unable to carry out any self-care and confined totally to bed or chair

### 7.7 Cancer in old age

- **Incidence:** around 50% of cancers occur in the 15% of the population aged over 65 years.
- **Screening:** women over 65 in the UK are not invited to breast cancer screening but can request it. Uptake is low despite increasing incidence with age.
- **Presentation:** may be later for some cancers. When symptoms are non-specific, patients (and their doctors) may initially attribute them to age alone.
- **Life expectancy:** an 80-year-old woman can expect to live 8 years, so cancer may still shorten life and an active approach remains appropriate.
- **Prognosis:** histology, stage at presentation and observation for a brief period are better guides to outcome than age.
- **Rate of progression:** malignancy may have a more indolent course. This is poorly understood but may be due to reduced effectiveness of angiogenesis with age, inhibiting the development of metastases.
- **Response to treatment:** equivalent to that in younger people – well documented for a range of cancers and for surgery, radiotherapy, cytotoxic chemotherapy and hormonal therapy.
- **Toxicity of treatment:** may be greater due to subclinically reduced baseline hepatic, renal and bone marrow function and reduced baseline energy.
- **Treatment selection:** chronological age is of minor importance compared to comorbid illness and patient choice. Although older patients can be treated effectively and safely, aggressive intervention is not appropriate for all. Symptom control may be all that is possible or desired by the patient.

tumours where there is a translocation between chromosome 11 and 22: t(11;22)(q24;q12). In some cases, gene amplification can be detected via FISH (e.g. determining over-expression of HER2/neu).

### Assessing fitness

When making decisions about investigations and management in patients with cancer it is important to consider an individual's general condition and comorbidities. The Eastern Cooperative Oncology Group (ECOG) performance status (PS) scale is used to formally assess a patient's fitness (Box 7.6). Outcomes for patients with PS 3–4 are worse in almost all malignancies than for those with PS 0–2, and this has a strong influence on the approach to treatment in the individual patient. Additionally, outcomes are typically worse for patients with a low albumin and raised inflammatory markers (i.e. white blood cell count, C-reactive protein). Comorbidities also frequently influence treatment options. For example, hepatic or renal dysfunction means some systemic therapies cannot be used or can only be given in lower doses. In some patients poor fitness or comorbidities may preclude any anti-cancer therapy options, in which case comprehensive diagnostic and staging investigations add little clinical value and may not be in the best interests of the patient.

Although the incidence of cancer increases with patient age, the approach to investigation and management is similar at all ages (Box 7.7). However, assessing fitness in this group of patients can be difficult, with

### 7.8 Specific roles of the cancer multidisciplinary team (MDT)

- Agreeing on cancer type and final stage.
- Deciding on the appropriate primary treatment modality (most commonly surgery but the use of neoadjuvant systemic anti-cancer therapy and/or radiotherapy before surgery is increasing).
- Arranging review by the appropriate team to coordinate management.
- Planning surveillance strategies.
- Diagnosing cancer recurrence or metastases.
- Ensuring the appropriate transition from treatment with curative intent to that of palliation.
- Promoting recruitment into clinical trials.
- Agreeing on operational policies to deliver high-quality care to patients.
- Planning and reviewing audit data to ensure delivery of quality care to patients.
- Identifying late effects of cancer treatments.

increasing comorbidity and declining physiological reserve in particular placing patients at increased risk of treatment toxicity. Geriatric assessment tools to assess patient fitness and toxicity risks have been developed.

## Multidisciplinary teams

The multidisciplinary team (MDT) is well established in oncology and meets on a regular basis to discuss patient progress and provide a forum for patient-centred, interdisciplinary communication to coordinate care and decision-making. It is a platform on which individual clinicians can discuss complex cases or situations and draw on the collective experience of the team membership to decide on the best approach for an individual patient. This can be particularly important when discussing patients with a rare condition or in an unusual situation. As a minimum, most MDTs include a radiologist, pathologist, specialist physician, specialist surgeon, radiation oncologist, medical oncologist, nurse specialist, auditor and scheduler. Additional staff may be relevant to different MDTs, e.g. dermatologists in skin cancer MDTs, dieticians in upper gastrointestinal cancer MDTs, stoma nurses in colorectal cancer MDTs, palliative care doctors in pancreatic cancer or cancer of unknown primary (CUP) MDTs. Specific roles of the MDT are outlined in [Box 7.8](#).

## Acute oncology

Cancer centres are usually based in cities and have busy radiotherapy and systemic anti-cancer therapy units containing specialist equipment and teams of highly trained physicians, surgeons, nurses, pharmacists, radiographers, physicists and support workers amongst others. Most patients with cancer undergo investigations, assessments and treatment as outpatients. However, patients may present acutely to any specialty in any hospital with a new cancer, cancer-related symptoms, emergency complications of cancer or with treatment-related toxicities.

## Acute presentation of new cancer

Despite cancer screening initiatives, most patients still present with symptomatic disease. They may have symptoms related to the local effect of a primary tumour or metastatic deposit, such as finding a lump, dysphagia or persistent pain. These are sometimes called ‘red flag’ symptoms of cancer ([Box 7.9](#)). Patients may present with constitutional symptoms such as unexplained weight loss, fatigue or fevers. Paraneoplastic syndromes due to the production of biologically active hormones by the tumour, or as the result of an immune response to the tumour, may also be the presenting symptom of new cancer ([Box 7.10](#)). The pattern of

### 7.9 Red flag symptoms of malignancy

Symptom	Typical site or possible tumour
Lump	Breast, lymph node (any site), testicle
Skin abnormality	Melanoma, basal cell carcinoma
Bleeding	Stomach, colon, lung, endometrium, bladder, kidney
Dysphagia, odynophagia	Oesophagus, bronchus, gastric, head and neck
Change in bowel habit	Colon, rectum, ovary
Cough, hoarseness, stridor	Lung, head and neck, thyroid
Bone pain or fracture	Bone (primary sarcoma, secondary metastasis from breast, prostate, bronchus, thyroid, kidney)
Abdominal swelling (ascites)	Ovary, stomach, pancreas
Unexplained weight loss, anorexia	Lung, gastrointestinal tract, CUP
Unexplained fatigue	Any

(CUP = cancer of unknown primary)

### 7.10 Paraneoplastic syndromes

Feature	Common cancer site associations
Lambert–Eaton myasthenic syndrome	Small cell lung cancer
Subacute cerebellar degeneration	Small cell lung cancer, ovarian cancer
Encephalomyelitis	Small cell lung cancer
Retinopathy	Non-small cell lung cancer
Dermatomyositis/polymyositis	Gastric, lung cancer
Acanthosis nigricans	Gastric, oesophageal cancer
Vitiligo	Melanoma
Pruritus	Lymphoma, leukaemia, central nervous system tumours
Pemphigus	Lymphoma, Kaposi's sarcoma, thymic
Dermatitis herpetiformis	Enteropathy-associated T-cell lymphoma (EATL)

symptoms, detailed clinical history and examination will most often direct the initial investigations and early referral to the appropriate specialist multidisciplinary team.

## Cancer of unknown primary (CUP)

When a patient is found to have advanced or metastatic cancer but history, examination and imaging is unable to define a primary cancer site, an assessment of patient fitness, disease extent, comorbidities and patient wishes should be made. Selected investigations should be carried out ([Box 7.11](#)). However, a primary cancer site does not need to be ‘hunted down’ in all patients and investigations should be limited to those that will help management. Specialist investigations (e.g. endoscopies) are only indicated when there is radiological suspicion or if there are localising symptoms.

In some cases, such as those with clinical suspicion of germ cell tumours, high-grade lymphoma or small cell cancer, or those presenting with oncological emergencies, urgent referral directly to oncology or haematology is essential to allow rapid initiation of anti-cancer therapy, sometimes before investigations are completed ([Fig. 7.6](#)).

If patients are fit to undergo investigations and fit enough to be considered for treatment then a core biopsy of the most accessible metastatic

### 7.11 Initial diagnostic tests in patients presenting with carcinoma of unknown primary

- Detailed medical history and examination, including breast, nodal areas, skin, genital, rectal and pelvic regions
- Full blood count, urea and electrolytes, renal function, liver function tests, albumin, calcium, urinalysis, lactate dehydrogenase, CRP
- Myeloma screen (if lytic bone lesions)
- CT scan of chest, abdomen and pelvis
- CT neck if thyroid lump or neck nodes
- Histological examination by biopsy, with immunohistochemistry and/or molecular pathology if required
- Upper or lower gastrointestinal endoscopy if gastrointestinal symptoms
- Mammography and/or breast MRI for women with axillary nodes or adenocarcinoma
- Breast MRI for women with adenocarcinoma limited to axillary nodes
- Testicular ultrasound (if midline disease in young man or clinical features suggest germ cell tumour)
- Naso-endoscopy for squamous neck nodes
- PET scan for single-site disease or squamous neck nodes with no primary on endoscopic evaluation
- Tumour markers: prostate-specific antigen (PSA) in men with bone lesions, cancer antigen 125 (CA-125) in women with peritoneal malignancy or ascites,  $\alpha$ -fetoprotein (AFP) in liver-limited disease,  $\alpha$ -fetoprotein (AFP) and human chorionic gonadotrophin (hCG) in midline disease in young men

(CRP = C-reactive protein; CT = computed tomography; MRI = magnetic resonance imaging; PET = positron emission tomography)

**Fig. 7.6** Young male patient presenting with a bulky midline tumour and elevated hCG and AFP suggestive of a non-seminomatous testicular cancer.

lesion is usually the quickest way of obtaining tissue for pathological evaluation of cancer type. Review of tumour morphology, immunohistochemistry and molecular pathology will usually be sufficient to plan appropriate treatment. Patients with clinico-pathological features suggestive of a particular cancer should be identified early and referred promptly to the appropriate multidisciplinary/oncology team for consideration of further investigations and treatment. Where the primary site remains unclear following comprehensive investigations, a patient is said to have a cancer of unknown primary (CUP).

Whilst it is crucial to identify patients with highly treatable CUPs (Box 7.12), some of whom can live for years (see Fig. 7.5), or even be cured by treatment, most CUPs are poorly differentiated cancers or adenocarcinomas with liver and/or multi-site metastases. These cancers often behave aggressively so early discussion with oncology, within the context of a specialist MDT, is essential to streamline investigations and assess fitness for anti-cancer treatment. Whilst responses to generic systemic anti-cancer treatment are modest, gene expression tests or molecular tumour profiling are increasingly providing greater information about likely tissue of origin or possible treatment targets which may ultimately lead to improved understanding of CUP and better outcomes.

### 7.12 Cancer of unknown primary – favourable clinicopathological features

Clinicopathological features	Management
Women with serous papillary adenocarcinoma of the peritoneal cavity	Treat like ovarian cancer
Women with isolated adenocarcinoma of axillary lymph nodes	Treat like breast cancer
Men with poorly differentiated carcinoma with midline distribution	Treat like germ cell cancer
Poorly differentiated neuro-endocrine carcinoma of unknown origin	Treat like small cell cancer
Well-differentiated neuro-endocrine tumour (NET)	Treat with somatostatin analogues or as per NETs of known primary sites
Squamous cell carcinoma of non-supraclavicular cervical lymph nodes	Treat like head and neck squamous cell cancer
Adenocarcinoma with a colorectal-IHC profile (CK20+, CK7-, CDX2+)	Treat like colon cancer
Men with blastic bone metastases or elevated prostate-specific antigen (adenocarcinoma)	Treat like prostate cancer
Isolated inguinal adenopathy squamous carcinoma	Treat like anogenital squamous cancer
Patients with one small, potentially resectable tumour	Assess for surgical resection

### Metastatic malignant disease of undefined primary origin (MUO)

Patients who present as emergencies to hospital with symptomatic new metastatic cancer often have a short prognosis. Features associated with poor prognosis, irrespective of subsequent diagnosis, include: poor performance status (PS 3–4), requirement for hospital admission, bulky or multi-organ metastatic disease, significant comorbidity, raised LDH, raised inflammatory markers and low albumin. Further investigations, including biopsy, may not be warranted and honest conversations about palliative care and end-of-life planning are often preferable. Appropriate analgesia, palliative radiotherapy (for bleeding or pain) and interventional/surgical palliation can all help improve symptoms.

### Oncological emergencies

Oncological emergencies are a group of potentially life-threatening conditions that occur as a direct result of cancer or its treatment. Positive outcomes depend upon prompt recognition and implementation of appropriate management.

### Malignant spinal cord compression

Malignant spinal cord compression complicates 5% of cancers and is most common in myeloma, prostate, breast and lung cancers that most frequently involve bone. Malignant spinal cord compression often results from posterior extension of a vertebral body mass but intrathecal spinal cord metastases can cause similar signs and symptoms. The thoracic region is most commonly affected (Fig. 7.7).

### Clinical features

The earliest sign is back pain, often rapidly worsening or in a 'band', most marked on coughing and lying flat. Subsequently, sensory changes develop in dermatomes below the level of compression, and motor weakness distal to the block occurs. Finally, sphincter disturbance, causing urinary retention and bowel incontinence, is observed.

**Fig. 7.7** MRI images of patient presenting with back pain and lower limb neurological disturbance. **A** Normal appearances of spinal cord. **B** Metastatic disease arising from thoracic vertebra compressing spinal cord.

### **i** 7.13 Comparison of features of neurological deficit

Clinical feature	Spinal cord	Conus medullaris	Cauda equina
<b>Weakness</b>	Symmetrical and profound	Symmetrical and variable	Asymmetrical, may be mild
<b>Reflexes</b>	Increased (or absent) knee and ankle reflexes with extensor plantar reflex	Increased knee reflex, decreased ankle reflex, extensor plantar reflex	Decreased knee and ankle reflexes with flexor plantar reflex
<b>Sensory loss</b>	Symmetrical, sensory level	Symmetrical, saddle distribution	Asymmetrical, radicular pattern
<b>Sphincters</b>	Late loss	Early loss	Often spared
<b>Progression</b>	Rapid	Variable	Variable

Involvement of the lumbar spine may cause conus medullaris or cauda equina compression (Box 7.13). Physical examination findings consistent with an upper motor neuron lesion, but lower motor neuron findings, may predominate early on or in cases of nerve root or cauda equina compression.

#### **Management**

Malignant spinal cord compression is a medical emergency and should be treated with analgesia and high-dose glucocorticoid therapy (Box 7.14). Neurosurgical intervention produces superior outcomes and survival compared to radiotherapy alone, and should be considered first for all patients. It is the preferred treatment if there is a single site of disease, low volume metastatic disease, if a biopsy is required to make a diagnosis or if it is a treatable cancer (e.g. lymphoma, breast cancer). Radiotherapy is used for the remaining patients and selected tumour

### **7.14 Management of suspected spinal cord compression**

- Confirm diagnosis with urgent MRI scan of whole spine
- Administer high-dose glucocorticoids:  
Dexamethasone 16 mg IV or oral stat  
Dexamethasone 8 mg twice daily orally
- Ensure adequate analgesia
- Refer for surgical decompression or urgent radiotherapy

(IV = intravenous; MRI – magnetic resonance imaging)

types when the cancer is likely to be radiosensitive. The prognosis varies considerably, depending on tumour type, but the degree of neurological dysfunction at presentation is the strongest predictor of outcome, irrespective of the underlying diagnosis. Mobility can be preserved in more

than 80% of patients who are ambulatory at presentation, but neurological function is seldom regained in patients with established deficits such as paraplegia.

## Superior vena cava obstruction

Superior vena cava obstruction (SVCO) is a common complication of cancer that can occur through extrinsic compression or intravascular blockage. The most common causes of extrinsic compression are lung cancer, lymphoma and metastatic tumours (Fig. 7.8). Patients with cancer can also develop SVCO due to intravascular blockage in association with a central catheter or thromboembolism secondary to the tumour.

### Clinical features

The classical presentation is with breathlessness, oedema of the arms and face, distended neck and arm veins and dusky skin coloration over the chest, arms and face. Collateral vessels may develop over a period of weeks and the flow of blood in the collaterals helps to confirm the diagnosis. Headache secondary to cerebral oedema arising from the back-flow pressure may also occur and tends to be aggravated by bending forwards, stooping or lying down. The severity of symptoms is related to the rate of obstruction and the development of a venous collateral circulation. Accordingly, symptoms may develop rapidly or gradually. Clinical features are summarised in Box 7.15.

### Investigations and management

The investigation of choice is a CT scan of the thorax to confirm the diagnosis and distinguish between extra- and intravascular causes.

A biopsy should be obtained when the tumour type is unknown because tumour type has a major influence on treatment. CT of the

**Fig. 7.8** Computed tomography (CT) image of extrinsic compression of the superior vena cava by a small cell lung cancer (arrow) performed as part of investigations for an acute presentation of cancer.

### 7.15 Common symptoms and physical findings in superior vena cava obstruction\*

#### Symptoms

- Dyspnoea (63%)
- Facial swelling and head fullness (50%)
- Cough (24%)
- Arm swelling (18%)
- Chest pain (15%)
- Dysphagia (9%)

#### Physical findings

- Venous distension of neck (66%)
- Venous distension of chest wall (54%)
- Elevated, non-pulsatile jugular venous pulse (66%)
- Facial oedema (46%)
- Cyanosis (20%)
- Plethora of face (19%)
- Oedema of arms (14%)

\*Percentage of patients affected.

head may be indicated if cerebral oedema is suspected. Tumours that are exquisitely sensitive to cytotoxic chemotherapy, such as germ cell tumours and lymphoma, can be treated with cytotoxic chemotherapy alone. For most other patients with symptomatic SVCO, SVC stenting provides the best outcomes although mediastinal radiotherapy may also be considered. Where possible, these measures should be followed by treatment of the primary tumour, as long-term outcome is strongly dependent on the prognosis of the underlying cancer.

## Neutropenic fever

Neutropenia is a common complication of malignancy. It is usually secondary to cytotoxic chemotherapy but may occur with radiotherapy, if large amounts of bone marrow are irradiated, and some targeted therapy agents; it may also be a component of pancytopenia due to malignant infiltration of the bone marrow. After cytotoxic chemotherapy neutropenic fever is most commonly defined as a single oral temperature of  $\geq 38.3^{\circ}\text{C}$  or a temperature of  $\geq 38^{\circ}\text{C}$  sustained for over 1 hour in a patient with a neutrophil count of  $<0.5 \times 10^9/\text{L}$  (or  $<1.0 \times 10^9/\text{L}$  if the nadir is anticipated to drop to  $<0.5 \times 10^9/\text{L}$  in the next 48 hours). The risk of sepsis is greater with profound neutropenia (neutrophil count  $<0.1 \times 10^9/\text{L}$ ), prolonged neutropenia ( $<0.5$  neutrophils for  $\geq 7$  days) or a rapid rate of decline in neutrophils as well as the presence of other risk factors, such as intravenous cannulae or urinary catheters. Neutropenic fever is an emergency in cancer patients as, if left untreated, it can result in sepsis with a high mortality rate.

### Clinical features

The typical presentation is with high fever, and affected patients may feel non-specifically unwell. If patients have been taking paracetamol or steroids then fever or symptoms may be masked. Examination is usually unhelpful in defining a primary source of the infection. Hypotension is an adverse prognostic feature and may progress to systemic circulatory shutdown and organ failure.

### Investigations and management

An infection screen should be performed, including blood cultures (both peripheral and from central lines), urine culture, chest X-ray and swabs for culture (throat, central line, wound). High-dose intravenous antibiotics should be commenced (ideally within 1 hour of admission) for all febrile patients on systemic anti-cancer therapy, without awaiting test results. The standard approach is to commence empirical broad-spectrum antibiotics according to local hospital policies agreed with microbiologists and based on local antibiotic resistance patterns. Depending on the patient's MASCC risk index score (Box 7.16) and likely organisms this

### 7.16 MASCC\* risk index score for neutropenic fever

Characteristic	Score
Burden of current illness	
No or mild symptoms (normal function)	5
Moderate symptoms (uncomfortable or influences daily activities)	3
Severe symptoms (significant discomfort or limits daily activities)	0
No hypotension (systolic BP $> 90$ mmHg)	5
No chronic obstructive pulmonary disease	4
Solid tumour or lymphoma with no previous fungal infection	4
No dehydration requiring parenteral fluids	3
Outpatient at onset of fever	3
Age $<60$ years	2
Score $\geq 21$ = low risk febrile neutropenia Score $<21$ = high risk febrile neutropenia	

\*Multinational Association of Supportive Care in Cancer.

may be either monotherapy (e.g. piperacillin–tazobactam or meropenem) or combination therapy (e.g. with the addition of gentamicin if high risk on MASCC score, metronidazole if anaerobic infection is suspected, or vancomycin/teicoplanin where Gram-positive infection is suspected). Antibiotics should be adjusted according to culture results, although these are often negative. If there is no clinical improvement after 36–48 hours antibiotics should be reviewed with microbiological advice, and antifungal cover should be considered (e.g. fluconazole or liposomal amphotericin B). Granulocyte–colony-stimulating factor (G-CSF) can be used to hasten neutrophil recovery in some patients with febrile neutropenia, in line with local guidelines. Other supportive therapy, including intravenous fluids, oxygen, inotrope therapy, ventilation or haemofiltration, may be required.

## Hypercalcaemia of malignancy

Hypercalcaemia is the most common metabolic disorder in patients with cancer and has a prevalence of up to 20% in cancer patients. The incidence is highest in myeloma and breast cancer (approximately 40%), intermediate in non-small cell lung cancer, and uncommon in colon, prostate and small cell lung carcinomas. It is most commonly due to over-production of PTHrP (80%), which binds to the PTH receptor and elevates serum calcium by stimulating osteoclastic bone resorption and increasing renal tubular reabsorption of calcium. Direct invasion of bone by metastases accounts for around 20% of cases while other mechanisms, such as ectopic PTH secretion, are rare.

### Clinical features

The symptoms of hypercalcaemia are often non-specific and may mimic those of the underlying malignancy. They include drowsiness, delirium, nausea and vomiting, constipation, polyuria, polydipsia and dehydration.

### Investigations and management

The diagnosis is made by measuring serum total calcium and adjusting for albumin. It is especially important to correct for albumin in cancer because hypoalbuminaemia is common and total calcium values under-estimate the level of ionised calcium. The principles of management are outlined in [Box 7.17](#).

Patients should initially be treated with intravenous 0.9% saline to improve renal function and increase urinary calcium excretion. This alone often results in clinical improvement. Concurrently, intravenous bisphosphonates should be given to inhibit bone resorption. Calcitonin acts rapidly to increase calcium excretion and to reduce bone resorption, and can be combined with fluid and bisphosphonate therapy for the first 24–48 hours in patients with life-threatening hypercalcaemia. Bisphosphonates will usually reduce the serum calcium levels to normal within 5 days, but, if not, treatment can be repeated. The duration of action is up to 4 weeks and repeated therapy can be given at 3–4-weekly intervals in the outpatient department. Hypercalcaemia is frequently a sign of tumour progression and the patient requires further investigation to establish disease status and review the anti-cancer treatment strategy.

## Immune-related adverse events

Immunotherapy has revolutionised the treatment of many cancers (see ‘Immunotherapy’ below). Checkpoint inhibitor immunotherapy, in

### 7.17 Medical management of severe hypercalcaemia

- IV 0.9% saline 2–4L/day
- Zoledronic acid 4 mg IV or pamidronate 60–90 mg IV
- For patients with severe, symptomatic hypercalcaemia that is refractory to zoledronic acid, denosumab (initial dose 60 mg SC, with repeat dosing based on response) is an alternative option

(IV = intravenous; SC = subcutaneous)

particular, is now widely used in the treatment of many different cancers. Side-effects of checkpoint inhibitor immunotherapy agents occur when the immune system is stimulated to attack healthy cells and tissues in the body. These immune-related adverse events (IRAEs) are increasingly being recognized as oncological emergencies.

### Clinical features

Almost any body system may be affected, but inflammation of the colon, endocrine organs (thyroid, adrenal and pituitary glands) lungs, liver, skin and nervous system are most frequently seen (see p. 129). IRAEs may occur at any point in a patient’s treatment, or even after they have stopped receiving the checkpoint inhibitor immunotherapy agent.

### Investigations and management

Investigation and management of IRAEs requires a multidisciplinary approach including oncologists and relevant system specialists. Specialist investigations may be required depending on the body system affected. The focus of treatment is on dampening the immune response, often using high-dose steroids. Additional immunosuppressant therapies are sometimes required. In the case of endocrine organ inflammation, replacement of deficient hormones is also important. In patients who experience severe IRAEs, checkpoint inhibitor immunotherapy treatment will usually be permanently discontinued. In other cases, and in patients with endocrine IRAEs who commence replacement hormone therapy, it may be possible to reintroduce checkpoint inhibitor immunotherapy treatment.

## Tumour lysis syndrome

The acute destruction of a large number of cells can be associated with metabolic sequelae and is called tumour lysis syndrome. It is usually related to bulky, chemosensitive disease, including lymphoma, leukaemia and germ cell tumours. More rarely, it can occur spontaneously.

### Clinical features

Cellular destruction results in the release of potassium, phosphate, nucleic acids and purines that can cause transient hypocalcaemia, hyperphosphataemia, hyperuricaemia and hyperkalaemia. This can lead to acute impairment of renal function and the precipitation of uric acid crystals in the renal tubular system. These can manifest with symptoms associated with multiple underlying electrolyte abnormalities, including fatigue, nausea, vomiting, cardiac arrhythmia, heart failure, syncope, tetany, seizures and sudden death.

### Investigations and management

Serum biochemistry should be monitored regularly for 48–72 hours after treatment in patients at risk. Elevated serum potassium may be the earliest biochemical marker but pre-treatment serum lactate dehydrogenase (LDH) correlates with tumour bulk and may indicate increased risk. Good hydration and urine output should be maintained throughout treatment administration. Prophylaxis with allopurinol should be considered and recombinant urate oxidase (rasburicase) can be used to reduce uric acid levels when other treatments fail. Adequate hydration is vital, as it has a dilution effect on the extracellular fluid, improving electrolyte imbalance, and increases circulating volume, improving filtration in the kidneys. In high-risk patients, hydration and rasburicase should be commenced 24 hours before the start of treatment. If normal treatment methods fail to correct the problems, haemodialysis should be considered at an early stage to prevent progression to irreversibility.

## Other acute presentations in oncology

### Venous thromboembolism

Venous thromboembolism (VTE) is the second leading cause of death amongst patients with cancer. Malignancy is a strong risk factor for

VTE and may be the first presenting feature of an underlying cancer. Several mechanisms lead to a prothrombotic state in cancer. This includes the ability of cancer cells to produce procoagulant/fibrinolytic substances and inflammatory cytokines and the physical interaction between tumour cells and blood (monocytes, neutrophils, platelets) or endothelial cells. Anti-cancer therapy (i.e. surgery, cytotoxic chemotherapy, hormone therapy and radiotherapy) and any in-dwelling access devices (i.e. central venous catheters) further increase the risk. As in patients without cancer, the management of cancer-associated VTE primarily involves anticoagulation therapy. However, the choice of therapy must take into account bleeding risk and possible interactions with anti-cancer therapies and their side-effects, such as thrombocytopenia. In patients with metastatic cancer, anticoagulation therapy will often be lifelong.

### Ectopic hormone production

Some cancers are associated with metabolic abnormalities due to ectopic production of hormones by tumour cells, including insulin, ACTH, vasopressin (antidiuretic hormone, ADH), fibroblast growth factor (FGF)-23, erythropoietin and parathyroid hormone-related protein (PTHrP). This can result in a wide variety of presentations, as summarised in [Box 7.18](#).

### Neurological paraneoplastic syndromes

These form a group of conditions associated with cancer that are thought to be due to an immunological response to the tumour that results in damage to the nervous system or muscle (see [Box 7.10](#)). The cancers most commonly implicated are those of the lung, pancreas, breast, prostate, ovary and lymphoma. Many are associated with specific detectable immune biomarkers such as antibodies to pre-synaptic calcium channels (Lambert–Eaton syndrome), anti-Hu antibodies (encephalomyelitis) and anti-Yo or anti-Tr antibodies (cerebellar degeneration). However, these are not always specific and negative results do not exclude the diagnosis. The management of these syndromes is multidisciplinary and includes treatment of the underlying cancer itself and treatment of the syndrome primarily with immunosuppressive agents.

### Cutaneous manifestations of cancer

Cancers can present with skin manifestations that are not due to metastases (see [Box 7.10](#)). The clinical features and management of these skin conditions are discussed in [Chapter 27](#).

#### 7.18 Ectopic hormone production by tumours

Hormone	Consequence	Tumours
ACTH	Cushing's syndrome	SCLC
Erythropoietin	Polycythaemia	Kidney, HCC, cerebellar haemangioblastoma, uterine fibroids
FGF-23	Hypophosphataemic osteomalacia	Mesenchymal tumours
PTHrP	Hypercalcaemia	NSCLC (squamous cell), breast, kidney
Vasopressin (ADH)	Hyponatraemia	SCLC

(ACTH = adrenocorticotropic hormone; ADH = antidiuretic hormone; FGF = fibroblast growth factor; HCC = hepatocellular carcinoma; NSCLC = non-small cell lung cancer; PTHrP = parathyroid hormone-related protein; SCLC = small cell lung cancer)

## Symptoms from locally advanced cancer or metastatic sites

Metastatic disease is the major cause of death in cancer patients and the principal cause of morbidity. For the majority of patients with metastatic disease the goal of treatment is to control cancer, maintain quality of life, treat symptoms and prolong life (i.e. 'palliative treatment'). Patients of PS 3–4 ([Box 7.6](#)) or with low albumin plus high inflammatory markers often have a limited prognosis irrespective of anti-cancer treatments. Systemic anti-cancer therapies have resulted in improved survival for many cancers so that some patients live a good quality life for many years with metastatic cancer. Treatment of a solitary metastasis or highly treatable cancers (e.g. germ cell) can be curative.

### Brain metastases

Brain metastases occur in 10%–30% of adults and 6%–10% of children with cancer and are an increasingly important cause of morbidity. Cancers of lung, breast, melanoma and gastrointestinal tract most commonly metastasise to the brain. Most involve the brain parenchyma but can also affect the meninges, cranial nerves, the blood vessels and other intracranial structures. In cases of solitary metastasis to the brain, the use of surgery followed by adjuvant radiotherapy, or alternatively stereotactic radiotherapy, has been shown to increase survival in patients whose disease is otherwise controlled. Outcomes for patients with more advanced brain metastases depends on the primary cancer, extent of extracranial disease and what systemic treatment options are available. For patients with advanced untreatable cancer and multiple brain metastases, prognosis is often short. Glucocorticoids can improve symptoms, particularly where there is evidence of peri-lesional oedema. In treatable cancers whole brain radiotherapy can allow steroid dose to be reduced whilst systemic therapy is used to treat the remaining cancer. With improved systemic therapies, including targeted therapies and immunotherapy, some patients are now living for several years with brain metastases.

#### Clinical features

Presentation is with headaches and nausea (40%–50%), focal neurological dysfunction (20%–40%), cognitive dysfunction (35%), seizures (10%–20%) and papilloedema (<10%).

#### Investigations and management

The diagnosis can be confirmed by CT or contrast-enhanced MRI. Treatment options include high-dose glucocorticoids for tumour-associated oedema (dexamethasone 4–12 mg daily depending on amount of oedema), anticonvulsants for seizures, whole-brain radiotherapy and systemic anti-cancer therapy. Surgery may be considered for single sites of disease and can be curative; stereotactic radiotherapy may also be considered for solitary site involvement or where surgery is more difficult or not possible.

### Lung metastases

Lung metastases are common in breast cancer, colon cancer, renal cancer, sarcoma and tumours of the head and neck. The presentation is usually with a lesion on chest X-ray or CT. Solitary lesions require investigation, as single metastases can be difficult to distinguish from a primary lung tumour. Patients with two or more pulmonary nodules can be assumed to have metastases. The approach to treatment depends on the extent of disease in the lung and elsewhere. For solitary lesions, surgery should be considered, with a generous wedge resection, or radiofrequency ablation if available. Radiotherapy and systemic anti-cancer therapies can be used, dependent on the underlying primary cancer diagnosis ([Fig. 7.9](#)).

### Liver metastases

Metastatic cancer in the liver can represent the sole or life-limiting component of disease for many with colorectal cancer, ocular melanoma,

**Fig. 7.9** **A** Chest X-ray and **B** computed tomography (CT) images of diffuse metastatic lung lesions in a symptomatic patient.

neuro-endocrine tumours (NETs) and, less commonly, other tumour types. The most common clinical presentations are with right upper quadrant pain due to stretching of the liver capsule, jaundice, deranged liver function tests or an abnormality detected on imaging. In selected cases, resection of the metastasis can be contemplated. In colorectal cancer, successful resection of metastases improves 5-year survival from 3% to 30%–40%. Other techniques, such as chemoembolisation, radio-frequency ablation or microwave ablation, can also be used, provided the number and size of metastases remain small. If these are not feasible, symptoms may respond to systemic anti-cancer therapy (Fig. 7.5).

## Bone metastases

Bone is the third most common organ involved by metastasis, after lung and liver. Bone metastases are a major clinical problem in patients with myeloma and breast or prostate cancers, but other tumours that commonly metastasise to bone include those of the kidney and thyroid. Bone metastases are increasingly seen in other tumour types that do not classically target bone, due to effective anti-cancer treatments prolonging survival of patients with many cancers. Accordingly, effective management of bony metastases has become a focus in the treatment of patients with many incurable cancers.

### Clinical features

The main presentations are with pain, pathological fractures, spinal cord compression (see above) and hypercalcaemia. Pain tends to be progressive and worst at night, and may be partially relieved by activity, but subsequently becomes more constant in nature and is exacerbated by movement. Most pathological fractures occur in metastatic breast cancer (53%); other tumour types associated with fracture include the kidney (11%), lung (8%), thyroid (5%), lymphoma (5%) and prostate (3%).

### Investigations and management

The most sensitive way of detecting bone metastases is by isotope bone scan. This can have false-positive results in healing bone, particularly as a flare response following treatment and false-negative results occur in multiple myeloma due to suppression of osteoblast activity. Plain X-ray films or MRI scans are therefore preferred for any sites of bone pain, as lytic lesions may not be detected by a bone scan. In patients with a single lesion, it is especially important to perform a biopsy to obtain a tissue diagnosis, since primary bone tumours may look very similar to metastases on X-ray. The main goals of management are:

- pain relief
- preservation and restoration of function

- skeletal stabilisation
- local tumour control (e.g. relief of tumour impingement on normal structure).

Surgical intervention may be warranted where there is evidence of skeletal instability (e.g. anterior or posterior spinal column fracture) or an impending fracture (e.g. a large lytic lesion on a weight-bearing bone with more than 50% cortical involvement). Intravenous bisphosphonates (pamidronate, zoledronic acid or denosumab) are widely used for bone metastases and are effective at improving pain and in reducing further skeletal related events, such as fractures and hypercalcaemia. In certain types of cancer, such as breast and prostate, hormonal therapy may be effective. Radiotherapy, in the form of external beam therapy or systemic radionuclides (strontium treatment), can also help pain. In some settings (e.g. breast carcinoma), systemic anti-cancer therapy may be used in the management of bony metastases.

## Malignant pleural effusion

This is a common complication of cancer and 40% of all pleural effusions are due to malignancy. The most common causes are lung and breast cancers, and the presence of an effusion indicates incurable disease. The presentation may be with dyspnoea, cough or chest discomfort, which can be dull or pleuritic in nature. Diagnosis and management of pleural effusion is discussed on page 494.

### Investigations and management

Pleural aspirate is the key investigation and may show the presence of malignant cells. Malignant effusions are commonly blood-stained and are exudates with a raised fluid to serum LDH ratio ( $>0.6$ ) and a raised fluid to serum protein ratio ( $>0.5$ ). Treatment should focus on palliation of symptoms and be tailored to the patient's physical condition, treatment options and prognosis. Aspiration alone may be an appropriate treatment in frail patients with a limited life expectancy. Those who present with malignant pleural effusion as the initial manifestation of breast cancer, small cell lung cancer, germ cell tumours or lymphoma should have the fluid aspirated and should be given systemic anti-cancer therapy to try to treat disease in the pleural space. Treatment options for patients with recurrent pleural effusions include pleurodesis, implanted drainage catheters, pleuroctomy and pleuroperitoneal shunt.

## Other common symptoms

Other symptoms that commonly arise from metastatic cancer are: gastrointestinal obstruction, malignant abdominal ascites, hydronephrosis and cancer cachexia.

## Treatment-related toxicities

Whilst most anti-cancer therapies cause some side-effects, most of these can be managed with supportive medicines at home. Some patients will develop severe toxicities and an acute assessment will be needed. Examination of the patient on anti-cancer treatment (p. 128) should consider the type of anti-cancer treatment, duration since the last treatment and other concurrent toxicities. Patients on anti-cancer therapy can deteriorate quickly and prompt assessment and management is required. There may be specific management protocols to help manage treatment-related toxicities and advice should be sought from the patient's cancer centre or acute oncology team.

## Therapeutics in oncology

Anti-cancer therapy may be used with either curative or palliative intent, and this distinction influences the approach to management of individual patients. The goal of treatment should be recorded in the medical notes.

- *Curative therapy* is given with the aim of achieving complete remission. Surgery to remove all macroscopic disease is most frequently the primary curative intervention. However, in some circumstances radiotherapy, systemic anti-cancer therapy or a combination of these may be used with curative, or radical, intent.
- *Adjuvant therapy* is additional therapy given after the primary curative intervention to lower the risk of disease recurrence. Radiotherapy and/or systemic anti-cancer therapy may be given after surgery with the intention of eradicating any micrometastatic disease that remains.
- *Neoadjuvant therapy* is additional therapy given prior to the primary curative intervention. Systemic anti-cancer therapy may be administered prior to planned surgery. The principal aim is to lower the risk of disease recurrence. Any reduction in the volume of disease, or 'downstaging', may also allow less extensive surgery, increase the likelihood of successful debulking and improve subsequent surgical morbidity. Direct evaluation of the surgical specimen allows assessment of the effectiveness of neoadjuvant therapies, guiding subsequent management and lending this approach to translational research.
- *Palliative therapy* is primarily used to treat patients with metastatic disease, or where curative treatment is not possible. The goal is to control cancer, with the aim of improving or maintaining quality of life, treating and preventing symptoms and improving survival. The choice of therapy depends on the clinical situation and a careful evaluation of the risks and benefits of the intervention.

## Surgical treatment

Surgery has a pivotal role in the management of cancer. It is the main curative management of most solid cancers. In early localised cases of colorectal, breast and lung cancer, cure rates are high with surgery. There is evidence that outcome is related to surgical expertise, and most multidisciplinary teams include surgeons experienced in the management of a particular cancer. There are some cancers for which surgery is one of two or more options for primary management, and the role of the MDT is to recommend appropriate treatment for an individual patient. Examples include prostate and transitional cell carcinoma of the bladder, in which radiotherapy and surgery may be equally effective. Specialised surgical, or interventional radiology techniques may also be employed with curative intent. Radiofrequency ablation, microwave ablation or cryotherapy may be used to treat small renal cell carcinomas or hepatocellular carcinomas. Surgery has less of a role in lymphoma, high-grade neuro-endocrine tumours or small cell cancer, where systemic anti-cancer therapy is the main treatment used.

Surgical procedures are often the quickest and most effective way of palliating symptoms in patients with metastatic disease. Examples

include the treatment of faecal incontinence with a defunctioning colostomy; fixation of pathological fractures; decompression of spinal cord compression; and the treatment of fungating skin lesions by 'toilet' surgery. Debulking cytoreductive surgery may improve survival in some cancers, including renal cell carcinoma and ovarian cancer. In very selected cases, such as patients with oligometastatic disease, resection of metastases may improve survival and reduce the need for other therapies.

## Radiotherapy

Radiotherapy (radiation therapy) involves treating the cancer with ionising radiation such as X-rays, gamma rays, electrons or charged atoms. Ionising radiation kills cancer cells by two mechanisms; directly damaging cancer DNA or indirectly by triggering the formation of very reactive molecules (free radicals) that also damage cancer DNA.

Two main types of radiation therapy exist: external beam radiotherapy, and brachytherapy (internal radiotherapy). External beam radiotherapy is most commonly delivered by a linear accelerator, which produces electron or photon beams. As normal tissues can also be damaged by radiotherapy, treatments are planned to ensure maximum exposure of the tumour and minimal exposure of surrounding normal tissues. Improved localisation of the target volume, or tumour, can be achieved by the use of surgical clips at the site of resection and fusion of radiotherapy-planning CT scans with diagnostic MRI or PET-CT scans. Treatment-planning software controls the size and shape of the beam. Intensity modulated radiotherapy (which allows for more homogeneous dose distribution), and volumetric radiotherapy (in which the shape of the radiation beam is designed to closely fit the tumour), have largely replaced conventional methods that use a limited number of square or rectangular beams. Stereotactic radiotherapy is a highly targeted method to deliver focused radiation beams from many different angles which converge on the tumour to deliver high doses precisely. Proton therapy uses a cyclotron to produce beams of high-energy protons, which deposit their radiation dose by a means that allows further sparing of normal tissues.

Brachytherapy, or internal radiation therapy, involves the direct application of a radioactive source onto or into a tumour. This allows the delivery of a high, localised dose of radiation. Brachytherapy is a common treatment for cancers of the prostate, uterus and cervix. Most commonly, an applicator device is used to deliver a radioactive source to the tumour for a set time, typically 10–20 minutes. In other cases, such as in prostate cancer, small radioactive seeds may be permanently placed, releasing radiation slowly over several months. Radioactive liquid treatments, such as <sup>223</sup>radium for bone metastases from prostate cancer or <sup>131</sup>iodine for thyroid cancers are other examples of internal radiation therapy.

Biological differences between normal and tumour tissues are exploited to obtain therapeutic benefit. Fundamental to this is fractionation, which entails delivering the radiation as a number of small doses on a daily basis. This allows normal cells to recover from radiation damage but recovery occurs to a lesser degree in malignant cells. Fractionation regimens vary depending on the tumour being treated, the total radiation dose to be delivered and the intent of treatment. Curative, or radical treatments typically deliver a higher overall dose in 20–35 fractions over 4–7 weeks. For palliative treatments a smaller dose given over 1–10 fractions is usually adequate. Malignant tissues vary widely in their sensitivity to radiotherapy. Germ cell tumours and lymphomas are extremely radiosensitive, and relatively low doses are adequate for cure. However, most other cancers require higher doses. Normal tissue also varies in its radiosensitivity, with the central nervous system, small bowel and lung being among the most sensitive.

The side-effects of radiotherapy depend on the site being treated, the tissue's radiosensitivity and the dose delivered. For example, skin reactions are common with high-dose radical head and neck cancer treatments, or proctitis and cystitis with treatment to the bladder or prostate. These acute reactions typically settle within a few weeks after treatment. Late effects of radiotherapy develop more than 6 weeks after treatment and occur in 5%–10% of patients. Examples include brachial nerve damage and subcutaneous fibrosis after breast cancer treatment. There

is also a risk of inducing new cancer after radiotherapy, which varies depending on the site treated and on whether the patient has had other treatment such as cytotoxic chemotherapy.

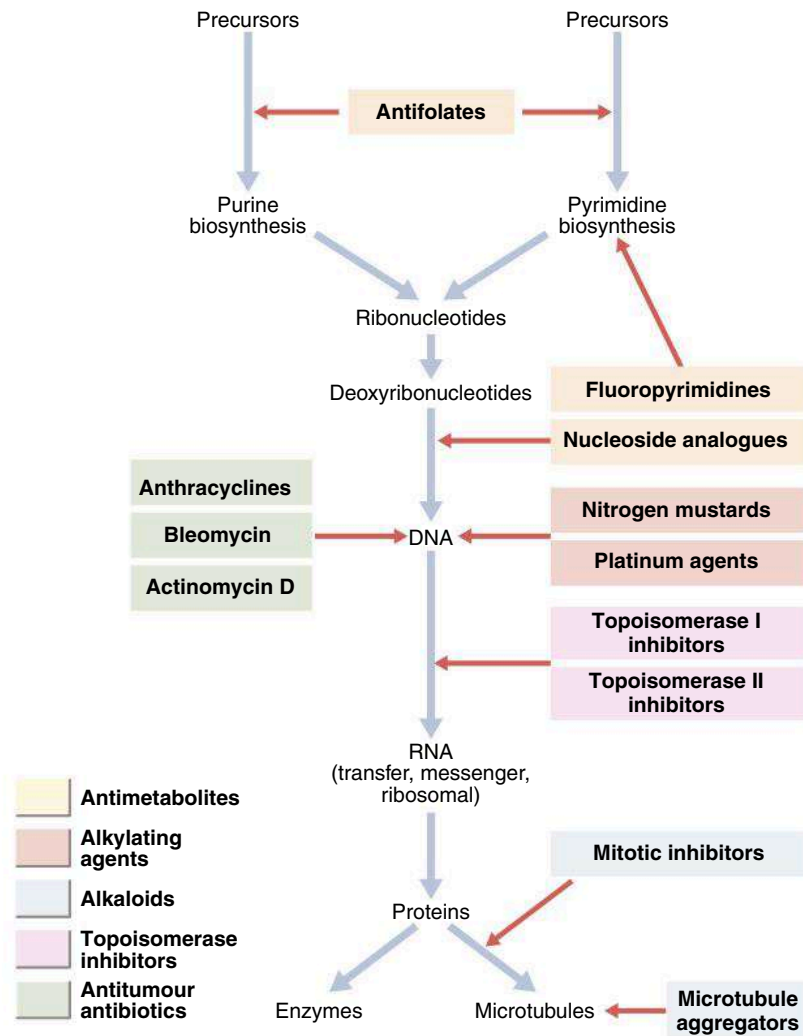

### Systemic anti-cancer therapy

Systemic anti-cancer therapy (SACT) is a collective term to describe the growing number of differing drug therapies used to treat cancer. These drugs reach throughout the body to treat cancer cells wherever they may

be. Increasingly, treatment is tailored to a patient's particular cancer and its molecular profile, allowing more personalised therapy.

### Cytotoxic chemotherapy

Cytotoxic chemotherapy drugs work by interfering with the processes involved in cell division. They are sub-classified by their mode of action (Fig. 7.10). Cytotoxic chemotherapies have their greatest activity in proliferating cells and this provides the rationale for their use in the treatment

	Antifolates	Fluoropyrimidines	Nucleoside analogues	Nitrogen mustards	Platinum agents	Topoisomerase I/II inhibitors	Mitotic inhibitors	Microtubule aggregators	Others – acting on DNA
<b>Mechanism of action</b>	Inhibit dihydrofolate reductase and so purine and pyrimidine synthesis	Inhibit thymidylate synthase and so pyrimidine synthesis	Incorporated into DNA during synthesis, leading to irreparable errors	Form covalent cross-links between DNA molecules by adding an alkyl group to DNA	Form inter-/intra-strand cross-links between DNA molecules, not by adding an alkyl group, so considered alkylating-like agents	Prevent re-ligation of DNA strands by topoisomerase I/II	Bind tubulin, blocking microtubule formation	Stabilise the microtubule polymer preventing its disassembly	1. Intercalate with DNA and inhibit the progression of topoisomerase I 2. Induce DNA strand breaks by oxidative damage 3. Bind to DNA to prevent transcription
<b>Examples</b>	Methotrexate	5-Fluorouracil, capecitabine	Gemcitabine, fludarabine	Cyclophosphamide, ifosfamide	Cisplatin, carboplatin, oxaliplatin	Etoposide (II); topotecan, irinotecan (I)	Vinca alkaloids: vincristine, vinblastine, vinorelbine	Taxanes: paclitaxel, docetaxel	1. Anthracyclines: epirubicin, doxorubicin 2. Bleomycin 3. Actinomycin D

Fig. 7.10 Commonly used cytotoxic chemotherapy agents and their mechanisms of action.

of cancer. However, they are not specific for cancer cells and the side-effects of treatment are largely a result of their antiproliferative actions in normal tissues such as the bone marrow, skin and gut (p. 129). Other organs, such as the heart, kidney and peripheral nervous system, may also be affected by some cytotoxic drugs.

The choice of cytotoxic chemotherapy agent, or combination of treatments, is determined by the cancer type. The dosing schedule is determined by the choice of treatments and recovery of normal tissues, usually the bone marrow. For most common cytotoxic chemotherapy regimens the treatment is administered in cycles. A course of treatment may constitute a pre-defined number of cycles, or may continue indefinitely until evidence of disease progression or until limiting side-effects. Supportive therapy is used to enable patients to tolerate therapy and achieve benefit. Nausea and vomiting are common, but with modern antiemetics, regimens such as the combination of dexamethasone and highly selective 5-hydroxytryptamine (5-HT<sub>3</sub>, serotonin) receptor antagonists such as ondansetron, most patients now receive cytotoxic chemotherapy without any significant problems. Myelosuppression is common to almost all cytotoxics and this not only limits the dose of drug but also can cause life-threatening complications. The risk of neutropenia can be reduced with the use of specific growth factors that accelerate the repopulation of myeloid precursor cells. The most commonly employed is G-CSF, which is widely used in conjunction with cytotoxic chemotherapy regimens that induce a high rate of neutropenia.

## Hormone therapy

Hormones are important cell-signalling molecules and, in some cancers, may be key drivers of tumour growth. Blocking hormonal signalling pathways in these cancers may be a very effective treatment strategy.

Approximately 80% of breast tumours are positive for expression of the oestrogen receptor (ER). Assessment of ER status is now standard in the diagnostic workup of breast cancer. Drugs that reduce oestrogen levels or block the effects of oestrogen on the receptor are widely used in the management of ER-positive breast cancer. Adjuvant hormone therapy may reduce the risk of relapse and death at least as much as cytotoxic chemotherapy and in advanced cases can induce stable disease and remissions that may last months to years, with acceptable toxicity.

Hormonal manipulation may be effective in other cancers. In prostate cancer, hormonal therapy (e.g. luteinising hormone releasing hormone (LHRH) analogues such as goserelin and/or anti-androgens such as bicalutamide) aimed at reducing androgen levels can provide good long-term control of advanced disease. The side-effects of hormone therapies are linked to their hormonal targets.

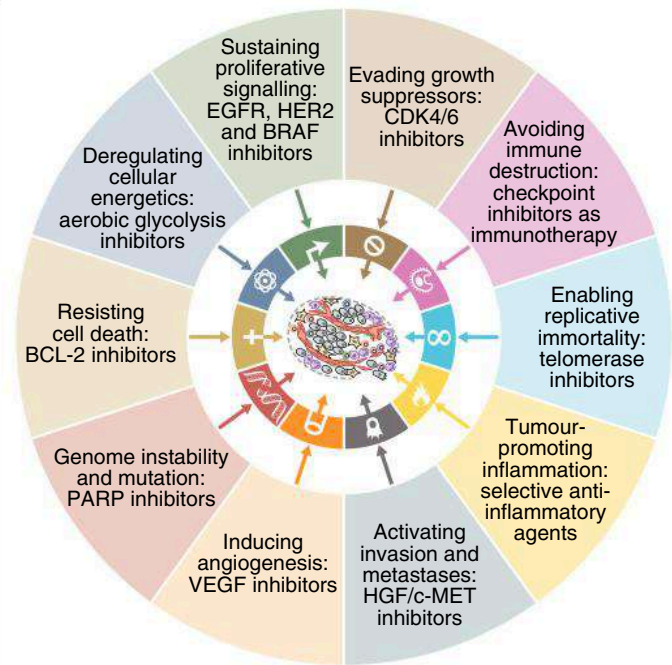

## Targeted therapies

Advances in knowledge about the molecular basis of cancer have resulted in the development of treatments to target specific genes and proteins that are involved in the growth and survival of cancer cells (Fig. 7.11). These signalling pathways may have broad importance to a range of cancer types or be specific to certain cancers. They may not be important in all tumours of the same cancer type, requiring specific molecular testing to predict whether the patient may benefit.

Targeted therapies are broadly divided into two groups: monoclonal antibodies (-mab) and small molecule inhibitors (-ib). The -mab family are typically utilised for targets that are overexpressed on the outside of the cancer cell. The -ib family typically target processes within the cell, such as the cytoplasmic tyrosine kinase, and are designed to be small enough to enter the cell.

A wide range of targeted therapies are now used routinely in oncological practice. Some of these are described below. The side effects of targeted therapies are determined by the molecular pathway being targeted (p. 129).

Epidermal growth factor receptor (EGFR) is an important transmembrane signalling protein. Mutations in the *EGFR* gene lead to overexpression of the EGFR protein or constitutive activation of the cell-signalling

**Fig. 7.11** Examples of targeted anti-cancer therapies and their actions in relation to the Hallmarks of Cancer. (For abbreviations see text.)

pathway, leading to uncontrolled cell division, in several cancer types. Approximately 15% of lung adenocarcinomas have activating mutations of *EGFR*, which may be targeted with drugs such as gefitinib, erlotinib or osimertinib. The latter of these agents has been designed to overcome a particular mutation (i.e. T790M) responsible for 50% of resistance to older EGFR inhibitors. In colorectal cancer drugs such as cetuximab and panitumumab are active in patients where molecular testing does not detect resistance inferred by mutations in the *RAS/RAF* family of genes.

Vascular endothelial growth factor receptor (VEGFR) inhibitors such as sunitinib, pazopanib and cabozantinib have been a pillar of renal cell carcinoma treatment for over a decade. Activation of members of the VEGFR family play an important role in tumour angiogenesis. VEGFR small molecule inhibitors are commonly used in the management of hepatocellular carcinoma and thyroid cancer. Bevacizumab, a monoclonal antibody therapy targeted at VEGF-A, is active in a number of cancers, including ovarian, colorectal and breast.

HER2 is a member of the epidermal growth factor receptor family. Amplification or over-expression of HER2 is found in breast, gastric, pancreatic, lung and some uterine cancers. Approximately 20% of breast cancers are HER2-positive, where it is associated with increased risk of recurrence and poor prognosis. Several agents have been developed to target HER2, including trastuzumab and pertuzumab. The agent trastuzumab emtansine is an antibody-drug conjugate consisting of trastuzumab covalently linked to the cytotoxic chemotherapy agent emtansine which is delivered specifically to the HER2-positive breast cancer cell.

## Immunotherapy

The term immunotherapy encompasses a range of anti-cancer therapies that work by harnessing the immune system to attack cancer cells. Cytokines, such as interferon alpha and interleukin-2, have been used with some success in melanoma and renal cell carcinoma. However, in recent years the development of other immunotherapy treatments has revolutionized the management of several cancer types.

Immune checkpoints are key regulators of the immune system which work to prevent the immune response from attacking normal healthy cells. Cancers may co-opt this mechanism to evade immune destruction. Targeted therapies that inhibit these checkpoint molecules (CTLA4, PD-1) or their ligands (PD-L1) (Fig. 7.12) are now licensed in

**Fig. 7.12** **A** PD-L1 expressed on tumour cells inhibits T-cell activation by binding PD-1. **B** Checkpoint inhibitors block this PD-1–PD-L1 interaction, leading to T-cell activation and tumour cell death. (PD-1 = programmed cell death protein 1; PD-L1 = programmed cell death ligand 1)

the management of many cancers, including melanoma, renal cell carcinoma, lung, bladder, head and neck, and, more broadly, any cancers demonstrating microsatellite instability. Checkpoint inhibitor immunotherapies may be used alone, or in combination with other checkpoint inhibitor immunotherapies, targeted therapies or cytotoxic chemotherapy.

Adoptive cell therapy, also known as cellular immunotherapy, is increasingly being used, particularly in haematological malignancies. Immune cells isolated from either the patient's tumour or bloodstream may be activated and expanded, before being infused back into the patient to attack cancer cells (i.e. tumour infiltrating lymphocyte (TIL) therapy). The immune cells may also be genetically modified to improve the likelihood that they identify the cancer cells (i.e. engineered T-cell (TCR) therapy, chimeric antigen receptor T-cell (CAR-T) therapy). Cancer treatment vaccines are also in development. These aim to boost the immune system's ability to recognise and destroy antigens using a number of different techniques.

Immunotherapy treatment is likely to become more prevalent in the future for many types of cancers and indications. In patients with advanced or metastatic disease a key observation has been the potential for durable treatment responses. For example, average survival for patients with metastatic melanoma has improved from 6–8 months in the pre-immunotherapy era to over 5 years with the use of combination anti-CTLA4 and anti-PD-1 checkpoint inhibitors in clinical trials. However, many patients do not respond and others are affected by potentially life-threatening immune-related adverse events (see above).

## Evaluation of treatment

In advanced or metastatic cancer the evaluation of treatment is an ongoing process and includes assessments of treatment response, toxicity and quality of life. Clinical evaluation alongside radiological imaging

## 7.19 Response evaluation criteria in solid tumours (RECIST)

Response	Criteria
<b>Complete response (CR)</b>	Disappearance of all target lesions
<b>Partial response (PR)</b>	At least a 30% decrease in the sum of the longest diameter (LD) of target lesions, taking as reference the baseline sum LD
<b>Progressive disease (PD)</b>	At least a 20% increase in the sum of the LD of target lesions, taking as reference the smallest sum LD recorded since the treatment started and at least 5 mm increase or the appearance of one or more new lesions
<b>Stable disease (SD)</b>	Neither sufficient shrinkage to qualify for PR nor sufficient increase to qualify for PD, taking as reference the smallest sum LD since the treatment started

or biochemical monitoring are commonly used to determine whether a treatment is being effective. Uniform criteria have been established to measure these, including the response evaluation criteria in solid tumours (RECIST, [Box 7.19](#)) and common toxicity criteria (e.g. common terminology criteria for adverse events (CTCAE)). This allows clinicians to inform patients accurately about the prognosis, effectiveness and toxicity of systemic anti-cancer therapy and empowers patients to take an active role in treatment decisions.

## Late toxicity of therapy

The late toxicities of treatment for cancer are particularly important for patients where multimodality therapy is given with curative intent, where the patient is young and as more patients are living longer. This can cause considerable morbidity; for example, radiotherapy can retard bone and cartilage growth, impair intellect and cognitive function, and cause dysfunction of the hypothalamus, pituitary and thyroid glands. Late consequences of cytotoxic chemotherapy include heart failure due to cardiotoxicity, pulmonary fibrosis, nephrotoxicity and neurotoxicity.

Premature gonadal failure can result from cytotoxic chemotherapy or radiotherapy and leave a patient subfertile. Patients should be made aware of this before treatment is initiated, as it may be possible to store sperm for male patients before treatment starts; this should always be offered, if practical. Egg storage or embryo banking after in vitro fertilisation may be an option for young women. Sterility develops at higher radiotherapy doses but erectile dysfunction is seen in patients receiving high radiotherapy doses to the pelvis, as in prostate cancer. Additional social or psychological support may be required to address these issues. Infertility and pubertal delay are potential late effects of therapy in children, especially boys.

Second malignancies may be induced by cancer treatment and occur at greatest frequency following chemoradiation. Secondary acute leukaemia (mostly AML) can occur 1–2 years after treatment with topoisomerase II inhibitors, or 2–5 years after treatment with alkylating agents. The most common second malignancy within a radiation field is osteosarcoma but others include soft tissue sarcoma and leukaemia.

## Cancer clinical trials

Cancer clinical trials are embedded within routine practice in oncology. Close collaboration with laboratory scientists, active recruitment of cancer patients into clinical trials and robust translational research have led to many new cancer treatments, personalised therapies and a transformation of cancer management over the last 20 years. As many

anti-cancer drugs are expected to have toxicities, which may ultimately limit the deliverable dose, clinical trials in cancer differ from trials of other medicines.

- Phase I cancer clinical trials take treatments of interest from laboratory studies and test them in patients with advanced cancer for whom no other standard anti-cancer treatment exists. Phase I trials assess the safety of a treatment and identify an optimal dose and dosing schedule. Initial doses are very low and each sequential cohort of patients receives a higher dose. Doses are escalated in controlled cohorts of 1–6 patients, according to toxicities, pharmacokinetics and pharmacodynamics, until the maximum tolerated dose is reached.
- Phase II cancer clinical trials treat patients with specific cancers of interest with the trial drug, using the dose established in phase I trials. Phase II trials may be randomised or non-randomised but will recruit enough patients to further assess the safety of the treatment and whether it results in enough anti-cancer activity in a specific cancer to develop the drug further by way of phase III trials.
- Phase III cancer trials are large, multi-centre randomised controlled trials to compare the new treatment of interest with the current established therapy for this indication. Cancer response, toxicity, quality of life and survival data will usually be assessed. Phase III trials may also compare current standard treatment with a different treatment, either looking for improved outcome or improved quality of life with non-inferior outcome. If a treatment is deemed to be safe and effective it will be licensed for clinical use.
- Phase IV trials involve the continuing safety surveillance of a treatment after it receives a licence for clinical use. This can be particularly useful to detect any rare or long-term adverse effects in a much larger population and longer time period than was possible during Phase I–III trials.

## Specific cancers

As cancer management becomes more complex and personalised, and incorporates multi-modality treatment approaches, oncology teams are increasingly subspecialised and work as part of tumour-specific multidisciplinary teams. The diagnosis and management of specific cancers are discussed in more detail elsewhere in the book (Box 7.20). Here we discuss the pathogenesis, clinical features, investigation and management of some common tumours that are not covered elsewhere.

## Breast cancer

Globally, the incidence of breast cancer is second only to that of lung cancer, and the disease represents the leading cause of cancer-related deaths among women. Invasive ductal carcinoma with or without ductal carcinoma in situ (DCIS) is the most common histology, accounting for 70%, whilst invasive lobular carcinoma accounts for most of the remaining cases. DCIS constitutes 20% of breast cancers detected by mammography screening. It is multifocal in one-third of women and has a high risk of becoming invasive (10% at 5 years following excision only). Pure DCIS does not cause lymph node metastases, although these are found in 2% of cases where nodes are examined, owing to undetected invasive cancer. Lobular carcinoma in situ (LCIS) is a predisposing risk factor for developing cancer in either breast (7% at 10 years). The survival for breast cancer by stage is outlined in Box 7.21.

### Pathogenesis

Both genetic and hormonal factors play a role: about 5%–10% of breast cancers are hereditary and occur in patients with mutations of *BRCA1*, *BRCA2*, *AT* or *TP53* genes. Prolonged oestrogen exposure associated with early menarche, late menopause and use of hormone replacement therapy (HRT) has been associated with an increased risk. Other risk

## 7.21 Five-year survival rates for breast cancer by stage

Tumour stage	Stage definition	5-year survival (%)
I	Tumour <2 cm, no lymph nodes	98
II	Tumour 2–5 cm and/or mobile axillary lymph nodes	90
III	Chest wall or skin fixation and/or fixed axillary lymph nodes	72
IV	Metastasis	26

factors include obesity, alcohol intake, nulliparity and late first pregnancy. There is no definite evidence linking use of the contraceptive pill to breast cancer.

### Clinical features

Breast cancer usually presents as a result of mammographic screening or as a palpable mass with nipple discharge in 10% and pain in 7% of patients. Less common presentations include inflammatory carcinoma with diffuse induration of the skin of the breast, and this confers an adverse prognosis. Around 40% of patients will have axillary nodal disease, with likelihood correlating with increasing size of the primary tumour. Distant metastases are infrequently present at diagnosis and the most common sites of spread are bone (70%), lung (60%), liver (55%), pleura (40%), adrenals (35%), skin (30%) and brain (10%–20%).

### Investigations

Following clinical examination, patients should undergo imaging with mammography or ultrasound evaluation, and a biopsy using fine needle aspiration for cytology or core biopsy for histology. Histological assessment should be carried out to assess tumour type and to determine oestrogen and progesterone receptor (ER/PR) status and HER2 status. If distant spread is suspected, CT of the thorax and abdomen and an isotope bone scan are required. Molecular subtyping is being used to classify tumours into four major subtypes: luminal A, luminal B, HER2 type and basal-like

(often called 'triple negative', as these tumours are ER-, PR- and HER2-negative). This may allow more targeted selection of therapies in future.

### Management

Surgery is the mainstay of curative treatment. This can range from a lumpectomy, where only the tumour is removed, to mastectomy, where the whole breast is removed. Breast-conserving surgery is as effective as mastectomy if complete excision with negative margins can be achieved. Lymph node sampling is performed at the time of surgery.

There is significant evidence to support the use of additional therapies to reduce the risk of breast cancer recurrence. Adjuvant radiotherapy is given to reduce the risk of local recurrence. In those patients considered at high risk of recurrence (i.e. tumour of >1 cm, ER-negative disease or the presence of involved axillary lymph nodes) cytotoxic chemotherapy may be offered. In patients with HER2-positive breast cancer adjuvant trastuzumab, a humanised monoclonal antibody to HER2, may be used alongside standard cytotoxic chemotherapy. These treatments are increasingly being used in the neoadjuvant setting, with the aim of achieving a complete pathological response when the cancer is resected, often with a more organ-preserving surgical procedure. In patients with ER-positive tumours adjuvant hormonal therapy may gain additional disease-free and overall survival benefits. Patients at low risk of recurrence (i.e. small, ER-positive disease) may require only adjuvant hormonal therapy. In post-menopausal women adjuvant bisphosphonate therapy may also be used.

The treatment of metastatic breast cancer is complex. Radiotherapy may be used to palliate painful bone metastases. SACT decisions are made with consideration of ER status, HER2 status, the distribution of metastatic disease and previous neo/adjuvant treatment, alongside assessments of performance status (PS) and comorbidities. For example, in a post-menopausal patient with ER-positive, HER2-negative bone-only metastatic disease who is PS 0, hormonal therapy (i.e. an aromatase inhibitor) in combination with a CDK4/6 targeted therapy (i.e. palbociclib, abemaciclib or ribociclib) may be used as first-line treatment. In a similar patient with additional symptomatic liver metastases, cytotoxic chemotherapy may be more appropriate.

## Ovarian cancer

Ovarian cancer is the most common gynaecological tumour in Western countries. Most ovarian cancers are epithelial in origin (90%), and up to 7% of women with ovarian cancer have a positive family history. Patients often present late in ovarian cancer with vague abdominal discomfort, low back pain, bloating, altered bowel habit and weight loss. Occasionally, peritoneal deposits are palpable as an omental 'cake' and nodules in the umbilicus (Sister Mary Joseph nodules).

### Pathogenesis

Genetic and environmental factors play a role. The risk of ovarian cancer is increased in patients with *BRCA1* or *BRCA2* mutations, and Lynch type II families (a subtype of hereditary non-polyposis colon cancer, HNPCC) can have ovarian, endometrial, colorectal and gastric tumours due to mutations of mismatch repair enzymes. Advanced age, nulliparity, ovarian stimulation and European descent all increase the risk of ovarian cancer, while suppressed ovulation appears to protect, so pregnancy, prolonged breastfeeding and the contraceptive pill have all been shown to reduce the risk of ovarian cancer.

### Investigations

Initial workup for patients with suspected ovarian cancer includes imaging in the form of ultrasound and CT. Serum levels of the tumour marker CA-125 are often measured. Surgery plays a key role in the diagnosis, staging and treatment of ovarian cancer, and in early cases, palpation of viscera, peritoneal washings and biopsies are generally performed to define disease extent.

### Management

In early disease, surgery followed by adjuvant cytotoxic chemotherapy with carboplatin, or carboplatin plus paclitaxel, is the treatment of choice.

Surgery should include removal of the tumour along with total abdominal hysterectomy, bilateral salpingo-oophorectomy, and omentectomy. Even in advanced disease, surgery is undertaken to maximally debulk the tumour and is followed by cytotoxic chemotherapy, typically using carboplatin and paclitaxel. Bevacizumab, a targeted therapy against VEGFR, is indicated for patients with high-grade tumours that are suboptimally debulked or those with a more aggressive biological pattern. Subsequent treatment decisions are made with consideration of response to first-line cytotoxic chemotherapy and germline BRCA mutation status. Options include further platinum/paclitaxel combination, liposomal doxorubicin or targeted therapy against poly-ADP ribose polymerase (PARP, e.g. olaparib, niraparib or rucaparib).

The serum tumour marker CA-125 and clinical examination may be used to monitor treatment response in ovarian cancer, with CT imaging for those with suspected progressive disease.

## Endometrial cancer

Endometrial cancer accounts for 4% of all female malignancies, producing a 1 in 73 lifetime risk. The majority of patients are post-menopausal, with a peak incidence at 50–60 years of age. Mortality from endometrial cancer is currently falling. The most common presentation is with post-menopausal bleeding, which often results in detection of the disease before distant spread has occurred.

### Pathogenesis

Oestrogen plays an important role in the pathogenesis of endometrial cancer, and factors that increase the duration of oestrogen exposure, such as nulliparity, early menarche, late menopause and unopposed HRT, increase the risk. Endometrial cancer is 10 times more common in obese women and this is thought to be due to elevated levels of oestrogens.

### Investigations

The diagnosis is confirmed by endometrial biopsy.

### Management

Surgery is the treatment of choice and is used for staging. A hysterectomy and bilateral salpingo-oophorectomy are performed with peritoneal cytology and, in some cases, lymph node dissection. Where the tumour extends beyond the inner 50% of the myometrium or involves the cervix and local lymph nodes, or there is lymphovascular space invasion, adjuvant pelvic radiotherapy is recommended. Cytotoxic chemotherapy is used as adjuvant therapy, and hormonal therapy and cytotoxic chemotherapy are used to palliate symptoms in recurrent disease.

## Cervical cancer

Cervical cancer is the fourth most common cancer in women and the leading cause of death from gynaecological cancer worldwide. The incidence is decreasing in high-income industrialised countries but continues to rise in low- and middle-income nations. The most common presentation in the UK is with an abnormal smear test, but with locally advanced disease the presentation is with vaginal bleeding, discomfort, discharge or symptoms attributable to involvement of adjacent structures, such as bladder, or rectal or pelvic wall. Occasionally, patients present with distant metastases to bone and lung.

### Pathogenesis

Almost all cases of cervical cancer are linked to high-risk human papillomaviruses (HPV), transmitted through sexual contact. This has underpinned the introduction of programmes to immunise adolescents against HPV in an effort to prevent up to 90% of cervical cancer.

### Investigations

Diagnosis is made by smear or cone biopsy. Further examination may require cystoscopy and flexible sigmoidoscopy if there are symptoms referable to the bladder, colon or rectum. In contrast to other gynaecological

malignancies, cervical cancer is a clinically staged disease, although MRI is often used to characterise the primary tumour. CT of the chest, abdomen and pelvis is performed to look for metastases in the lungs, liver and lymph nodes, and to exclude hydronephrosis and hydroureter.

### Management

This depends on the stage of disease. Pre-malignant disease can be treated with laser ablation or diathermy, whereas in microinvasive disease a large loop excision of the transformation zone (LLETZ) or a simple hysterectomy is employed. Invasive but localised disease requires radical surgery, while cytotoxic chemotherapy and radiotherapy, including brachytherapy, may be given as primary treatment, especially in patients with adverse prognostic features such as bulky or locally advanced disease, or lymph node or parametrium invasion. In metastatic disease, platinum-based cytotoxic chemotherapy may be beneficial in improving symptoms but does not increase survival significantly.

## Head and neck tumours

Head and neck cancers are typically squamous tumours that arise in the nasopharynx, hypopharynx and larynx. They are most common in older adult males but oropharyngeal cancers now occur with increasing frequency in a younger cohort of patients, including in women. The rising incidence of oropharyngeal cancers, especially in high-income countries, is thought to be secondary to HPV infection. Presentation depends on the location of the primary tumour and the extent of disease. For example, early laryngeal cancers may present with hoarseness, while more extensive local disease may present with pain due to invasion of local structures or with a lump in the neck. Patients who present late often have pulmonary symptoms, as this is the most common site of distant metastases (Box 7.22).

### Pathogenesis

The tumours are strongly associated with a history of smoking and excess alcohol intake, but other recognised risk factors include Epstein-Barr virus for nasopharyngeal cancer and HPV infection for oropharyngeal tumours.

### Investigations

Careful inspection of the primary site is required as part of the staging process, and most patients will require endoscopic evaluation and examination under anaesthesia. Tissue biopsies should be taken from the most accessible site. CT of the primary site and the thorax is the investigation of choice for visualising the tumour, while MRI may be useful in certain cases.

#### 7.22 Common presenting features by location in head and neck cancer

##### Hypopharynx

- Dysphagia
- Odynophagia
- Referred otalgia
- Enlarged lymph nodes

##### Mouth and tongue

- Non-healing ulcers
- Ipsilateral otalgia

##### Nasal cavity and sinuses

- Discharge (bloody) or obstruction

##### Nasopharynx

- Nasal discharge or obstruction
- Conduction deafness
- Atypical facial pain
- Diplopia
- Hoarse voice
- Horner syndrome

##### Oropharynx

- Dysphagia
- Pain
- Otolgia

##### Salivary gland

- Painless swelling
- Facial nerve palsy

## Management

In general, the majority of patients with early or locally advanced disease are treated with curative intent. In localised disease where there is no involvement of the lymph nodes, long-term remission can be achieved in up to 90% of patients with surgery or radiotherapy. The choice of surgery versus radiotherapy often depends on patient preference, as surgical treatment can be mutilating with an adverse cosmetic outcome. Patients with lymph node involvement are treated with a combination of surgery and radiotherapy (often with a radiosensitising agent such as cisplatin or cetuximab), and this produces long-term remission in approximately 60%–70% of patients. Recurrent or metastatic tumours may be palliated with further surgery or radiotherapy to aid local control, or systemic cytotoxic chemotherapy or immunotherapy may be used. Second malignancies are common (3% per year) following successful treatment for primary disease, and all patients should be encouraged to give up smoking and drinking alcohol to lower their risk.

## Survivorship

Advances in cancer prevention, diagnosis and treatment mean that more people are surviving cancer. Cancer survival has doubled in the last 40 years in the UK. There are an estimated 2 million people living with, or beyond, cancer in the UK today and 50% of those diagnosed with cancer will survive their disease for 10 years or more. Cancer survivorship has at least two common meanings:

- completing treatment for cancer and having no signs of cancer after finishing treatment
- living with, through and beyond cancer, thus including people who receive curative treatment and people who receive intermittent anti-cancer treatment to control their cancer over a longer time.

Many people feel that life is never the same after a cancer diagnosis. There are often long-lasting physical, social and emotional consequences of both cancer and its treatment. These start at diagnosis and last through first treatment (acute survivorship), continue through and beyond cancer treatments (extended survivorship) and can be long-lasting, even when risk of cancer recurrence is low (permanent survivorship). An increasing awareness of survivorship, the impact of a cancer diagnosis and its wide-ranging effects on patients has highlighted the need for holistic and patient-centred care, support and services throughout and after cancer treatment.

## Multiple Choice Questions

7.1. A 54-year-old woman presents to the emergency department with fevers and a sore throat. She has recently been diagnosed with left-sided breast cancer and associated axillary lymph node disease. Twelve days ago she received her first cycle of neoadjuvant cytotoxic chemotherapy (5-fluorouracil, epirubicin and cyclophosphamide). On clinical examination her temperature is 38.3°C, she appears dehydrated and there is evidence of oral candidiasis. An intravenous catheter is placed and bloods, including blood cultures, taken. What is the most appropriate next step in this patient's care?

- A. Start oral fluconazole
- B. Await blood test results to inform further management
- C. Start intravenous fluids
- D. Perform a chest X-ray, collect a urine sample and throat swab to complete the infection screen
- E. Start high-dose broad-spectrum intravenous antibiotic therapy immediately

Answer: E.

The clinical features here are of fever in a patient at high risk of neutropenia. This is an oncological emergency. Patients are at risk of neutropenia at any point during their systemic anti-cancer therapy treatment cycle, with the highest risk typically 10–14 days after a treatment. In patients with potential neutropenic sepsis high-dose broad spectrum intravenous antibiotics should be commenced, ideally within 1 hour of admission, without awaiting test results. In this patient fluconazole (A) for oral candidiasis, intravenous fluids (C) and further tests (D) are also appropriate, but should not delay the first dose of antibiotic therapy. Test results may later inform changes to antimicrobial therapy and its duration.

7.2. A 61-year-old man recently diagnosed with colon cancer and associated liver and lung metastases is seen in the oncology clinic. He is keen to talk about treatment for his cancer. His ECOG performance status is 1 and he has no significant comorbidities. He has some mild symptoms of abdominal discomfort and has lost 5 kg in weight. His routine bloods demonstrate anaemia (Hb105 g/L) and mild elevations in his liver enzymes. A biopsy of his tumour has shown a moderately differentiated adenocarcinoma which is KRAS/NRAS wildtype and *BRAF* mutant. What is the most appropriate treatment option for this patient?

- A. Cytotoxic chemotherapy (5-fluorouracil, folinic acid and oxaliplatin) alone
- B. Surgery to all cancer sites
- C. Cytotoxic chemotherapy (5-fluorouracil, folinic acid and oxaliplatin) with an EGFR inhibitor (cetuximab)
- D. Cytotoxic chemotherapy (5-fluorouracil, folinic acid and oxaliplatin) with a BRAF inhibitor (dabrafenib)
- E. Refer to palliative care

Answer: A.

This man wishes to pursue anti-cancer therapy and, from the information provided, appears fit to do so. In patients with metastatic disease systemic anti-cancer therapies are most often used, unless there is a need to palliate a specific symptom. Cytotoxic chemotherapy would be an appropriate option here. As the tumour is *BRAF* mutant he is unlikely to respond to an EGFR inhibitor such as cetuximab. BRAF inhibitors such as dabrafenib are not used in colon cancer regardless of the mutational status.

7.3. A 59-year-old woman is seen in the emergency department with a 2-day history of severe diarrhoea. She has had 10 loose stools today, the most recent of which have been bloody and associated with crampy abdominal pain. Her past medical history includes metastatic melanoma and she had her fourth cycle of ipilimumab and nivolumab therapy 20 days ago. At the time of her treatment she was constipated and the outpatient systemic anti-cancer therapy unit doctor prescribed her a macrogol laxative. She notes that the evening prior to the diarrhoea starting she had reheated some leftover rice for her supper. What is the most important likely diagnosis?

- A. *Bacillus cereus*-associated food poisoning
- B. Overflow diarrhoea
- C. Laxative overuse
- D. Immunotherapy-related colitis
- E. *Clostridioides difficile* infection

Answer: D.

Immune-related adverse events should be considered in all patients who present acutely unwell following immunotherapy treatments for cancer. Although the other options are on the differential diagnosis list, severe IRAEs are oncological emergencies and prompt recognition and management are vital. This is a grade 3 colitis and should be treated with IV methylprednisolone in the first instance. Investigations such as bloods, stool sample, radiological imaging and flexible sigmoidoscopy or colonoscopy are also appropriate.

7.4. A 58-year-old man is seen in clinic with a diagnosis of metastatic lung cancer. He is coping well at home, where he lives alone. However, he has taken early retirement as a brick-layer as he feels unable to work due to increasing fatigue. He awakes early each morning and goes to the shops to collect his newspaper, but has taken to napping for an hour in the afternoon. What is this man's ECOG performance status?

- A. 0
- B. 1
- C. 2
- D. 3
- E. 4

Answer: B.

This man is ambulatory and capable of self-care, but unable to undertake strenuous activity. He is up for more than 50% of waking hours. Performance status is a key assessment tool in patients with cancer.

7.5. You have been asked to see a 70-year-old man on a medical ward. He was admitted 2 weeks ago following a fall. On admission he had abnormal liver function tests and an elevated CRP. He has been treated for a urinary tract infection. A CT scan has demonstrated multiple liver, lung and bone metastases, but no obvious primary cancer. The ward nurses tell you he remains mildly confused at times, sleeps for most of the day and does not wish to engage with physiotherapy. What is the most appropriate management for this man?

- A. Refer to the Hepatobiliary Pancreatic Cancer Multidisciplinary Team
- B. Ultrasound-guided liver biopsy
- C. Colonoscopy
- D. Palliative care
- E. Cytotoxic chemotherapy

Answer: D.

This man has a new diagnosis of metastatic cancer of undefined primary origin (MUO). His ECOG performance status (3), requirement for hospital admission, multi-organ metastatic disease, end-organ dysfunction and raised inflammatory markers are poor prognostic features. Further investigations may not be warranted and honest conversations about the likely diagnosis, palliative care and end-of-life care, taking into account the patient's wishes are often preferable.

7.6. A 56-year-old woman is seen in oncology clinic following surgery to remove a localised clear cell renal cell carcinoma. She is eligible for a phase III clinical trial comparing adjuvant immunotherapy to the current clinical standard of observation. Patients will be randomised to receive either the immunotherapy treatment or a placebo every 4 weeks for 1 year. Neither the patient nor the investigator will know what treatment she is receiving. Which of the following statements regarding randomised controlled trials (RCTs) is true?

- A. Patients may choose which treatment they receive
- B. RCTs are always 'double blinded'

- C. RCTs are considered to be the 'gold standard' for determining efficacy and safety in clinical research
- D. RCTs always have a control arm that uses placebo
- E. RCTs always equally divide patients between each treatment arm

Answer: C.

Phase III RCTs are often used to determine whether a treatment should be licensed for clinical use. Patients are randomised to each arm, sometimes with stratification to ensure equal allocation of patient subgroups. RCTs may be double-blinded, as is the case here, single-blinded or 'open-label'. The control arm should be the current clinical standard treatment. In this example a placebo is used in the place of observation only to ensure blinding and avoid potential bias of results. Patients may be divided in alternative ratios. This is sometimes the case when earlier studies suggest large differences between the investigational and current treatment.

*Insets (SVC obstruction, wasting in the hand, pleural effusion, ascites, amputation) From Forbes CD, Jackson WF. Color atlas and text of clinical medicine, 3rd edn. Edinburgh: Mosby; 2002. (CRPS = chronic regional pain syndrome; SVC = superior vena cava)*

Clinical evaluation and management in a patient with chronic pain or in the palliative care setting

character and radiation of pain

Take careful history, recording

Conduct psychosocial assessment

Assess mood and screen for depression

Conduct general examination

Check gait and whether using a walking aid

Assess pinprick, fine touch and heat/cold sensation

Conduct neurological examination

Educate patient on nature of pain and promote self-management

Formulate management plan with patient and set goals

Optimise medication

Consider psychological therapies and mindfulness

Increase physical activity

Consider yoga, pilates or tai chi

Consider TENS and acupuncture

Consider nerve block or ablation

(TENS = transcutaneous electrical nerve stimulation)

## Pain

Pain is defined as 'an unpleasant sensory and emotional experience associated with actual or potential tissue damage or described in terms of such damage'. It is one of the most common symptoms for which people seek health-care advice. Our understanding of the mechanisms of pain has evolved considerably from Hippocrates' suggestion in 450 BC that pain arose as a result of an imbalance in vital fluids. We now know that pain is a complex symptom that is influenced and modified by many social, cultural and emotional factors, as illustrated in [Figure 8.1](#). The sensation of acute pain that occurs in response to inflammation or tissue damage plays an important role in protection from further injury. Chronic pain serves no useful function but results in significant distress and suffering for the patient affected, as well as having a wider societal impact.

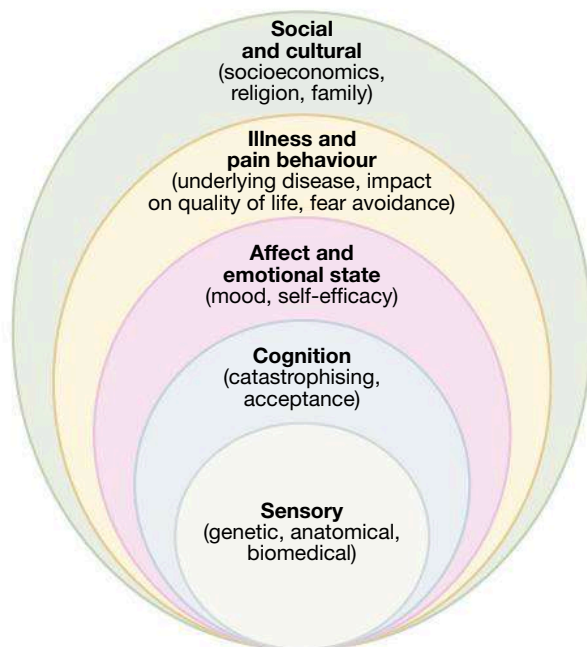

## Functional anatomy and physiology

The functional anatomy of the somatosensory system is shown in [Figures 28.3](#) and [28.6](#). Here, discussion will focus on the mechanisms and mediators that are involved in pain processing.

## Peripheral nerves

Peripheral nerves contain several types of neuron. These can be classified into two groups, depending on whether or not they are surrounded by a myelin sheath. Myelinated neurons have a fast conduction velocity and are responsible for transmission of various sensory signals, such as proprioception, light touch, heat and cold, and the detection of localised pains, such as pin-prick. Unmyelinated fibres have a much slower conduction velocity and are responsible for transmitting diffuse and poorly localised pain, as well as other sensations ([Box 8.1](#)).

Sensory neurons (also known as primary afferent neurons) connect the spinal cord to the periphery and supply a defined territory or a dermatome, which can be used to identify the position of a nerve lesion

**Fig. 8.1** The biopsychosocial model of pain. The perception of pain as a symptom is dependent not only on sensory inputs but also on the individual's cognitive reaction to the pain, their emotional state, their underlying disease and their social and cultural background.

## 8.1 Types of nerve fibre

Fibre type	Diameter ( $\mu\text{m}$ )	Conduction velocity ( $\text{ms}^{-1}$ )	Function
<b>Large myelinated</b>			
A $\alpha$	12–20	70–120	Proprioception Motor to muscle fibres
A $\beta$	5–12	30–70	Light touch, pressure
A–	3–6	15–30	Motor to muscle spindles
<b>Small myelinated</b>			
A	2–5	12–30	Well-localised pain Thermal sensation
B	<3	3–15	Pre-ganglionic autonomic
<b>Unmyelinated</b>			
C	0.4–1.3	0.5–3	Diffuse pain Poorly localised thermal sensation Post-ganglionic autonomic

(see [Fig. 28.10](#)). In healthy individuals, dermatomes have distinct borders, but in pathological pain syndromes these may become blurred as the result of neuronal plasticity, which means that pain may be felt in an area adjacent to that supplied by a specific nerve root. Autonomic neurons also contain pain fibres and are responsible for transmitting visceral sensations, such as colic. In general, visceral pain is diffuse and less well localised than pain transmitted by sensory neurons.

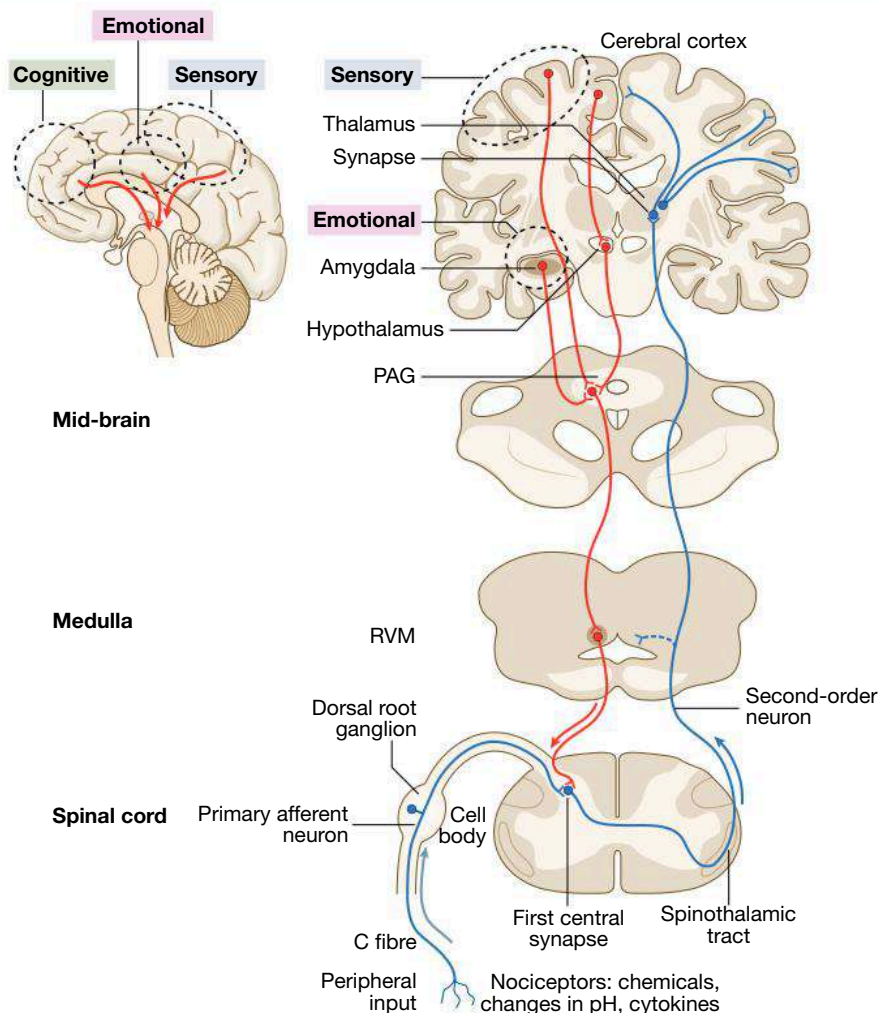

Anatomical features of the afferent pain pathway are illustrated in [Figure 8.2](#). Pain signals are transmitted from the periphery to the spinal cord by sensory neurons. These have the following components:

- *A cell body*, containing the nucleus, which is situated in the dorsal root ganglion close to the spinal cord. The cell body is essential for survival of the neuron, production of neurotransmitters and neuronal function.
- *The nerve fibre (axon) and peripheral nerve endings*, which are located in the periphery and contain a range of receptors in the neuronal membrane.
- *Specialised receptors* in the periphery, consisting of bare nerve endings known as nociceptors or pain receptors, which are activated by various mediators. They are situated mainly in the epidermis.
- *The central termination*, which travels to the dorsal horn of the spinal cord to form the first central synapse with neurons that transmit pain sensation to the brain.

When a noxious stimulus is encountered, activation of nociceptors leads to generation of an action potential, which travels upwards to the dorsal root ganglion and also stimulates the release of neurotransmitters that have secondary effects on surrounding neurons.

## Spinal cord

Sensory neurons, through their central termination, synapse with second-order neurons in the dorsal horn of the spinal cord. There is considerable modulation of pain messages at this site, both from local neurons within the spinal cord and from neurons that descend from the brain, as depicted in [Figure 28.11](#). Several neurotransmitters are involved in pain processing at this level and these are summarised in [Box 8.2](#). They include amino acids, such as glycine and  $\gamma$ -aminobutyric acid (GABA), which are inhibitory, and glutamate, which is excitatory; neuropeptides, such as substance P and calcitonin gene-related peptide (CGRP); and endorphins. Whether or not they increase or decrease pain perception depends on the connectivity of the neurons on which they act.

**Fig. 8.2 Ascending and descending pain pathways.** Ascending pathways are shown in blue and descending in red. Pain signals are detected in the periphery by nociceptors, which are activated by chemicals, changes in pH and cytokines. The signal is transmitted by the primary afferent neuron to the spinal cord, where there is a synapse with a second-order neuron, which transmits the signal onwards to the thalamus. Thereafter, the pain signal is transmitted to the cerebral cortex. The intensity of pain signals is subject to extensive modulation at several levels within the nervous system. Cognitive influences derived from the frontal lobe, coupled with sensory influences from cortex and emotional influences from the amygdala, affect pain perception in the mid-brain around the periaqueductal grey matter (PAG) and the rostroventrolateral medulla (RVM) in the medulla. These structures form part of the descending modulatory systems, which, under normal circumstances, inhibit pain perception. In some chronic pain states, however, dysfunction of the descending pathways can occur, increasing pain.

## Central processing of pain

The signals transmitted by second-order neurons in the spinal cord are relayed to the sensory cortex by third-order neurons, which synapse with second-order neurons in the thalamus. At this site, perception of pain is influenced by interactions between a range of structures in the brain, where sensory, cognitive and emotional aspects are integrated. This is termed the pain neuromatrix (see Fig. 8.2). Signals within the neuromatrix are multidirectional in nature, involving modulation of incoming messages by the cerebral cortex (top-down regulation), as well as a complex network of connections between other subcortical structures. Under normal conditions, there is a degree of descending inhibition from the brainstem that reduces input from peripheral stimuli.

It is thought that chronic widespread pain (CWP) and opioid-induced hyperalgesia may result, at least in part, from abnormalities in central processing of pain signals. It has also been suggested that variations in the levels of descending inhibition between individuals may make some people more vulnerable than others to developing chronic pain. Over recent years, there has been increasing interest in the role that glial cells (see Fig. 28.1) play in pain processing. Both astrocytes and microglial cells can become activated in chronic pain states and release pro-inflammatory cytokines, as well as altering re-uptake of excitatory neurotransmitters

such as glutamate, which can influence pain perception considerably. As our understanding of these processes improves, there is increasing potential to develop novel therapies targeted at these mediators, with some early clinical studies in neuropathic pain (pain related to nerve injury or disease, with characteristic neurobiological changes).

## Sensitisation

Sensitisation is one of the key features of pain processing. It refers to the fact that both peripheral and central nervous systems adapt rapidly to the presence of pain, especially in response to tissue damage. This adaptive process is called neuronal plasticity. In some situations, neuronal plasticity can lead to prolonged changes in the pathways that are involved in detecting and processing nociceptive stimuli, resulting in chronic pain syndromes. The specific changes in key neurotransmitters and receptors differ between chronic pain states, with implications for the efficacy of treatments. For example, mu opioid receptors are down-regulated in neuropathic pain, potentially leading to limited opioid responsiveness.

### Peripheral sensitisation

Peripheral sensitisation can occur in association with a variety of clinical conditions, including sepsis, cancer, inflammatory disease, injury,

## 8.2 Neurotransmitters and receptors involved in pain processing in the spinal cord

Neurotransmitter	Receptor(s)	Receptor type	Comments*	
<b>Amino acids</b> Glutamate	AMPA	Ion channel	Excitatory; permeable to cations: can be Ca <sup>2+</sup> , Na <sup>+</sup> or K <sup>+</sup> , depending on subunit structure	
	NMDA	Ion channel	Excitatory; blocked by Mg <sup>2+</sup> in the resting state; block can be altered if membrane potential changes; permeable to Ca <sup>2+</sup> , Na <sup>+</sup> and K <sup>+</sup>	
	Kainate	Ion channel	Post synaptic – excitatory	
	Gp I	GPCR	Pre-synaptic – inhibitory through GABA release; permeable to Na <sup>+</sup> and K <sup>+</sup>	
	Gp II	GPCR	Activates a range of signalling pathways; long-term effects on synaptic excitability	
	Gp III	GPCR	Probably inhibitory; can decrease cAMP production; pre-synaptic; decreases glutamate release	
Glycine	GlyR	Ion channel	Mainly inhibitory; permeable to Cl <sup>-</sup> ; blocked by caffeine	
GABA	GABA <sub>A</sub>	Ion channel	Mainly inhibitory in spinal cord; permeable to Cl <sup>-</sup> ; indirectly modulated by benzodiazepines (increased ion channel opening); not specifically involved in nociception, generally depressant effect on spinal cord activity	
	GABA <sub>B</sub>	GPCR	Predominantly inhibitory; activated by baclofen	
<b>Neuropeptides</b>	Substance P	Neurokinin receptors	GPCR	Mainly excitatory; increased in inflammation, decreased in neuropathic pain
	Cholecystokinin	CCKRs1–8	GPCR	Excitatory; clinical trials of antagonists in progress
	Calcitonin gene-related peptide	CALCRL	GPCR	Excitatory; slows degradation of substance P; implicated in migraine
<b>Opioids</b>	Dynorphin	DOP	GPCR	Excitatory?; may be pro-nociceptive
	β-endorphin	MOP	GPCR	Inhibitory
	Nociceptin	NOP	GPCR	Inhibitory; also expressed by immune cells

(AMPA = α-amino 3-hydroxy, 5-methyl, 4-isoxazole propionic acid; CALCRL = calcitonin receptor-like receptor; cAMP = cyclic adenosine monophosphate; CCKR = cholecystokinin receptor; DOP = delta opioid receptor; GABA = γ-aminobutyric acid; Gp = group; GPCR=G-protein-coupled receptor; MOP = mu opioid receptor; NMDA = N-methyl-D-aspartate; NOP = nociceptin/orphan receptor)  
\*Excitatory = increased pain; inhibitory = reduced pain.

surgery and obesity. The final common pathway by which sensitisation takes place in all of these conditions is inflammation. Inflammation is accompanied by increased capillary permeability and tissue oedema with the release of a diverse range of mediators, including bradykinin, hydrogen ions, prostaglandins and adenosine, which bind to receptors and ion channels on nociceptors of primary afferent neurons (Fig. 8.3). The signalling pathways activated by these mediators generate action potentials, which are transmitted by sensory neurons to the spinal cord. If these pain-provoking stimuli persist, the activation threshold of sensory neurons is reduced, resulting in an increased transmission of pain signals to the spinal cord.

### Central sensitisation

Sensitisation may also take place at the level of the spinal cord in response to a sustained painful stimulus. It can occur acutely and rapidly, such as immediately after surgery, or may progress to chronic changes, such as chronic infection, cancer, repeated surgery or multiple traumatic episodes. Glutamate, acting via the N-methyl-D-aspartate (NMDA) receptor complex, plays a key role in central sensitisation (Fig. 8.4). In response to a sustained peripheral painful stimulus, increased amounts of glutamate are released in the spinal cord, overcoming the inhibitory action of magnesium ions and resulting in activation of the NMDA receptor. This initiates a cascade of intracellular signalling events that lead to prolonged modifications of somatosensory processing, with amplification of pain responses within the spinal cord and continued neuronal firing, even after the noxious stimulus has stopped. This phenomenon is termed 'after-discharge'. In neuropathic pain, prolonged activation of the NMDA pathway results in a decrease in the number of inhibitory interneurons, which further potentiates pain.

### Genetic determinants of pain perception

There are marked ethnic and individual variations in how people respond to painful stimuli and studies in twins have estimated that the heritability of CWP ranges between 30% and 50%. In the general population, the individual variants in response to pain and perception of pain are most likely due to a complex interaction between genetic and environmental influences. Few variants have been identified with robust evidence of association with CWP. Several rare syndromes have been described, however, in which insensitivity to pain or heightened pain responses occur as the result of a single gene disorder, as summarised in Box 8.3. Most are due to mutations affecting ion channels that play a key role in neurotransmission (see Fig. 8.3), but other causes include mutations in the *NTKR1* gene, which encodes the receptor for nerve growth factor, and mutations in the *PDRM12* transcription factor, which is involved in neuron development.

### Investigations

Pain can be a presenting feature of a wide range of disorders and the first step in evaluation of a patient with pain should be to perform whatever investigations are required to define the underlying cause of the pain, unless this is already known. However, with most chronic pain syndromes, such as fibromyalgia, complex regional pain syndrome and CWP, investigations are negative and the diagnosis is made on the basis of clinical history and exclusion of other causes. Specific investigations that are useful in the assessment of selected patients with chronic pain are discussed below.

**Fig. 8.3 Mechanisms of peripheral sensitisation.** **A** Sensory nerve terminating with nociceptor in skin. **B** Peripheral nociceptors express various receptors and ion channels that act as mediators of pain. They include sodium channels implicated in congenital pain syndromes; the purinergic 2X (P2X) and purinergic 2Y (P2Y) receptor for adenosine triphosphate (ATP); members of the transient receptor potential (TRP) superfamily of ion channel receptors, which detect changes in osmolality and temperature; acid-sensing ion channel (ASIC) receptors, which detect hydrogen ions; G-protein-coupled receptors, which detect bradykinin (BK), prostaglandins and ATP; sodium-potassium hyperpolarization-activated cyclic nucleotide-gated channels (HCN2), and voltage gated potassium channels (Kv) and the neurotrophic tyrosine kinase 1 (NTRK1) receptor, which detects nerve growth factor (NGF). **C** Activation of these receptors by ligands, hydrogen ion [H<sup>+</sup>] and high temperature (> 42°C) amplifies action potentials, which increase pain signals and cause peripheral sensitisation. (EP = E-prostanoid receptor) Adapted from Bennett DL, Woods CG. Painful and painless channelopathies. *The Lancet Neurol* 2014; 13:587–599; reproduced with permission from Elsevier.

**Fig. 8.4 Mechanisms of central sensitisation.** Post-synaptic activation of the *N*-methyl-D-aspartate (NMDA) receptor requires the amino acids glycine and glutamate, which bind to the NR1 and NR2 subunits, respectively; these amplify pain signals at the level of the spinal cord. In contrast, magnesium ions block receptor activation.

## Magnetic resonance imaging

Magnetic resonance imaging (MRI) can be helpful in the assessment of an underlying cause in patients with focal pain that follows a nerve root or peripheral nerve distribution. Imaging is seldom helpful in individuals with CWP.

## Blood tests

Blood tests are not generally helpful in the diagnosis of chronic pain, except in patients with peripheral neuropathy; in this case, a number of blood tests may be required to investigate the underlying causes of the neuropathy. Full details are provided in [Box 28.85](#). Genetic testing may

### 8.3 Genetic regulators of pain perception

Gene (protein)	Mutation (inheritance)	Protein function	Phenotypes
<i>SCN9A</i> (Na <sub>v</sub> 1.7)	LoF (AR)	Ion channel	Absent pain, hypohydrosis, anosmia
<i>SCN9A</i> (Na <sub>v</sub> 1.7)	GoF (AD)	Ion channel	Erythromelalgia, paroxysmal pain, burning pain, autonomic dysfunction
<i>SCN11A</i> (Na <sub>v</sub> 1.9)	GoF (AD)	Ion channel	Absent pain, hyperhydrosis, muscular weakness, gut dysmotility
<i>SCN10A</i> (Na <sub>v</sub> 1.8)	GoF (AD)	Ion channel	Burning pain, autonomic dysfunction
<i>TRPA1</i> (TRPA1)	GoF (AD)	Ion channel	Absent pain
<i>PDRM12</i> (PDRM12)	LoF (AR)	Transcription factor; neuron development	Absent pain
<i>NTRK1</i> (high-affinity NGF receptor)	LoF (AR)	Tyrosine kinase; promotes neuron development	Absent pain; anhydrosis, mental retardation, increased cancer risk

(AD = autosomal dominant; AR = autosomal recessive; GoF = gain of function; LoF = loss of function; NGF = nerve growth factor)

be of value in patients with clinical features that point to an inherited disorder of pain processing (see [Box 8.3](#)).

#### Quantitative sensory testing

Quantitative sensory testing can be helpful in the detailed assessment of patients with chronic pain. A simple set of tools can be used in the clinical setting ([Fig. 8.5](#)). Lightly touching the skin with a brush, swab or cotton-wool ball can be used to test for abnormalities of fine touch. This may include allodynia, where a normally non-painful stimulus is perceived as painful. Assessing the patient's response to a pin-prick can be used to test for abnormalities in mechanical hyperalgesia. Finally, touching the patient's skin with warm and cool thermal rollers can be used to test for abnormalities of thermal sensation. An unaffected area of skin should be tested first, to establish normal sensation, before testing the affected area.

#### Nerve conduction studies

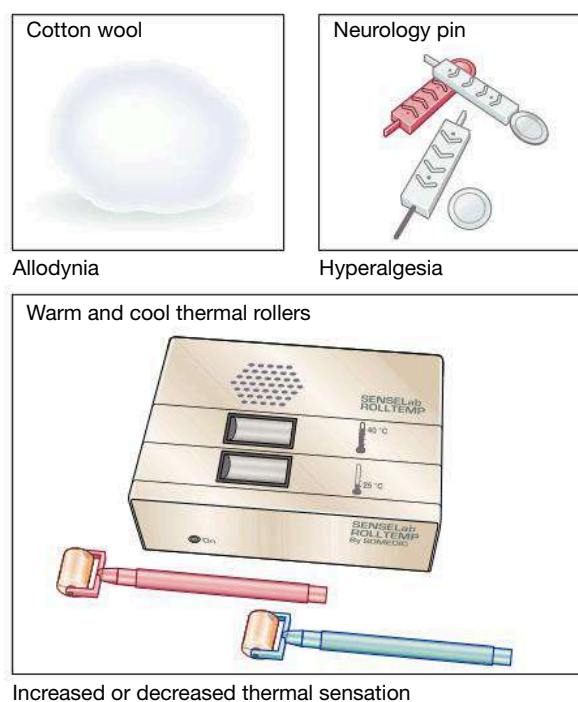

Nerve conduction studies can be helpful in demonstrating and quantifying a definitive nerve lesion, either peripherally or centrally. They can be used to help differentiate between central and peripheral neuropathic pain. They do not, however, effectively examine small nerve fibre function.

#### Nerve blocks

Performing a nerve block with infiltration of a local anaesthetic such as 1% lidocaine can be used diagnostically, in assessing whether a pain syndrome is due to involvement of a specific nerve or nerve root. Where inflammation and or swelling may be contributing to the underlying pain – for example, if there is compression of a nerve root – then a mixture of local anaesthetic and depot glucocorticoid may be helpful in alleviating pain. Nerve blockade can also be used to determine whether more radical therapies, such as nerve ablation, might be helpful in controlling pain, particularly that related to cancer.

#### Pain scoring systems

Various questionnaires and other instruments have been devised to localise pain, rate its severity and assess its impact on quality of life. Some of the most widely used are listed in [Box 8.4](#). The distribution of pain can be documented on a diagram of the body, on which the patient can mark the sites that are painful. Similarly, other methods have been developed with which to assess the severity of pain using verbal, numerical and behavioural rating scales. Visual scoring systems employing different facial expressions may be of value in paediatric patients and those

**Fig. 8.5** Equipment for bedside sensory testing.

with cognitive impairment. Documenting changes in pain scores using questionnaires can be helpful in indicating to what extent drug treatments have been successful and can reduce the time taken to achieve pain control.

#### Principles of management

Effective management of chronic pain depends in part on the underlying cause but some general principles can be applied. In general terms, the treatment goals are to:

- educate the patient
- promote self-management
- optimise function
- enhance quality of life
- control pain.

## Clinical history

### Biopsychosocial assessment

A full biopsychosocial assessment should be performed in all patients with chronic pain. Although this is time-consuming, the time invested is likely to pay dividends in improving the long-term outcome for patients. A biopsychosocial assessment takes account of the underlying neurobiology of the condition in the context of wider influences, including cognition and beliefs, emotions, and social and cultural factors. For example, an individual with abdominal pain might respond differently if a close

relative had recently died of gastric cancer than if a colleague had been off work with gastric upset.

An accurate clinical history is important, taking note of the duration of pain, any precipitating and relieving factors, its location and, if the pain is located at more than one site, which site is the one that impacts most on the patient's quality of life. The characteristics of the pain should be documented, by assessing whether it is described as dull, sharp, aching or burning. Associated features, such as hypersensitivity to fine touch or temperature, numbness, paraesthesia, tingling and formication (the feeling of insects crawling over the skin), should be noted. It is important to determine to what extent the pain is interfering with normal daily activities, such as work, leisure pursuits and sleep. The patient's social circumstances and cultural background should be documented, including any caring responsibilities, employment status and social and family support. The intensity of pain should also be recorded, preferably using a validated questionnaire (see [Box 8.4](#)). The patient's mood should be assessed and, if evidence of low mood is detected, a suicide risk assessment should be considered (see [Box 31.14](#)). The past medical and medication history should be recorded and specific enquiry made about substance misuse and any previous history of physical or mental abuse. This should be approached sympathetically, with information about how to access appropriate support if required. It is also useful to enquire specifically about the patient's beliefs as to what is causing their pain, as well as what their expectation of treatment is; unless these are addressed, management may be less effective. There are some patient populations in whom particular challenges arise, often related to differences in communication ability. Strategies that can be used to overcome these difficulties are summarised in [Box 8.5](#).

8

### 8.4 Instruments used in the assessment of pain and its impact

Instrument	Comments
<b>Brief Pain Inventory</b>	Developed for use in cancer pain, validated and widely employed for chronic pain; based on 0–10 ratings of pain intensity and the impact of pain on a range of domains, including sleep, work and enjoyment of life
<b>Pain Detect, s-LANSS, DN-4</b>	A number of screening questionnaires to aid diagnosis of neuropathic pain
<b>Pain Catastrophising Scale</b>	Developed to assess individual levels of catastrophising, encompassing three different domains: helplessness, rumination and magnification
<b>Tampa Scale of Kinesiophobia</b>	Measures how much an individual is fearful of movement
<b>Pain Self-efficacy Questionnaire</b>	Assesses individual beliefs about self-efficacy in the context of chronic pain, and how this impacts on function
<b>Visual analogue scale (VAS)</b>	Patient marks pain intensity on a horizontal line
<b>Localisation of pain</b>	Body chart, allowing the patient to indicate where pain is situated
<b>Beck Depression Inventory</b>	Assesses emotional function
<b>SF-36/EQ-5D</b>	Assesses health-related quality of life

(DN-4 = Douleur Neuropathique questionnaire; EQ-5D = EuroQol 5-Domain questionnaire; SF-36 = Short Form 36; s-LANSS = self-completed Leeds Assessment of Neuropathic Signs and Symptoms)

### Examination

The patient's general appearance should be noted, including ability to walk and use of a walking aid. In those with focal pain, neurological examination should be performed, focusing particularly on any areas of abnormal sensation, reflexes and evidence of muscle wasting. A general examination should be carried out to determine whether there is any evidence of an underlying physical disorder that can account for the pain. In addition to the use of investigations to find the underlying cause of pain, patients with persistent or chronic pain may benefit from sensory testing or diagnostic nerve blocks to explore the underlying mechanisms and direct treatment. For example, a combined femoral and sciatic nerve block may be used in a patient with lower limb amputation to assess whether the pain is predominantly peripherally or centrally generated. If the pain is not improved by an effective nerve block, then peripherally directed therapies are unlikely to be effective.

### 8.5 Challenges in pain assessment in particular patient populations

Patient population	Challenges	Solutions
<b>Paediatric</b>	Assessment needs to be appropriate to developmental stage	Consider visual tools to aid pain assessment
<b>Older adults</b>	May have impaired cognitive function Cultural factors may reduce self-reporting of pain Risk of adverse effects of medication increased	Consider formal assessment of cognitive function Consider non-verbal assessment Consider visual tools to assess pain Employ a number of tools assessing pain behaviours
<b>Cognitive impairment</b>	Reporting and expression of pain may change Increased sensitivity to central nervous system effects of analgesics	Perform formal assessment of cognitive function Use non-verbal assessment: facial expressions, vocalisations, body movements, changes in social interactions
<b>Substance misuse</b>	Response to analgesics altered Increased tolerance Increased risk of addiction Substance misuse may affect reporting of pain	Seek specialist support early Ensure prescribing is safe

## Interventions

Probably the most effective mode of treatment for pain is to identify the underlying cause. Examples include the use of immunosuppressive medication in inflammatory disease, chemotherapy, radiotherapy or hormone therapy in cancer, and antimicrobial therapy in patients with infection. There are many circumstances, however, in which the underlying cause of pain cannot be treated or the treatments available are incompletely effective. Under these circumstances, several management options are available. In all cases, a multidisciplinary approach is necessary that combines pharmacological management with supported self-management, and other specific interventions when appropriate.

## Supported self-management

Self-management strategies are useful in the treatment of chronic pain. Self-management works best if the patient has some understanding of their chronic pain, and acceptance that it is unlikely to resolve completely. The aim is for patients to maximise their quality of life and function *despite* ongoing pain. Support for self-management can be delivered by health-care professionals, patients who suffer from the same condition or lay people, either on an individual basis, in a group setting or, increasingly, through web-based resources. There is a strong educational component to supported self-management, which seeks to generate an interaction between patient and tutor. The key aspects include:

- increasing activity levels, while understanding and practising pacing techniques (not overdoing things and cycling between over- and under-activity)
- using relaxation and mindfulness techniques as part of daily management
- using medication when appropriate
- having a plan to manage pain flares.

All these are covered in formal pain management programmes (see 'Psychological therapies'), where a structured approach is used, in a group-based setting, to address all these aspects with expert multidisciplinary input, that may include psychologists, occupational therapists, nurses, pharmacists and pain medicine specialists.

For less complex cases, or to provide ongoing support, there are a number of useful online self-help resources (see 'Further information').

## Physical therapies

There is strong evidence that exercise can help in the management of chronic pain. Several types of exercise have been successfully delivered in various ways, through physiotherapists, exercise classes or individual tuition. In choosing a form of exercise therapy, it is important to tailor the approach most likely to be acceptable to the individual patient. A successful exercise programme can help overcome 'fear avoidance', a well-recognised problem in chronic pain, where patients associate activity with an increase in pain and therefore do progressively less activity, with resultant deconditioning. Because of this it is important to pace physical activity to ensure that patients do not cycle from over-activity,

### 8.6 Physical therapies for chronic pain

- Exercise classes

with a flare in pain, to fatigue and deconditioning. This can be done by working with patients to establish their baseline level of activity and using an individually tailored, graded exercise programme (Box 8.6). This may include normal household activities, as well as targeted exercises and stretches. Manual therapy covers a variety of hands-on treatments, including manipulation, mobilisation and massage. Manual therapy can be provided by a range of therapists, including physiotherapists, osteopaths and chiropractors. There is some evidence of short-term benefit for manual therapy but limited evidence of long-term efficacy.

## Pharmacological therapies

A range of analgesics can be used in the management of chronic pain but, for most of these, the evidence of long-term benefit is limited, and there may be considerable risks associated with long-term use for some agents. If using analgesics as part of a holistic treatment plan (e.g. to manage short-term flare-ups, or target neuropathic pain), in general, it is advisable to use a multimodal approach, choosing different drugs to target pain processing at multiple points (Box 8.7). By employing different classes of analgesic, it is possible to use lower doses of each, thereby improving the side-effect profile and reducing risk. There is considerable inter-individual variability in response to analgesics, even within the same class. There are many reasons for this, including genetic variations in the enzymes that metabolise drugs. For example, the *CYP2D6* gene encodes for a liver enzyme, cytochrome P450 2D6, which metabolises a number of commonly used analgesics. Genetic variation in *CYP2D6* can influence circulating levels of many drugs, depending on whether someone is a rapid or poor metaboliser. This is particularly important if metabolites are active, as is the case with codeine and dihydrocodeine, which are metabolised to morphine. Genetic variations have also been described in the opioid receptors and downstream pathways that they affect, with good pre-clinical evidence that variations in mu opioid receptors alter analgesic response to different opioids. Because of this there is a good rationale to try different drugs, even ones from the same class, if there is an inadequate response or there are unacceptable side-effects with one agent.

Whatever drug or combination of drugs is chosen, the key to successful pharmacological management is careful assessment and review, aiming for an acceptable balance between the benefits of treatment in providing pain relief, maximising function, and improving quality of life and adverse effects. Specific drug treatments are described below.

### Non-opioid analgesics

#### Paracetamol

Paracetamol is widely used in the treatment of mild to moderate pain. Its mechanism of action is incompletely understood but it is known to be a weak inhibitor of the cyclo-oxygenase type 1 (COX-1) and cyclo-oxygenase type 2 (COX-2) enzymes, providing weak anti-inflammatory properties. There is also some evidence that it activates inhibitory descending spinal pathways, via a serotonergic mechanism. Other postulated mechanisms include endocannabinoid re-uptake inhibition, and inhibition of nitric oxide and tumour necrosis factor alpha. For migraine and tension-type headache it has moderate efficacy at a dose of 1000mg. It is used widely for musculoskeletal disorders and osteoarthritis, with very little high-quality evidence that it is much better than placebo, even at doses of up to 4000mg per day. Acute liver failure is a well-recognised complication of paracetamol overdose but this risk may also be increased with long-term use, even within the recommended dose range. In view of this, it should be employed with caution in older patients and those weighing less than 50kg.

#### Non-steroidal anti-inflammatory drugs

Non-steroidal anti-inflammatory drugs (NSAIDs) are widely used in the treatment of inflammatory pain and osteoarthritis. These drugs can be given systemically or locally and are discussed in more detail in Chapter 26. They are also useful in the management of pain in cancer patients, as discussed later in this chapter. Although widely prescribed, there is

## 8.7 Pharmacological management of chronic pain

Drug or class of drug	Mechanism of action
Paracetamol	Central inhibition of COX-1 and COX-2 enzymes Mechanisms of action incompletely understood
Non-steroidal anti-inflammatory drugs	Inhibition of prostaglandin production
Opioids	Agonists at opioid receptors at multiple levels in the central nervous system Blockade of ascending pain pathways
Ketamine	Antagonist of NMDA receptors Reduction of central sensitisation
Gabapentin and pregabalin	Inhibition of glutamate release by primary afferent neurons at first central synapse Decrease of excitatory neuronal activity
Tricyclic antidepressants	Inhibition of serotonin and noradrenaline (norepinephrine) re-uptake at synapses in the spinal cord, and also potential effects in the limbic system Inhibition of Na <sup>+</sup> channels in neurons
Serotonin (5-hydroxytryptamine, 5-HT) and noradrenaline (norepinephrine) re-uptake inhibitors	Inhibition of serotonin and noradrenaline re-uptake at synapses in the spinal cord, and also potential effects in the limbic system
Lidocaine patches	Inhibition of Na <sup>+</sup> in sensory neurons
Capsaicin patch	Activation of TRPV1 channels on subset of C fibres, causing selective pharmacological denervation, with a decrease in intra-epidermal nerve fibre density
Nerve blocks with lidocaine and glucocorticoids	Temporary denervation due to blockade of Na <sup>+</sup> channels in sensory neurons Local anti-inflammatory effect

(COX = cyclo-oxygenase; NMDA = *N*-methyl-D-aspartate; OP = opioid; TRPV1 = transient receptor potential vanilloid 1)

limited high-quality evidence of long-term efficacy in chronic pain, and concerns about risks of long-term use particularly around cardiovascular and renal effects. There is a clear need for further studies in this area.

### Topical analgesics

Topical capsaicin cream (0.025 or 0.075%) has some efficacy for osteoarthritis and may be used for neuropathic pain, although evidence of benefit is limited. A single application (done by a trained health-care professional) of a high-dose 8% capsaicin patch can give around 12 weeks of pain relief for neuropathic pain and can be repeated thereafter. Capsaicin is an agonist at the transient receptor potential vanilloid 1 (TRPV1) ion channel, found on some C fibres. Capsaicin activates the channel, causing an initial sensation of heat, but an analgesic effect subsequently results due to desensitisation of the channel, with a reduction in intra-epidermal nerve fibre density.

Lidocaine 5% patches can also be helpful in focal neuropathic pain and should be applied for 12 hours out of 24 hours, with up to 4–6 weeks before maximum benefit is seen. The mode of action is blockade of sodium channels in primary afferent neurons and nociceptors, which reduces peripheral input to the spinal cord.

### Anti-neuropathic agents

Anti-neuropathic agents are also termed 'adjuvant analgesics'. This term is used to cover a range of medicines that are employed in the treatment of neuropathic pain, and in certain patients with CWP. It should be noted that these medicines should only be used as part of a holistic management plan, including physical and psychological therapies, sometimes in combination with classical analgesics. Typically, these agents do not produce an immediate reduction in pain, but rather exert an analgesic effect over a longer timeframe through their effects on central processing of pain. They are of particular value when used in combination in the management of pain with a neuropathic component but require careful dose titration over a number of weeks, to reach a dose that balances efficacy with side-effects. While the response to individual agents is variable, it is often possible to find an agent or combination of agents that works for most patients.

In the majority of current recommendations, including those from the International Association for the Study of Pain, first-line treatments include antidepressants such as serotonin noradrenaline reuptake

inhibitors (mainly duloxetine) or tri-cyclic anti-depressants such as amitriptyline and nortriptyline. Anti-epileptic agents such as gabapentin or pregabalin are also recommended for use as second-line treatments, although there is increasing concern around their abuse potential and association with an increase in drug deaths.

### Opioid analgesics

Opioids have been used for centuries to reduce pain, and were originally obtained from the resin of the opium poppy (*Papaver somniferum*). Over recent years, new synthetic opioids such as fentanyl, oxycodone and tramadol have been introduced. The pharmacological effects of opioids are mediated by binding to a number of opioid receptors which are G-protein-coupled receptors, as summarised in [Box 8.8](#). When opioids bind to their receptors, several intracellular signalling pathways are activated, increasing cyclic adenosine monophosphate (cAMP) levels and altering calcium and potassium permeability of neurons. Opioids are traditionally divided into subclasses of weak opioids, such as codeine and dihydrocodeine, and strong opioids, such as morphine and oxycodone. While tramadol is a weak agonist at the mu opioid receptor, it is classified as a strong opioid in some countries. Codeine and dihydrocodeine are metabolised in the liver to morphine by *CYP2D6* at a rate that is genetically determined. Similarly, tramadol is metabolised by *CYP2D6* to yield *o*-desmethyltramadol, which has greater affinity than tramadol for opioid receptors. Up to 10% of people are rapid metabolisers and this may be associated with differences in efficacy and adverse effects of these drugs between individuals (see [Box 2.5](#)). The dosages and characteristics of commonly prescribed opioids are shown in [Box 8.9](#). There has been a large increase in the use of strong opioids for chronic pain over the last few decades, to the extent that it has been referred to as an 'opioid epidemic'. A number of factors contribute to this, including a rising incidence of chronic pain with an ageing population, reluctance to use NSAIDs because of cardiovascular and gastrointestinal adverse effects, changes in patient expectation, societal attitudes and availability of new formulations of opioids. There is very limited evidence of short- to medium-term benefit for strong opioids in low back pain and osteoarthritis with more recent longer-term evidence finding no improvement in function, worse pain and increased side-effects in people on opioids compared to non-opioid analgesia. More good-quality studies of

8.8 Endogenous opioids and opioid receptors				
Endogenous ligand	Receptor (IUPHAR)	Alternative classification	Potential sites	Pharmacological effects
Endomorphin 1 and 2 Met-enkephalin Dynorphin A Dynorphin B	MOP	Mu	Brain, spinal cord, peripheral nerves, immune cells	Analgesia, reduced gastrointestinal motility, respiratory depression, pruritus
Leu-enkephalin Met-enkephalin $\beta$ -endorphin	DOP	Delta	Brain, spinal cord, peripheral nerves	Analgesia, cardioprotection, thermoregulation
Dynorphin A Dynorphin B $\beta$ -endorphin	KOP	Kappa	Brain (nucleus accumbens, neocortex, brainstem, cerebellum)	Analgesia, neuroendocrine (hypothalamic–pituitary axis), diuresis, dysphoria
Orphanin FQ (nociceptin)	NOP	Orphan	Nucleus raphe magnus, spinal cord, afferent neurons	Opioid tolerance, anxiety, depression, increased appetite

It is thought that opioids used clinically act through the MOP.  
(IUPHAR = International Union of Basic and Clinical Pharmacology)

8.9 Commonly used opioids				
Opioid	Typical starting dose	Route	Oral morphine equivalent	Comments
Morphine	10 mg	Oral	10 mg	Most widely used
Codeine	30–60 mg; max 240 mg/24 hr	Oral	3–6 mg	Metabolised to morphine by <i>CYP2D6</i> enzyme
Dihydrocodeine	60 mg; max 240 mg/24 hr	Oral	6 mg	Metabolised to morphine by <i>CYP2D6</i> enzyme
Tramadol	100 mg; max 400 mg/24 hr	Oral	10 mg	Metabolised to o-desmethyl tramadol by <i>CYP2D6</i> enzyme
Oxycodone	6.6 mg	Oral	10 mg	More predictable bioavailability than morphine
Buprenorphine	5 $\mu$ g/hr	Transdermal	12 mg/day	Patch change usually every 7 days (frequency of change dependent on manufacturer and dose); advantages in impaired renal function
Fentanyl	12 $\mu$ g/hr	Transdermal	30 mg/day	Use with care in opioid-naïve patients; patch change usually every 72 hrs
Tapentadol	50 mg; max 600 mg/24 hr	Oral	20 mg	Use with care in opioid-naïve patients
Hydromorphone	2 mg	Oral	10 mg	Semi-synthetic; hepatic metabolism
Morphine	3 mg	Subcutaneous, intramuscular, intravenous	10 mg	Mainly used for acute pain or palliative care

long-term use are needed. Additionally, there is increasing concern about potential harm from long-term use. This includes addiction, dependence, opioid-induced hyperalgesia, endocrine dysfunction, fracture risk (especially in older people), overdose and cardiovascular events, with many of these adverse effects being dose-related. Doses of more than 50 mg morphine equivalents per day may be detrimental, with an increased in harm at doses of >90 mg morphine equivalents per day. National and international guidelines have changed to reflect this, with most only recommending short- to medium-term use of opioids in carefully selected patients, as part of a holistic management plan. Regular review is essential to assess ongoing benefit, and any opioid trial should have clear goals, and a plan for cessation if these are not reached. A suggested strategy for using strong opioids in chronic pain is shown in [Box 8.10](#).

## Psychological therapies

The aims of psychological therapy are to increase coping skills and improve quality of life when facing the challenges of living with chronic pain. There are a range of ways in which psychological therapies can be delivered, including individual one-to-one sessions, group sessions,

multidisciplinary pain management programmes, or web-based or telephone-based programmes.

There is good evidence for the use of a cognitive behavioural therapy (CBT)-based approach for chronic pain, delivered either individually or in a group. The overall aim is to reduce negative thoughts and beliefs, and develop positive coping strategies. The interaction between thoughts, behaviours and emotions is explored, and a problem-focused approach is used in therapy delivery.

Relaxation techniques, such as biofeedback and mindfulness meditation, require a degree of stillness and withdrawal, with regular practice required for sustained benefit (see 'Further information'). Acceptance and commitment therapy (ACT) is based on CBT principles but also uses components of mindfulness to improve psychological flexibility in the context of living with chronic pain.

## Stimulation therapies

These range from minimally invasive procedures like acupuncture and transcutaneous electrical nerve stimulation (TENS) to more invasive techniques such as spinal cord stimulation.

## i

## 8.10 Use of opioids in chronic pain: Always use as part of a holistic management plan

Step	Factors to take into account	Comment
1. Assess suitability for opioids	Type of pain Likelihood of dependence Co-morbidity	Neuropathic pain and chronic widespread pain less likely to respond Increased risk in those with history of alcohol and substance misuse Avoid use in conditions where adverse effects more likely: Chronic obstructive pulmonary disease Chronic liver disease Chronic kidney disease
2. Discuss with patient	Discuss potential benefits  Discuss adverse effects  Establish treatment goal	Improvement in pain Improvement in function Nausea Constipation Drowsiness Improvement in function
3. Plan treatment trial	Set timescale  Agree on dose  Agree on stopping rules	Define duration of treatment Agree frequency of review Aim for lowest effective dose Set upper dose limit Consider stopping if: Treatment goal is not met There is no dose response Tolerance develops rapidly

Acupuncture (Fig. 8.6) has been used successfully in Eastern medicine for centuries. The mechanisms are incompletely understood, although endorphin release may explain, in part, the analgesic effect. Acupuncture is particularly effective in pain related to muscle spasm, with some evidence of short-term benefit for patients with low back pain. Similar mechanisms probably apply to TENS, which is worth considering in many types of chronic pain. Neuromodulation, using implanted electrodes in the epidural space (or, more recently, adjacent to peripheral nerves), has been shown to be an effective option for neuropathic pain, including failed back surgery syndrome and chronic regional pain syndrome (see below). Specialist assessment and ongoing support is necessary, as there are many potential complications, including infection, malfunction and battery failure. The likelihood of success is increased when this technique is used within the context of multidisciplinary assessment and management.

### Complementary and alternative therapies

Complementary techniques, such as herbal medicines, vitamins, homeopathy and reflexology, have been used for the treatment of chronic pain but with little evidence of efficacy. It should be noted that herbal medications may interact with conventional drugs, causing adverse effects as the result of drug–drug interactions. St John's wort (*Hypericum perforatum*) interacts with many drugs, including many antidepressants used in chronic pain, with increased serotonergic effects. Grapefruit may also increase the risk of serotonergic effects with some antidepressants. *Ginkgo biloba* may interact with paracetamol to increase bleeding time.

### Nerve blocks and nerve ablation

The use of specialist nerve blocks and nerve ablation therapy can be considered for pain that is unresponsive to less invasive approaches. If these are being considered, they should form part of a multidisciplinary management plan, with the aim of restoring function and reducing pain. Local anaesthetic with or without depot glucocorticoid (non-particulate for neuraxial administration) can be effective in some circumstances. Examples include occipital nerve blocks for migraine or cervicogenic headache and trigger point injections for myofascial pain. If there is limited compression of a spinal nerve root, the nerve root injections into the epidural space may help settle symptoms and

Fig. 8.6 Acupuncture.

avoid the need for surgical intervention. Neurodestructive procedures can also be employed for intractable pain but are rarely used outside the palliative care setting.

### Chronic pain syndromes

Chronic pain is a feature of several recognised syndromes, which are discussed in more detail below.

### Neuropathic pain

Neuropathic pain is defined as 'pain associated with a lesion or disease of the somatosensory nervous system'. Neuropathic pain may be acute, such as in sciatica, which occurs as the result of a prolapsed disc, but is most problematic when it becomes chronic. Neuropathic pain causes major morbidity; in a recent study, 17% of those affected rated their

8.11 Clinical features of neuropathic pain		
Characteristic	Symptom or clinical feature*	Descriptive term
Spontaneous pain	No stimulus required to evoke pain	
Positive sensory disturbance	Light touch painful Pressure painful Increased pain on pin-prick Cool and warm temperatures painful	Dynamic allodynia Punctate allodynia Hyperalgesia Thermal allodynia
Negative sensory disturbance	Numbness Tingling Loss of temperature sensitivity	Loss of sensation Paraesthesia
Other features	Feeling of insects crawling over skin Affected area feels abnormal	Formication Dysaesthesia

\*Symptoms may cluster, with a predominance of either positive or negative symptoms, or a mixture of both, reflecting differences in underlying mechanisms.

quality of life as 'worse than death'. The clinical features of neuropathic pain are summarised in Box 8.11. The diagnosis is easily missed and so careful assessment is vital, in order to make the diagnosis in the first place and then to direct management appropriately. An algorithm for the management of neuropathic pain is provided in Figure 8.7. It is important to recognise the negative impact of neuropathic pain on quality of life, which has been shown to be greater than with other types of chronic pain. As a result, appropriate support and multidisciplinary management should always be considered in addition to pharmacological therapies.

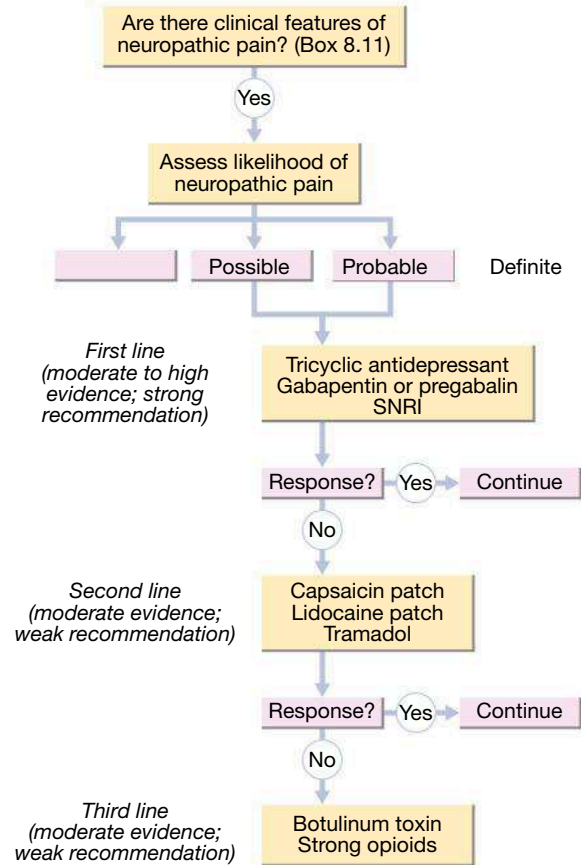

### Complex regional pain syndrome

Complex regional pain syndrome (CRPS) is a type of neuropathic pain that affects one or more limbs. It was previously termed reflex sympathetic dystrophy (RSD), reflecting the fact the disease is thought to be caused in part by an abnormality in the autonomic nervous system. It is a rare syndrome, occurring in about 20 per 100000 individuals, and is more common in females, typically presenting between the ages of 35 and 50. It is classified into type 1 CRPS, which may be precipitated by a traumatic event such as a fracture but is not associated with peripheral nerve damage, and type 2 CRPS, which is associated with a peripheral nerve lesion. The diagnosis is primarily clinical, with the current standard being based on the Budapest criteria, as outlined in Box 8.12. Other diagnostic tools, none of which provide a definitive diagnosis, include thermography (temperature difference of  $>1^{\circ}\text{C}$ ), and electromyography (if myoclonus is a feature). Increased tracer uptake on radionuclide bone scan and bone marrow oedema on MRI scan may be observed in CRPS but the diagnosis is primarily clinical, as outlined in Box 8.12.

Prompt diagnosis and early treatment with physiotherapy, and additional approaches such as desensitisation, and graded motor imagery, may prevent progression of symptoms. Pharmacological management is similar to that for neuropathic pain. Specific approaches (with variable quality evidence) that may be considered include bisphosphonates or calcitonin. Intravenous regional block with guanethidine is not recommended, as there is limited evidence of benefit, and an increased risk of adverse effects. If medical management is incompletely effective, consideration should be given to the appropriateness of a spinal cord stimulator, with reasonable evidence of efficacy.

### Phantom limb pain

Phantom limb is a common complication of amputation, occurring in up to 70% of patients. It is a form of neuropathic pain but can

**Fig. 8.7** Algorithm for pharmacological management of neuropathic pain.

(SNRI = serotonin noradrenaline (norepinephrine) re-uptake inhibitor) Adapted from SIGN 136 and NeuPSIG recommendations; reproduced from Finnerup NB, Attal N, Haroutounian S, et al. Pharmacotherapy for neuropathic pain in adults: a systematic review and meta-analysis. *The Lancet Neurol* 2015; 14:162–173, with permission from Elsevier.

be particularly distressing, as the pain is felt in the area where the absent limb was previously. Although usually presenting after limb amputation, reports of phantom pain in other body parts have been reported, such as phantom breast pain following mastectomy. It is very often associated with phantom sensations, which are described as non-painful sensations in the absent body part and pain in the stump.

Diagnostic nerve blocks may be helpful in directing therapy, with use of anti-neuropathic medications as outlined in Box 8.7. If there is a definite neuroma at the stump site that is interfering with prosthesis use, surgical review may be necessary. Management should use rehabilitation approaches with physical therapy. Additional approaches such as mirror visual feedback and desensitisation may also be considered.

### Chronic widespread pain

Chronic widespread pain (CWP) is often associated with other features, such as fatigue and irritable bowel syndrome. Fibromyalgia is a subtype of CWP in which there are myofascial trigger points, and is often associated with sleep disturbance. Clinical features and management of fibromyalgia are discussed in more detail in Chapter 26.

### Joint hypermobility syndrome

Hypermobility can be associated with chronic musculoskeletal pain that often targets the joints and periarticular tissues. It is thought to be caused by abnormal stresses being placed on the joints and surrounding

## 8.12 The Budapest criteria for diagnosis of complex regional pain syndrome (CRPS)

Category	Symptom or sign
<b>Sensory</b>	Allodynia to: Temperature Light touch Deep somatic pressure Movement Hyperalgesia to pin-prick
<b>Vasomotor</b>	Temperature asymmetry Skin colour change and/or asymmetry
<b>Sudomotor</b>	Oedema Sweating change and/or asymmetry
<b>Motor/trophic</b>	Reduced range of motion Motor dysfunction: Weakness Tremor Dystonia Trophic changes: Hair Nails Skin

Type 1 CRPS: without evidence of major nerve damage; type 2 CRPS: evidence of major nerve damage. For a positive diagnosis, the patient should report at least one symptom in at least three out of the four categories, and at least one sign should be detected in two out of the four categories. Other causes that might explain the signs and symptoms should be excluded.

soft tissues due to ligament laxity, although the mechanisms are poorly understood since many people with hypermobile joints do not suffer pain. It is described in more detail in [Chapter 26](#).

## Palliative care

Palliative care is the term used to describe the active total care of patients with incurable disease. It can be distinguished from end-of-life care, which refers to the care of patients with far advanced, rapidly progressive disease that will soon prove fatal. The focus of palliative care is on symptom control alongside supportive care. While palliative care can and should be delivered at any stage of an incurable illness alongside optimal disease control, the focus of end-of-life care is on quality of life rather than prolongation of life or cure. Palliative care encompasses a distinct body of knowledge and skills that all good physicians must possess to allow them to care effectively for patients. Palliative care is seen traditionally as a means of managing distress and symptoms in patients with cancer, when metastatic disease has been diagnosed and death is seen as inevitable. However, prognosis in metastatic cancers has evolved significantly with the emergence of improved anti-cancer treatments, hence the principle of delivering palliative and supportive care whenever a patient needs it, as opposed to a specific stage of disease, is now even more important. There is also a growing recognition that the principles of palliative care and some of the interventions it uses are equally applicable in other conditions. Palliative care may be applied to any chronic disease state. Which elements are used will depend on the individual patient's need.

For conditions other than cancer, the challenge is recognising when patients have entered the terminal phase of their illness, as there are fewer clear markers and the course of the illness is much more variable. Different chronic disease states progress at different rates, allowing some general trajectories of illness or dying to be defined ([Fig. 8.8](#)). These trajectories are useful in decision-making for individual patients but also in the planning of services.

The 'rapid decline' trajectory following a gradual decline, as occurs in cancer, is the best-recognised pattern of the need for palliative care,

**Fig. 8.8** Archetypal trajectories of dying. From Murray SA, Kendall M, Boyd K, et al. *Illness trajectories and palliative care*. *BMJ* 2005; 330:7498; reproduced with permission from the BMJ Publishing Group.

although a similar trajectory may be observed in other conditions, such as motor neuron disease. Many traditional hospice services are designed to meet the needs of people on this trajectory. Over recent years, improvements in management of malignant disease mean that some types of cancer may follow an erratic or intermittent decline trajectory.

Many chronic diseases, such as advanced chronic obstructive pulmonary disease (COPD) and intractable congestive heart failure, carry as high a burden of symptoms as cancer, as well as psychological and family distress. The 'palliative phase' of these illnesses may be more difficult to identify because of periods of relative stability interspersed with acute episodes of severe illness. However, it is still possible to recognise those patients who may benefit from a palliative approach to their care. The challenge is that symptom management needs to be delivered at the same time as treatment for acute exacerbations. This leads to difficult decisions as to the balance between symptom relief and aggressive management of the underlying disease. The starting point of need for palliative care in these conditions is the point at which consideration of comfort and individual values becomes important in decision-making, often alongside management of the underlying disease.

The third major trajectory is categorised by years of poor function and frailty before a relatively short terminal period; it is exemplified by dementia but is also increasingly true for patients with many different chronic illnesses. As medical advances extend survival, this mode of dying is being experienced by increasing numbers of people. The main challenge lies in providing nursing care and ensuring that plans are agreed for the time when medical intervention is no longer beneficial.

In a situation where death is inevitable and foreseeable, palliative care aims to strike a balance between addressing the wishes, expectations and values of the patient with a realistic assessment of the benefits of medical interventions. This often results in a greater focus on comfort, symptom control and support for patient and family, and may enable withdrawal of both futile and burdensome interventions. In cases of prognostic uncertainty, open, honest and gentle communication with the patient and family is important. The most common symptoms in palliative care are discussed in the next section. The central networks we have heard about above in relation to chronic pain also exist for all other symptoms. In addition there is an extra complexity in cancer as a result of the additional layer of biological complexity resulting from the factors released by the tumour such as pro-inflammatory cytokines and the body's response to these factors.

## Presenting problems in palliative care

### Pain

Pain is a common problem in palliative care. It has been estimated that about two-thirds of patients with cancer experience moderate or severe pain, and a quarter have three or more different sites of pain. Many of

these are of a mixed aetiology and about half of patients with cancer-associated pain have a neuropathic element.

### Clinical assessment

The commonest barrier to assessment of pain is the development of idiosyncratic shortcuts in the belief that these are also easier for the patient. A common example is, 'How is your pain?' The patient will often give a reflex response such as, 'OK', which might be documented by the clinician as 0, 1 or 2 out of 10. If the same patient were asked, 'Have you had any pain in the last 24 hours, on a scale of 0–10, where 0 is none at all and 10 is the worst imaginable?' the same patient might record a score as high as 8 or 9 out of 10. This emphasises the importance of using a validated question that screens for pain effectively.

Improved control of cancer-associated pain has been demonstrated with use of the Edinburgh Pain Assessment and management Tool (EPAT). This involves administration of a simple screening question about worst pain on a scale of 0–10 in the last 24 hours, followed by questions to identify specific pain/s such as neuropathic or bone, in addition to distress. The identified pains are linked to management algorithms. Review of pain and opioid side-effects completes the loop (see 'Further information').

Clinical features and suggested management strategies for common types of pain in cancer are shown in Box 8.13. The majority of patients with cancer-associated pain can be managed effectively using a stepwise approach, as outlined below.

### Management: pharmacological treatments

Pharmacological treatments are the mainstay of management in cancer-associated pain, however, they have to be underpinned by an appropriate assessment of pain and associated symptoms. In addition, non-pharmacological treatments and disease-modifying treatments run through each step of pain control. A stepwise approach is adopted, following the principles of the World Health Organization (WHO) analgesic ladder (Fig. 8.9), in which analgesia that is appropriate for the degree of pain is prescribed first. Patients with mild pain should be started on a non-opioid analgesic drug, such as paracetamol (maximum: 1 g 4 times daily) or an NSAID (step 1). If the patient fails to respond adequately or has moderate pain, a weak opioid, such as codeine (60 mg 4 times daily), should be added (step 2). This can be prescribed separately or in the form of the compound analgesic co-codamol. If pain relief is still not achieved or if the patient has severe pain, a strong opioid should be substituted for the weak opioid (step 3). If the pain is severe at the outset, strong opioids should be prescribed and increased or titrated according to the patient's response. It is important not to move 'sideways' (change from one drug to another of equal potency), which is a common problem during step 2 of the analgesic ladder.

In recent years there has been a tendency to use a low dose of a step 3 opioid rather than a traditional step 2 opioid such as codeine. It has now been demonstrated that it is safe, effective and has cost savings to miss out step 2 of the analgesic ladder. This is of great importance in low- and middle-income countries where step 2 drugs are usually much more expensive than morphine.

### Opioids

Opioid analgesia plays a key role in patients with moderate to severe pain. Its successful use depends on appropriate assessment and a detailed explanation to the patient and carer about the benefits and potential side-effects of therapy. Morphine is the most commonly prescribed strong opioid, although there are several alternatives, as outlined in Box 8.9.

Oral morphine takes about 20 minutes to exert an effect and usually provides pain relief for 4 hours. Most patients with continuous pain should be prescribed oral morphine every 4 hours initially, as this will provide continuous pain relief over the whole 24-hour period. Controlled-release morphine lasts for 12 or 24 hours, depending on the formulation, and if clinical circumstances dictate, a controlled-release formulation can be used to initiate and titrate morphine. The median effective morphine equivalent dose for cancer pain is about 200 mg per 24 hours.

8.13 Common types of pain in cancer		
Type of pain	Features	Management options
Bone pain	Tender area over bone Possible pain on movement	NSAIDs Bisphosphonates Radiotherapy
Increased intracranial pressure	Headache, worse in the morning, associated with vomiting and occasionally delirium	Glucocorticoids Radiotherapy Opioid
Abdominal colic	Intermittent, severe, spasmodic, associated with nausea or vomiting	Antispasmodics Hyoscine butylbromide Antiemetic and opioid may be required for intestinal obstruction
Liver capsule pain	Right upper quadrant abdominal pain, often associated with tender enlarged liver Responds poorly to opioids	Glucocorticoids
Neuropathic pain	Spontaneous pain Light touch, pressure and temperature changes are painful; increased pain on pin-prick Numbness, tingling or loss of temperature sensation Skin feels abnormal	Anticonvulsants: Gabapentin Pregabalin Antidepressants: Amitriptyline Duloxetine Ketamine
Ischaemic pain	Diffuse, severe, aching pain associated with evidence of poor perfusion Responds poorly to opioids	NSAIDs Ketamine
Incident pain	Episodic pain usually related to movement	Intermittent short-acting opioids Nerve block

(NSAIDs = non-steroidal anti-inflammatory drugs)

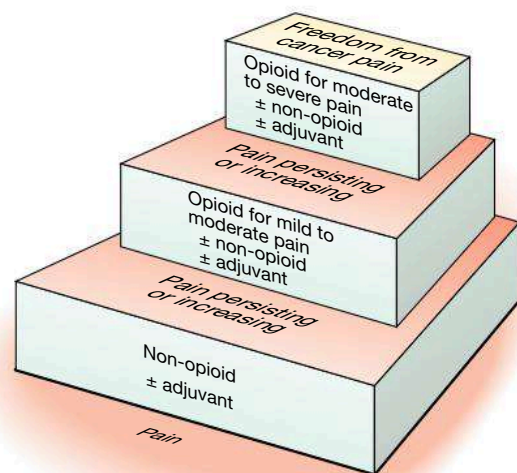

Fig. 8.9 The WHO analgesic ladder. From WHO. *Cancer pain relief*, 2nd edn. Geneva: WHO; 1996.

In addition to the regular dose of morphine, an extra dose of immediate-release (IR) morphine should be prescribed 'as required' for the treatment of breakthrough pain that has not been controlled by the regular prescription. As a rule of thumb, this additional dose should be one-sixth of the total 24-hour dose of opioid. The frequency of breakthrough

doses should be dictated by their efficacy and any side-effects, rather than by a fixed time interval. A patient may require breakthrough analgesia as frequently as hourly if pain is severe, but this should lead to early review of the regular prescription. The patient or carer should note the timing of any breakthrough doses and the reason for them. These should be reviewed daily and the regular 4-hourly dose increased for the next 24 hours on the basis of:

- the frequency of and reasons for breakthrough analgesia
- the degree and acceptability of side-effects.

The regular dose should be increased by adding the total of the breakthrough doses over the previous 24 hours, unless there are significant problems with unacceptable side-effects. When the correct dose has been established, a continuous release (CR) preparation can be prescribed, usually twice daily. Breakthrough analgesia used for movement-related pain is generally not included in background opioid dose titration. Attempts to control movement-related pain with background opioid dose will usually lead to over-dosing and opioid-related side-effects. This can be a risk in metastatic bone pain.

Some patients may have concerns about using opioids and it is vital for these to be explored. Patients should be reassured that psychological dependence is rare when opioids are used for cancer pain, unless a pre-existing dependence problem exists. Recent survey data from the United States have suggested that opioid abuse may occur in up to 20% of cancer patients, but to-date, these data have not been replicated in other countries. In fact, the majority of the world's population do not have any access to opioids for cancer pain relief. Good prescribing practice, clear communication and reassessment of benefits and side-effects are all critical in achieving good cancer pain relief. Pharmacological tolerance is not usually a clinically relevant problem; however, physical dependence, which is physiological, as manifest by a physical withdrawal syndrome, can occur if opioids are suddenly discontinued.

Nearly all types of cancer pain respond to morphine to some degree but there is a spectrum of response, such that in some patients the dose of opioid required to control neuropathic pain and all elements of metastatic bone pain may be high and associated with unacceptable side-effects. In these situations, other methods of analgesia, both pharmacological and non-pharmacological, should be explored and considered at an early stage.

The most effective and appropriate route of morphine administration is oral but transdermal preparations of strong opioids (usually fentanyl) are useful in certain situations, such as in patients with dysphagia or those who are reluctant to take tablets on a regular basis. Diamorphine is a highly soluble strong opioid used for subcutaneous infusions, particularly in the last few days of life, but is only available in certain countries and morphine is now the most commonly prescribed parenteral opioid.

### Opioid-related adverse effects

Adverse effects are a common problem with opioids, especially on initiating treatment and on increasing the dose. The most common side-effects are nausea, drowsiness, constipation and dry mouth, as summarised in [Box 8.14](#). Nausea and vomiting can occur initially but usually settle after a few days. Drowsiness is usually transient at opioid initiation and dose increase. If it is persistent, an alternative opioid and/or a non-opioid should be considered. In acute dosing, respiratory depression can occur but this is rare in patients on regular opioids or in those starting on small, regular doses with appropriate titration.

Tolerance usually develops to nausea, vomiting and drowsiness but not to constipation or dry mouth. All patients should therefore be prescribed a laxative, unless suffering from diarrhoea, and have access to an antiemetic and good mouth care, along with rationalisation of any concomitant medication that might exacerbate drowsiness. Newer developments include the use of preparations in which opioids are combined with opioid antagonists, such as naloxone. The naloxone is poorly absorbed and does not antagonise the systemic analgesic effect but

8.14 Opioid side-effects	
Side-effect	Management
Constipation	Regular laxative Opioid/naloxone oral combination, in resistant constipation
Dry mouth	Frequent sips of iced water, soft white paraffin to lips, chlorhexidine mouthwashes twice daily, sugar-free gum, water or saliva sprays
Nausea/vomiting	Oral haloperidol 0.5–1 mg at night, oral metoclopramide 10 mg 3 times daily or oral domperidone 10 mg 3 times daily If constant, haloperidol or levomepromazine may be given parenterally to break the nausea cycle
Sedation	Explanation is very important Symptoms usually settle in a few days Avoid other sedating medication where possible Ensure appropriate use of adjuvant analgesics that can have an opioid-sparing effect May require an alternative opioid

rather acts locally to block opioid receptors in the gut, thereby reducing opioid-related constipation. Vivid dreams, visual hallucinations (often consisting of a sense of movement at the periphery of vision), delirium and myoclonus are typical of opioid-related toxicity and, if present, require urgent reassessment of the opioid dose. Biochemistry should also be checked to exclude renal impairment, dehydration, electrolyte disturbance or hypercalcaemia.

Since opioid toxicity can occur at any dose, side-effects should be assessed regularly, but particularly after a dose increase. Pain should be reassessed to ensure that appropriate adjuvants are being used. Parenteral rehydration is often helpful to speed up excretion of active metabolites of morphine. The dose of opioid may need to be reduced or the opioid changed to a strong alternative.

Different opioids have different side-effect profiles in different people. If a patient develops side-effects, switching to an alternative strong opioid may be helpful. Options include oxycodone, transdermal fentanyl, hydromorphone and occasionally methadone, any of which may produce a better balance of benefit against side-effects. Fentanyl has no renally excreted active metabolites and may be particularly useful in patients with renal failure. Buprenorphine is also particularly useful in significant renal impairment. It is possible to switch between opioids but great care must be taken when doing so to make sure the dose is correct and to avoid prescribing too much or too little opioid.

### Adjuvant analgesics

An adjuvant analgesic is a drug that has a primary indication other than pain but which provides analgesia in some painful conditions and may enhance the effect of the primary analgesic. Commonly used adjuvant analgesics in the palliative care setting are shown in [Box 8.15](#). Some adjuvant analgesics may enhance the side-effect profile of the primary analgesic, and dose reductions of opioids may be required when an adjuvant analgesic is added. At each step of the WHO analgesic ladder, an adjuvant analgesic should be considered, the choice depending on the type of pain.

### Management: non-pharmacological treatments

#### Neurodestructive interventions

Neurodestructive techniques have an important role in the management of cancer pain, where life expectancy is limited. They should be used as part of an overall management plan and considered when the response to drug treatment has been inadequate. Intrathecal analgesia, delivered via either an external pump or a fully implanted device, is a good option,

8.15 Adjuvant analgesics in cancer pain			
Drug	Example	Indications	Side-effects*
<b>NSAIDs</b>	Diclofenac	Bone metastases, soft tissue infiltration, liver pain, inflammatory pain	Gastric irritation and bleeding, fluid retention, headache Caution in renal impairment
<b>Glucocorticoids</b>	Dexamethasone 8–16 mg per day, titrated to lowest dose that controls pain	Raised intracranial pressure, nerve compression, soft tissue infiltration, liver pain	Gastric irritation if used together with NSAID, fluid retention, proximal muscle myopathy, delirium, Cushingoid appearance, candidiasis, hyperglycaemia
<b>Anticonvulsants</b>	Evidence strongest for: Duloxetine Gabapentin Pregabalin	Neuropathic pain of any aetiology	Mild sedation, tremor, delirium Exacerbation of opioid-related side-effects
<b>Tricyclic antidepressants</b>	Amitriptyline Nortriptyline (less sedative)	Neuropathic pain of any aetiology	Sedation, dizziness, delirium, dry mouth, constipation, urinary retention Avoid in cardiac disease Exacerbation of opioid-related side-effects
<b>NMDA receptor blockers</b>	Ketamine	Severe neuropathic pain (only under specialist supervision)	Delirium, anxiety, agitation, hypertension

\*In old age, all drugs can cause delirium.  
(NMDA = *N*-methyl-*D*-aspartate; NSAIDs = non-steroidal anti-inflammatory drugs)

particularly where life expectancy is more than 3 months. Coeliac plexus blocks can be helpful for visceral pain, such as in pancreatic cancer. Lateral cordotomy to disrupt the spinothalamic tracts (either open or percutaneous) may be considered for unilateral chest wall pain, such as may occur in mesothelioma, where life expectancy is limited.

### Radiotherapy

Radiotherapy is the treatment of choice for pain from bone metastases (see Box 8.13) and can also be considered for metastatic involvement at other sites. All patients with pain secondary to bone metastases should be considered for palliative radiotherapy, which can usually be given in a single dose. Some patients experience a transient flare of pain after radiotherapy and this can be managed by 24–48 hours of dexamethasone (4–8 mg once in the morning).

### Physiotherapy

Physiotherapy has a key role in the multidisciplinary approach to a wide spectrum of cancer-related symptoms, including the prevention and management of pain, muscle spasm, reduced mobility, muscle wasting and lymphoedema. Rehabilitation in palliative care has expanded and now includes pre-habilitation, which involves the use of proactive focused exercise to maintain muscle mass during cancer chemotherapy and in other chronic conditions such as COPD.

### Psychological techniques

As with chronic pain, there is increasing use of psychological techniques in cancer pain management, which train the patient to use coping strategies and behavioural techniques. Other issues related to the specific experience of a cancer diagnosis and cancer treatment may be complex, and individual therapy in addition to group-based approaches can be helpful.

### Stimulation therapies

Acupuncture and TENS are low-risk stimulation therapies that may be useful in palliative care for management of pain and nausea. Both are particularly useful for secondary muscle spasm and TENS is increasingly used for bone pain.

### Complementary and alternative therapies

Palliative care patients often seek symptom relief from both complementary and alternative therapies. While the evidence base is poorly

developed, individual patients can gain significant benefits from the complementary therapies as outlined earlier in this chapter. It is critically important that patients are encouraged to discuss any alternative medicines they are considering, given the potential interactions with other therapies.

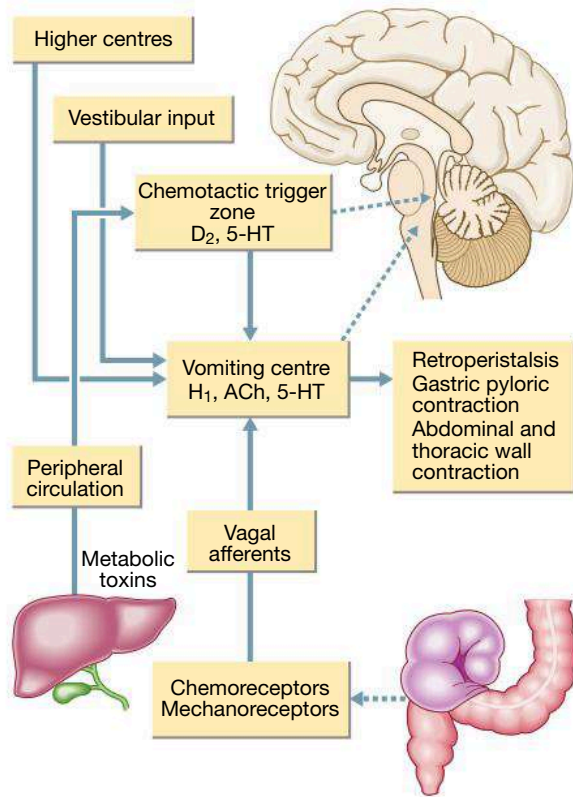

### Breathlessness

Breathlessness is one of the most common symptoms in palliative care and is distressing for both patients and carers. Patients with breathlessness should be fully assessed to determine whether there is a reversible cause, such as a pleural effusion, heart failure or bronchospasm; if so, this should be managed in the normal way. If symptoms persist, additional measures may be necessary. There are many potential causes of dyspnoea in cancer patients and in other chronic diseases; apart from direct involvement of the lungs, muscle loss secondary to cachexia, anxiety and fear can all contribute. A cycle of panic and breathlessness, often associated with fear of dying, can be dominant. Exploration of precipitating factors is important and patient education about breathlessness and effective breathing has been shown to be effective. Non-pharmacological approaches that include using a hand-held fan, pacing and following a tailored exercise programme can help. There is no evidence to suggest that oxygen therapy reduces the sensation of breathlessness in advanced cancer any better than cool airflow, and oxygen is indicated only if there is significant hypoxia. Opioids, through both their central and their peripheral action, can palliate breathlessness. Both oral and parenteral opioids are effective and are now licensed for this indication in Australia. A low dose should be used initially and titrated against symptoms, unless opioids are already being prescribed for pain, in which case the existing dose can be increased further. If anxiety is considered to be playing a significant role, a quick-acting benzodiazepine, such as lorazepam (used sublingually for rapid absorption), may also be useful.

### Cough

Persistent unproductive cough can be helped by opioids, which have an antitussive effect. Troublesome respiratory secretions can be treated with hyoscine hydrobromide (400–600 µg every 4–8 hours), although dry mouth is a common adverse effect. As an alternative, glycopyrronium can be useful and is given by subcutaneous infusion (0.6–1.2 mg in 24 hours).

**Fig. 8.10 Mechanisms of nausea.** (ACh = acetylcholine; D<sub>2</sub> = dopamine; 5-HT = 5-hydroxytryptamine, serotonin; H<sub>1</sub> = histamine)

## Nausea and vomiting

The presentation of nausea and vomiting differs depending on the underlying cause, of which there are many. Large-volume vomiting with little nausea is common in intestinal obstruction, whereas constant nausea with little or no vomiting is often due to metabolic abnormalities or adverse effects of drugs. Vomiting related to raised intracranial pressure is worse in the morning. Different receptors are activated, depending on the cause or causes of the nausea (Fig. 8.10). For example, dopamine receptors in the chemotactic trigger zone in the fourth ventricle are stimulated by metabolic and drug causes of nausea, whereas gastric irritation stimulates histamine receptors in the vomiting centre via the vagus nerve. Reversible causes, such as hypercalcaemia and constipation, should be treated appropriately. Drug-induced causes should be considered and the offending drugs stopped if possible. As different classes of antiemetic drug act at different receptors, antiemetic therapy should be based on a careful assessment of the probable causes and a rational decision to use a particular class of drug (Box 8.16). The subcutaneous route is often required initially to overcome gastric stasis and poor absorption of oral medicines.

## Gastrointestinal obstruction

Gastrointestinal obstruction is a frequent complication of intra-abdominal cancer. Patients may have multiple levels of obstruction and symptoms may vary greatly in nature and severity. Surgical mortality is high in patients with advanced disease and obstruction should normally be managed without surgery. The key to effective management is to address the presenting symptoms – colic, abdominal pain, nausea, vomiting, intestinal secretions – individually or in combination, using parenteral drugs that do not cause or worsen other symptoms. This can be problematic when a specific treatment worsens another symptom. Cyclizine improves nausea and colic responds well to anticholinergic agents, such

## 8.16 Receptor site activity of antiemetic drugs

Area	Receptors	Drugs
<b>Chemotactic trigger zone</b>	Dopamine <sub>2</sub> 5-HT	Haloperidol Metoclopramide
<b>Vomiting centre</b>	Histamine <sub>1</sub> Acetylcholine	Cyclizine Levomepromazine Hyoscine
<b>Gut (gastric stasis)</b>		Metoclopramide
<b>Gut distension (vagal stimulation)</b>	Histamine <sub>1</sub>	Cyclizine
<b>Gut (chemoreceptors)</b>	5-HT	Levomepromazine

(5-HT = 5-hydroxytryptamine, serotonin)

as hyoscine butylbromide, but both slow gut motility. Nausea will improve with metoclopramide, although this is usually contraindicated in the presence of colic because of its prokinetic effect. There is some low-quality evidence that glucocorticoids (dexamethasone 8 mg) can shorten the length of obstructive episodes. Somatostatin analogues, such as octreotide, will reduce intestinal secretions and therefore large-volume vomits. Occasionally, a nasogastric tube is required to reduce gaseous or fluid distension.

## Weight loss

Patients with cancer lose weight for a variety of reasons, including reduced appetite or the effects of drug treatment, or as a consequence of low mood and anxiety. There is, however, a particularly challenging syndrome associated with weight loss, which is known as cancer cachexia. This results from an alteration of metabolism caused by a complex interaction of tumour-related factors and the body's response to these factors, resulting in muscle loss, along with anorexia. Treatment involves prescribing exercise to maintain muscle mass and strengthen muscles, ensuring that there is an adequate calorie intake and providing nutritional supplements. Anti-inflammatory medication to attenuate systemic inflammation is the subject of research and many patients self-medicate with fish oil. Glucocorticoids can temporarily boost appetite and general well-being but may cause false weight gain by promoting fluid retention. Their benefits need to be weighed against the risk of side-effects, and glucocorticoids should generally be used on a short-term basis only.

## Anxiety and depression

Anxiety and depression are common in palliative care but the diagnosis may be difficult, since the physical symptoms of depression are similar to those of advanced cancer. It is therefore important to acknowledge that these symptoms are not inevitable in advanced cancer. Patients should still expect to look forward to things and to enjoy them, within the context of the situation. Simply asking the question 'Do you think you are depressed?' can be very useful in deciding with the patient whether antidepressants or psychological interventions may be of benefit. In this regard, psycho-oncology has been evolving rapidly and there is now good evidence for the role of 'talk therapy' in palliative care, along with other appropriate management of anxiety and depression. If antidepressants are required, citalopram and mirtazapine are good choices since they are generally well tolerated in patients with advanced disease.

## Delirium and agitation

Many patients become confused or agitated in the last days of life. It is important to identify and treat potentially reversible causes unless the patient is too close to death for this to be feasible. Early diagnosis and effective management of delirium are extremely important. As in

other palliative situations, it may not be possible to identify and treat the underlying cause, and the focus of management should be to ensure that the patient is comfortable. It is important to distinguish between behavioural change due to pain and that due to delirium, as opioids will improve one and worsen the other. The management of delirium is detailed in [Chapter 34](#). It is important, even in the care of the actively dying patient, to treat delirium with antipsychotic medicines, such as haloperidol, or olanzapine if under 70 years, rather than to regard it as distress or anxiety and use benzodiazepines only.

## Dehydration

Deciding whether to give intravenous fluids can be difficult when a patient is very unwell and the prognosis is uncertain. A patient with a major stroke, who is unable to swallow but is expected to survive the event, will develop renal impairment and thirst if not given fluids and should be hydrated. On the other hand, when a patient has been deteriorating and is clearly dying, parenteral hydration needs very careful consideration and it is very important to manage this on an individual basis. Patient comfort and avoidance of distress in the family are the primary aims. Where a patient and family are happy with meticulous oral hygiene and care to reduce the sensation of dryness in the mouth, this is usually more appropriate and effective at the end of life than parenteral hydration, which by itself will not necessarily improve the sensation of dryness. In some patients, parenteral hydration will simply exacerbate pooling of secretions, causing noisy and distressing breathing. Each decision should be individual and discussed with the patient's family.

## Death and dying

### Planning for dying

There have been dramatic improvements in the medical treatment and care of patients with cancer and other illnesses over recent years but the inescapable fact remains that everyone will die at some time. Planning for death should be actively considered in patients with chronic diseases when the death is considered to be foreseeable or inevitable. Doctors rarely know exactly when a patient will die but are usually aware that an individual is about to die and that medical interventions are unlikely to extend life or improve its quality significantly. Most people wish their doctors to be honest about this situation to allow them time to think ahead, make plans and address practical issues. A few do not wish to discuss future deterioration or death; if this is felt to be the case, avoidance of discussion should be respected. For doctors, it is helpful to understand an individual's wishes and values about medical interventions at this time, as this can help guide decisions about interventions. It is important to distinguish between interventions that will not provide clinical benefit (a medical decision) and those that do not confer sufficient benefit to be worthwhile (a decision that can only be reached with a patient's involvement and consent). A common example of this would be decisions about not attempting cardiopulmonary resuscitation.

In general, people wish for a dignified and peaceful death and most, but not all, prefer to die at home. Families also are grateful for the chance to prepare themselves for the death of a relative, by timely and gentle discussion with the doctor or other health professionals. Early discussion and effective planning improve the chances that an individual's wishes will be achieved. There are two important caveats: firstly, wishes can and do change as the terminal situation evolves, and secondly, planning in general can only be done over time as patients form a relationship with professionals and evolve an understanding of the situation in which they find themselves. Attempts to carry out and finalise advanced care planning at a single consultation, especially if a first meeting, are usually unsatisfactory.

Structures for assessment and planning around end-of-life care are for guidance only and the focus should evolve with the individual patient.

## Diagnosing dying

When patients with cancer or other conditions become bed-bound, semi-comatose, unable to take tablets and only able to take sips of water, with no reversible cause, they are likely to be dying and many will have died within 2 days. Doctors are sometimes poor at recognising this and should be alert to the views of other members of the multidisciplinary team. A clear decision that the patient is dying should be agreed and recorded.

## Management of dying

Once the conclusion has been reached that a patient is going to die in days to a few weeks, there is a significant shift in management ([Box 8.17](#)). Symptom control, relief of distress and care for the family become the most important elements of care. Medication and investigation are justifiable only if they contribute to these ends. When patients can no longer drink because they are dying, intravenous fluids are usually not necessary and may cause worsening of bronchial secretions; however, this is a decision that can be made only on an individual basis. Management should not be changed without discussion with the patient and/or family. Medicines should always be prescribed for the relief of symptoms. For example, morphine or diamorphine may be used to control pain, levomepromazine to control nausea, haloperidol to treat delirium, diazepam or midazolam to treat distress, and hyoscine hydrobromide to reduce respiratory secretions. Side-effects, such as drowsiness, may be acceptable if the principal aim of relieving distress is achieved. It is important to discuss and agree the aims of care with the patient's family. Poor communication with families at this time is one of the most common reasons for family distress afterwards and for formal complaints.

## Ethical considerations

The overwhelming force in caring for any patient must be to listen to that patient and family and take their wishes on board. Patients know

 <b>8.17 How to manage a patient who is dying</b>	
<b>Patient and family awareness</b>	<ul style="list-style-type: none"> <li>Assess patient's and family's awareness of the situation</li> <li>Ensure patient, if able, and family understand plan of care</li> </ul>
<b>Medical interventions</b>	<ul style="list-style-type: none"> <li>Stop non-essential medications that do not contribute to symptom control</li> <li>Stop inappropriate investigations and interventions, including routine observations</li> </ul>
<b>Resuscitation</b>	<ul style="list-style-type: none"> <li>Complete Do Not Attempt Cardiopulmonary Resuscitation (DNACPR) form</li> <li>Deactivate implantable defibrillator</li> </ul>
<b>Symptom control</b>	<ul style="list-style-type: none"> <li>Ensure availability of parenteral medication for symptom relief</li> </ul>
<b>Support for family</b>	<ul style="list-style-type: none"> <li>Make sure you have contact details for family, that you know when they want to be contacted and that they are aware of facilities available to them</li> </ul>
<b>Religious and spiritual needs</b>	<ul style="list-style-type: none"> <li>Make sure any particular wishes are identified and followed</li> </ul>
<b>Ongoing assessment</b>	<ul style="list-style-type: none"> <li>Family's awareness of condition</li> <li>Management of symptoms</li> <li>Need for parenteral hydration</li> </ul>
<b>Care after death</b>	<ul style="list-style-type: none"> <li>Make sure family know what they have to do</li> <li>Notify other appropriate health professionals</li> </ul>

when health-care professionals are just receiving the information, as opposed to receiving and understanding the information in the context of the patient, their illness and needs, their carers and the socioeconomic context. It is impossible to provide holistic care for a patient without this comprehension. Every patient is unique and it is important to avoid slipping into a tick-box mentality in addressing items that should be covered in patients with advanced, incurable disease. While the key to successful palliative care is effective interdisciplinary working, every patient needs to know who has overall responsibility for their care. Trust in the whole team will come through a solid lead working with a team who are appropriately informed and in sympathy with the patient's situation, each having a clear role.

Families and other carers are often unprepared for the challenge of caring for a dying person. It can be an exhausting experience, both emotionally and physically, and without a critical number of carers battle fatigue can ensue, resulting in urgent admissions. With much discussion about advance directives, we should not lose sight of the reality of changing circumstances and wishes. Good anticipatory care means not just providing for new physical symptoms, but also planning for any time when care at home becomes no longer possible.

### Capacity and advance directives

The wishes of the patient are paramount in Western societies, whereas in other cultures the views of the family are equally important. If a patient is unable to express their view because of communication or cognitive impairment, that person is said to lack 'capacity'. In order to decide what the patient would have wished, as much information as possible should be gained about any previously expressed wishes, along with the views of relatives and other health professionals. An advance directive is a previously recorded, written document of a patient's wishes. It should carry the same weight in decision-making as a patient's expressed wishes at that time, but may not be sufficiently specific to be used in a particular clinical situation. The legal framework for decision-making varies in different countries.

### Euthanasia

In the UK and Europe, between 3% and 6% of dying patients will ask a doctor to end their life. Many of these requests are transient; some are associated with poor control of physical symptoms or a depressive illness. All expressions of a wish to die are an opportunity to help the patient discuss and address unresolved issues and problems. Reversible causes, such as pain or depression, should be treated. Sometimes, patients may choose to discontinue life-prolonging treatments, such as diuretics or anticoagulation, following discussion and the provision of adequate alternative symptom control. However, there remain a small number of patients who have a sustained, competent wish to end their lives, despite good control of physical symptoms. Euthanasia is now permitted or legal under certain circumstances in some countries but remains illegal in many others; public, ethical and legal debate over this issue continues and is often influenced by many complex non-palliative

care issues. The European Association for Palliative Care does not see euthanasia or physician-assisted suicide as part of the role of palliative care physicians. The British Medical Association (BMA) has published results from its recent poll on assisted dying in the *BMJ* (8 October 2020). Respect for others' freedom is reflected in this poll as, even though 50% supported a change in the law to permit assisted dying, only 36% of those polled would be personally willing to prescribe lethal drugs. The results were similar for euthanasia, with 37% supporting a change in the law, but only 26% willing to participate in any way in the process of administering drugs with the intention of ending an eligible patient's life. It can be inferred from the poll, that although some BMA members would support a legal framework, thereby respecting freedom of opinion and demonstrating a toleration of others' views, the majority would not be prepared to be involved in assisted dying or in euthanasia themselves, even if legal (see 'Further information').

## Multiple Choice Questions

8.1. A 45-year-old woman consults her GP with gradually worsening low back pain that started over 2 years ago. There is no radiation, nor any red flags. She can't take non-steroidal anti-inflammatory drugs (NSAIDs) due to gastrointestinal upset. She takes co-codamol 30/500, at a dose of 8 tablets per day, with limited benefit. She works as a cleaner in the local school and is a single parent, with three children ranging in age from 7 to 18. She has been off work for the last 6 months after a flare-up that has not settled, and is worried about her job and her finances. Her mother lives nearby and is very supportive, helping out with child care and shopping. She saw a physiotherapist for one session, but didn't go back as she felt the exercises were too hard and made the pain worse. She worries that if the pain gets worse she must be damaging her back, and she spends much of her time in bed or lying on the couch. What management approach should be used to increase her physical activity?

- A. Refer back to the physiotherapist for more effective exercises
- B. Prescribe stronger analgesics, such as morphine, to control the pain better, and thus allow her to do more.
- C. Assess what barriers there are to increasing her physical activity before agreeing on management
- D. Refer for further investigations, such as X-ray or magnetic resonance imaging (MRI), of her lumbar spine to exclude any sinister causes, such as malignancy, or to identify any surgical target
- E. Add in diazepam to help with muscle spasm and reduce her anxiety about the impact of the pain

Answer: C.

There is good evidence that increasing physical activity is an effective way to manage chronic pain, but it is acknowledged that there may be a number of barriers preventing people who live with chronic pain from doing this successfully. These can include fear avoidance, not pacing activities well, financial problems or other commitments that prevent their ability to attend appointments or go to a leisure centre. Advice alone is not enough and personal preference/previous experience will impact on patient engagement. There is no one type of exercise that will work for everyone (see Box 8.6). Strong opioids are not recommended for long-term use in chronic pain, and combining these with other sedative drugs may be harmful. There is no good evidence that benzodiazepines are helpful in chronic low back pain. Continued investigation in the absence of specific concerns is not recommended.

8.2. A 27-year-old man was involved in a severe road traffic accident, and suffered multiple lower limb fractures requiring orthopaedic intervention and several surgeries. His pain control was challenging whilst he was an in-patient, and he was discharged on oramorph 10–20 mg as required for pain, prescribed up to 6 times daily, plus MST 40 mg 2 times daily and paracetamol 1 g 4 times daily. The plan was that he would be reviewed in the orthopaedic clinic, but he defaulted from attending. He lived alone, with no family nearby or supportive friends. He attended his GP complaining of severe, poorly controlled pain, nightmares, flashbacks to the accident and with very poor sleep and low mood, to the extent that he felt that life was not worth living. He was asking for an increase in his oramorph to help him cope, as he had tried taking a higher dose (40 mg) and felt it was effective, especially in improving sleep. What would be the first step in your management plan?

- A. Increase his oramorph as a short-term solution in order to relieve distress and improve sleep

- B. Assess suicide risk and institute appropriate urgent support if required
- C. Refer back to the orthopaedic team for consideration of further investigations or surgery
- D. Add in anti-neuropathic agents, such as gabapentin, in case there is a neuropathic component to his pain
- E. Refer for assessment and management of possible post-traumatic stress disorder (PTSD) syndrome

Answer: B.

This is the most urgent action as he has a number of risk factors, including co-morbid mental health issues, high levels of distress, isolation, limited social support, being prescribed strong opioids and not using them according to prescribing advice. Suicide risk assessment should include risk factors, evidence of planning and means to carry it out, and protective factors. Further management depends on the degree and urgency of risk, ranging from urgent involvement of the duty mental health team to liaison with GP/other relevant health-care professionals and offering information on support available (local, telephone, online).

Increasing oramorph with the aim of improving sleep and/or mood would not be appropriate or safe (see Box 8.10). Similarly, adding in gabapentin may increase the risk of death, and further assessment of neuropathic features would be needed if being considered at a later date (see Fig. 8.7). Additionally, consideration should be given to using controlled dispensing arrangements to help improve safety (e.g. daily pick-up from the pharmacy). Further orthopaedic involvement and treatment of PTSD symptoms would be appropriate, but do not address the immediate problem.

8.3. John is a 73-year-old, retired joiner with a 3-month history of right-sided chest pain and cough. He has been receiving palliative radiotherapy for right-sided Pancoast's tumour. He lives with his wife, and his family are not nearby.

Timeline

1. John was reviewed during radiotherapy because of pain in his right shoulder and arm. He experiences constant severe background pain, rated as 9/10. He also experiences intermittent, excruciating shooting pain associated with pins and needles and a tight sensation, rated as 10/10.
2. John is unable to sleep. He says he feels miserable and hopeless, and that he 'doesn't look forward to anything, each day is a challenge'. He has also lost weight and has a poor appetite.
3. His medication is:

Co-codamol (30/500 mg) 2 tablets 4 times a day  
Laxidol (laxative) 1 sachet daily

4. He was able to give a clear history that a codeine and paracetamol combination worked within 40 minutes, but lasted for just an hour, reducing background pain from 10/10 to 8/10. John has normal biochemistry.

Which of the following did John's doctor suggest?

- A. Stop co-codamol and start titration with a strong opioid to 5 mg of normal release morphine orally 6 times daily, with the same dose provided for breakthrough analgesia (1/6 of the total 24-hour dose). Advice with regard to continuing with the laxative and a metoclopramide made available in case of nausea. Arranged a review in 48 hours
- B. As in answer A, but also continue with co-codamol
- C. His doctor was concerned about commencing a strong opioid too soon, as John was not yet actively dying. So, he decided to try tramadol instead of co-codamol.

- D. In view of John's mood and inability to sleep, analgesia should be left unchanged; however, night sedation and an antidepressant can be introduced
- E. The doctor knew it was important to control John's pain as quickly as possible, therefore slow-release morphine 60 mg 2 times daily was commenced

Answer: A.

Pain affects, and is affected by, many other symptoms and aspects of daily living. Time spent on the initial detailed assessment of all aspects of the patient is key to successful management. For John, rapid proposed solutions to his myriad of problems would only lead to therapeutic chaos. The key decision is what is the greatest driver of the symptoms and how does this potentially interact with other symptoms and distress.

Our patient had very severe pain with a strong neuropathic component, as would be expected from pressure on and/or invasion of the brachial plexus by the tumour. It is not surprising that he was not sleeping, because of this extremely severe pain, and felt thoroughly miserable and hopeless. His poor appetite and weight loss could be a result of the uncontrolled pain; however, it could also be the result of the cancer process via a cachexia mechanism. It is important to recognise that neuropathic pain is particularly associated with mood disturbances.

When assessing complexities, it is important to ground decisions on information obtained directly from the patient. John was able to give a clear history that a codeine and paracetamol combination worked within 40 minutes but lasted for just an hour, and the clue here is that his pain was at least partially opioid responsive. It is critical not to move sideways on an analgesic ladder and if maximum dose of codeine is not effective, the patient should move to a strong opioid, such as morphine. The usual starting dose in this situation of normal renal function and such severe pain should be 5 mg of normal release morphine orally 6 times daily. If starting modified-release morphine, the dose is 10–15 mg 2 times daily. For breakthrough analgesia the dose is usually 1/6 of the total 24-hour dose, so 5 mg in this case. The patient should be advised that if breakthrough pain relief is required it will take 30 minutes to start having an effect. The patient should be instructed to take a careful note of duration onset and duration of effect of the regular dose, and frequency of onset and duration and effect of the breakthrough dose.

- 8.4. On review after 48 hours, John reported that his background pain reduced from 9/10 to 4/10 within 40 minutes of taking 5 mg of normal-release morphine. The improvement lasted for 2 hours,

after which background pain returned to 9/10. A breakthrough dose of 5 mg immediate-release morphine then reduced background pain to 4/10 again and this lasted for another 2 hours. In total 5 regular doses and 6 breakthrough doses of 5 mg normal-release morphine were used in 24 hours.

Crucially, there was no sedation, sleepiness or vivid dreams. Bowels were moving normally with the laxative prescribed and no nausea was present.

The severe, intermittent, shooting pain was less frequent and reduced from 10/10 to 5/10.

Sleep, appetite, mood and interactions with others were much improved.

What did John's doctor decide to do next?

- A. Switch to slow-release morphine, 15 mg 2 times daily and continue to encourage use of breakthrough analgesia with 5 mg normal release morphine as required
- B. As A, but also add in amitriptyline 10 mg at bedtime
- C. Continue on normal-release morphine 5 mg 6 times daily and increase breakthrough to 10 mg normal release morphine as required and review in 48 hours
- D. Switch to slow-release morphine, 30 mg 2 times daily and prescribe normal-release morphine 10 mg for breakthrough pain
- E. No changes to opioid regimen, but add dexamethasone for brachial plexus pressure, appetite and general wellbeing

Answer: D.

The strong history provided by John is of an opioid-responsive pain. It is clear that a dose of 10 mg 6 times daily would bring background pain from 9/10 to 4/10. At present there are no opioid-related side effects, therefore a switch to a sustained-release morphine of 30 mg 2 times daily is reasonable, instead of 10 mg normal-release 6 times daily. Breakthrough normal-release morphine should be increased to 10 mg and used as required. Ongoing review of common opioid side effects is crucial.

On further review of pain relief, breakthrough opioid required, intermittent component of pain and other symptoms, such as mood, appetite and weight, may lead to further manipulation of John's management at follow-up.

## Clinical examination in critical care

### A Airway

Is the airway patent?  
Is the end-tidal CO<sub>2</sub> trace normal?  
Are there any signs of airway obstruction?

### I Infection

What is the temperature?  
Review recent infective markers and trend  
What antibiotics are being given and what is the duration of treatment?

### H Haematology

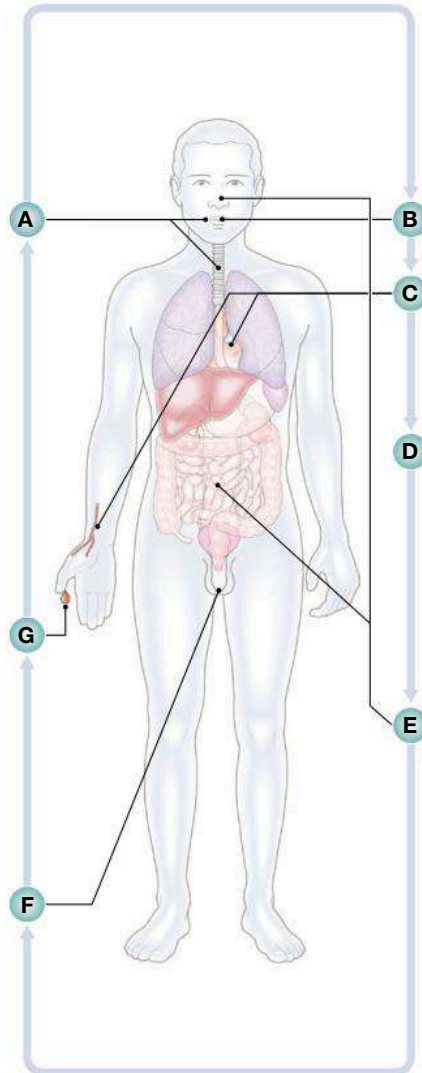

What are the haemoglobin/platelet levels?  
Are there any signs of bleeding?

### G Glucose

What is the glucose level?  
Is insulin being administered?

### F Fluids, electrolytes and renal system

What is the fluid balance?  
Urine volume and colour?  
Is there any oedema?  
Review the renal biochemistry and electrolyte levels

### E Enteral/exposure

Feeding regimen  
Stool frequency  
Abdominal tenderness/bowel sounds present?

### B Breathing

Is the physiology normal (SpO<sub>2</sub>, respiratory rate, tidal volume)?  
What is the level of support?  
Are there any abnormal signs on chest examination?  
Review the ventilator settings, arterial blood gases and recent chest X-ray

### C Circulation

Is the physiology normal (heart rate, blood pressure, peripheral temperature, lactate, urine output)?  
How much support is required (inotrope, vasopressor)?

### D Disability

Level of responsiveness  
Delirium screen  
Pupillary responses  
Doses of sedative drugs

## Monitoring

**Electrocardiography**

Heart rate, rhythm and QRS morphology

**Arterial line trace**

Size of the area under the curve is proportional to stroke volume  
Narrow peaks suggest low stroke volume as shown here

**Oxygen saturation**

Saturation of haemoglobin measured by plethysmography ( $SpO_2$ ). Gives an indication of adequacy of oxygenation, and the quality of tissue perfusion can also be inferred – a flat trace suggests poor peripheral perfusion

**Central venous pressure trace**

A non-specific guide to volume status and right ventricular function. Increased values in fluid overload and right ventricular failure

**Capnography**

Numerical value of end-tidal  $CO_2$  ( $ETCO_2$ ) is less than arterial  $PCO_2$  ( $PaCO_2$ ) by a variable amount. Shape of trace can signify airway displacement/obstruction, bronchospasm or a low cardiac output (as shown below)

Beside physiological data commonly monitored in an intensive care unit setting.

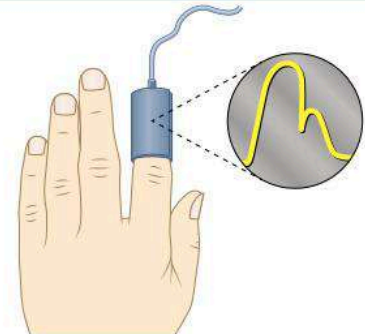

## i

**Pulse oximetry ( $SpO_2$ )****Basic principles**

- Uses the different red and infrared absorption profiles of oxyhaemoglobin and deoxyhaemoglobin to estimate arterial oxyhaemoglobin saturation ( $SaO_2$ )
- Only pulsatile absorption is measured
- A poor trace correlates with poor perfusion

**Sources of error**

- Carboxyhaemoglobin – absorption profile is the same as oxyhaemoglobin: falsely elevated  $SpO_2$
- Methaemoglobinaemia –  $SpO_2$  will tend towards 85%
- Ambient light/poor application of probe/severe tricuspid regurgitation (pulsatile venous flow): falsely depressed  $SpO_2$
- Reduced accuracy below 80% saturation
- Hyperbilirubinaemia does not affect  $SpO_2$

Hospital medicine is becoming ever-more specialised and people are living longer while accruing increasing numbers of chronic disease diagnoses. Rather than diminishing the role of the generalist, these factors paradoxically create a need for experts in the undifferentiated presentation. In the UK such physicians are known as 'general physicians', while in the United States they are referred to as 'hospitalists'.

Acute illness can present in a large variety of ways, depending on the nature of the illness, the underlying health of the individual, and their cultural and religious background. The skills of prompt diagnosis formation and provision of appropriate treatment rely on the integration of information from all the available sources, along with careful consideration of underlying chronic health problems.

Patients who deteriorate while in hospital make up a small but important cohort. If they are well managed, in-hospital cardiac arrest rates will be low. This can be achieved through the combined effects of prompt resuscitation and appropriate end-of-life decision-making. Early recognition of deterioration by ward teams and initial management by health-care professionals operating within a functioning rapid response system are the central tenets of any system designed to improve the outcomes of deteriorating ward patients.

Intensive care medicine has developed into a prominent specialty, central to the safe functioning of a modern acute hospital. Scientific endeavour has resulted in a much better understanding of the molecular pathophysiology of processes such as sepsis and acute respiratory distress syndrome, which account for much premature death worldwide.

## Acute medicine

Acute medicine is the part of general medicine that is concerned with the immediate and early management of medical patients who require urgent care. As a specialty, it is closely aligned with emergency medicine and intensive care medicine, but is firmly rooted within general medicine. Acute physicians manage the adult medical take and lead the development of acute care pathways that aim to reduce variability, improve care and cut down hospital admissions. In order to achieve these aims, acute physicians must use their knowledge, combined with high-level clinical reasoning and decision-making skills, to minimise both diagnostic error and the risks of over-investigation. These concepts are explained more fully in [Chapter 1](#).

### The decision to admit to hospital

Every patient presenting to hospital should be assessed by a clinician who is able to determine whether or not admission is required. The requirement for admission is determined by many factors, including the severity of illness, the patient's physiological reserve, the need for urgent investigations, the nature of proposed treatments and the patient's social circumstances. In many cases, it is clear early in the assessment process

that a patient requires admission. In such cases, a move into a medical receiving unit – often termed a medical admissions unit (MAU) or acute medical unit (AMU) – should be facilitated as soon as the initial assessment has been completed and urgent investigations and/or treatments have been instigated. In hospitals where such units do not exist, patients will need to be moved to a downstream ward once treatment has been commenced and they have been deemed sufficiently stable. In suspected cases of airborne-transmissible infectious diseases, patients should be isolated initially and may require cohorting in specific areas of the hospital once diagnoses have been confirmed. Following the initial assessment, it may be possible to discharge stable patients home with a plan for early follow-up (such as a rapid-access specialist clinic appointment).

## Ambulatory care

In some hospitals, it is increasingly possible for patient care to be coordinated in an ambulatory setting, negating the need for a patient to remain in hospital overnight. In the context of acute medicine, ambulatory care can be employed for conditions that are perceived by either the patient or the referring practitioner as requiring prompt clinical assessment by a competent decision-maker with access to appropriate diagnostic resources. The patient may return on several occasions for investigation, observation, consultation or treatment. Some presentations, such as a unilateral swollen leg (p. 188), lend themselves to this type of management ([Box 9.1](#)). If indicated, a Doppler ultrasound can be arranged, and patients with confirmed deep vein thrombosis can be anticoagulated on an outpatient basis. Successful ambulatory care requires careful patient selection; while many patients may cherish the opportunity to sleep at home, others may find frequent trips to hospital or clinic too difficult due to frailty, poor mobility or transport difficulties.

## Presenting problems in acute medicine

This section details some of the most common presentations to acute medicine. However, many people present to hospital with physical complaints that do not appear to be the symptoms of a medical condition, referred to as 'medically unexplained' or 'functional' symptoms (see [Chs 23, 28 and 31](#)). It is thought that such symptoms may account for up to half of all new visits to hospital in the UK. Rather than providing reassurance, a lack of understanding of the cause of the symptoms can result in more distress for patients. When the unexplained symptoms relate to the nervous system (such as limb weakness, numbness, shaking or black-outs), the term 'functional neurological disorder' is used (see p. 1152). Medically unexplained symptoms are more common in women, younger people, those who have previously suffered from depression or anxiety, recently bereaved people and those recovering from a recent physical

### i 9.1 Groups of patients who are potentially suitable for ambulatory care

Group	Example(s)	Quality and safety issues
<b>Diagnostic exclusion group</b>	Chest pain – possible myocardial infarction; breathlessness – possible pulmonary embolism	Even when a specific condition has been excluded, there is still a need to explain the patient's symptoms through the diagnostic process
<b>Low-risk stratification group</b>	Non-variceal upper gastrointestinal bleed with low Blatchford score ( <a href="#">Box 23.16</a> ); community-acquired pneumonia with low CURB-65 score (see <a href="#">Fig. 17.32</a> )	Appropriate treatment plans should be in place
<b>Specific procedure group</b>	Replacement of percutaneous endoscopic gastrostomy (PEG) tube; drainage of pleural effusion/ascites	The key to implementation is how ambulatory care for this group of patients can be delivered when they present out of hours
<b>Outpatient group with supporting infrastructure</b>	Deep vein thrombosis (DVT); cellulitis	These are distinct from the conditions listed above because the infrastructure required to manage them is quite different

illness. For every acute medical presentation, there will be a cohort of patients for whom the diagnosis remains elusive. In such circumstances, consideration should be given to the potential harm of over-investigation and the alternative approaches required to manage medically unexplained symptoms. Further detail can be found on p. 1256.

## Chest pain

Chest pain is a common symptom in patients presenting to hospital. The differential diagnosis is wide (Box 9.2), and a detailed history and thorough clinical examination are paramount to ensure that the subsequent investigative pathway is appropriate.

### Presentation

Chest 'pain' is clearly a subjective phenomenon and may be described by patients in a variety of different ways. Whether the patient describes 'pain', 'discomfort' or 'pressure' in the chest, there are some key features that must be elicited from the history.

### Site and radiation

Pain secondary to myocardial ischaemia is typically located in the centre of the chest. It may radiate to the neck, jaw and upper or even lower arms. Occasionally, it may be experienced only at the sites of radiation or in the back. The pain of myocarditis or pericarditis is characteristically felt retrosternally, to the left of the sternum, or in the left or right shoulder. The severe pain of aortic dissection is typically central with radiation through to the back. Central chest pain may also occur with tumours affecting the mediastinum, oesophageal disease (p. 806) or disease of the thoracic aorta (p. 342). Pain situated over the left anterior chest and radiating

laterally is unlikely to be due to cardiac ischaemia and may have many causes, including pleural or lung disorders, musculoskeletal problems or anxiety. Rarely, sharp, left-sided chest pain that is suggestive of a musculoskeletal problem may be a feature of mitral valve prolapse (p. 455).

### Characteristics

Pleurisy, a sharp or 'catching' chest pain aggravated by deep breathing or coughing, is indicative of respiratory pathology, particularly pulmonary infection or infarction. However, the pain associated with myocarditis or pericarditis is often also described as 'sharp' and may 'catch' during inspiration, coughing or lying flat. It typically varies in intensity with movement and the phase of respiration. A malignant tumour invading the chest wall or ribs can cause gnawing, continuous local pain. The pain of myocardial ischaemia is typically dull, constricting, choking or 'heavy', and is usually described as squeezing, crushing, burning or aching. Patients often emphasise that it is a discomfort rather than a pain. Angina occurs during (not after) exertion and is promptly relieved (in less than 5 minutes) by rest. It may also be precipitated or exacerbated by emotion but tends to occur more readily during exertion, after a large meal or in a cold wind. In crescendo or unstable angina, similar pain may be precipitated by minimal exertion or at rest. The increase in venous return or preload induced by lying down may also be sufficient to provoke pain in vulnerable patients (decubitus angina). Patients with reversible airways obstruction, such as asthma, may also describe exertional chest tightness that is relieved by rest. This may be difficult to distinguish from myocardial ischaemia. Bronchospasm may be associated with wheeze, atopy and cough (p. 489). Musculoskeletal chest pain is variable in site and intensity but does not usually fall into any of the patterns described above. The pain may vary with posture or movement of the upper body, or be associated with a specific movement (bending, stretching, turning). Many minor soft tissue injuries are related to everyday activities, such as driving, manual work and sport.

### Onset

The pain associated with myocardial infarction (MI) typically takes several minutes or even longer to develop to its maximal intensity; similarly, angina builds up gradually in proportion to the intensity of exertion. Pain that occurs after, rather than during, exertion is usually musculoskeletal or psychological in origin. The pain of aortic dissection (severe and 'tearing'), massive pulmonary embolism (PE) or pneumothorax is usually very sudden in onset. Other causes of chest pain tend to develop more gradually, over hours or even days.

### Associated features

The pain of MI, massive PE or aortic dissection is often accompanied by autonomic disturbance, including sweating, nausea and vomiting. Some patients describe a feeling of impending death, referred to as 'angor animi'. Breathlessness, due to pulmonary congestion arising from transient ischaemic left ventricular dysfunction, is often a prominent feature of myocardial ischaemia. Breathlessness may also accompany any of the respiratory causes of chest pain and can be associated with cough, wheeze or other respiratory symptoms. Patients with myocarditis or pericarditis may describe a prodromal viral illness. Gastrointestinal disorders, such as gastro-oesophageal reflux or peptic ulceration, may present with chest pain that is hard to distinguish from myocardial ischaemia; it may even be precipitated by exercise and be relieved by nitrates. However, it is usually possible to elicit a history relating chest pain to supine posture or eating, drinking or oesophageal reflux. The pain of gastro-oesophageal reflux often radiates to the interscapular region and dysphagia may be present. Severe chest pain arising after retching or vomiting, or following oesophageal instrumentation, should raise the possibility of oesophageal perforation.

Anxiety-induced chest pain may be associated with breathlessness (without hypoxaemia), throat tightness, perioral tingling and other evidence of emotional distress. It is important to remember, however, that chest pain itself can be an extremely frightening experience, and so psychological and organic features often coexist. Anxiety may amplify the effects of organic disease and a confusing clinical picture may result.

## 9.2 Differential diagnosis of chest pain

### Central

#### Cardiac

- Myocardial ischaemia (angina)
- Myocardial infarction
- Myocarditis
- Pericarditis
- Mitral valve prolapse syndrome

#### Aortic

- Aortic dissection
- Aortic aneurysm

#### Oesophageal

- Oesophagitis
- Oesophageal spasm
- Mallory–Weiss syndrome
- Oesophageal perforation (Boerhaave syndrome)

#### Pulmonary embolus

#### Mediastinal

- Malignancy

#### Anxiety/emotion<sup>1</sup>

### Peripheral

#### Lungs/pleura

- Pulmonary infarct
- Pneumonia
- Pneumothorax
- Malignancy
- Tuberculosis
- Connective tissue disorders

#### Musculoskeletal<sup>2</sup>

- Osteoarthritis
- Rib fracture/injury
- Acute vertebral fracture
- Costochondritis (Tietze syndrome)
- Intercostal muscle injury
- Epidemic myalgia (Bornholm disease)

#### Neurological

- Prolapsed intervertebral disc
- Herpes zoster

<sup>1</sup>May also cause peripheral chest pain. <sup>2</sup>Can sometimes cause central chest pain.

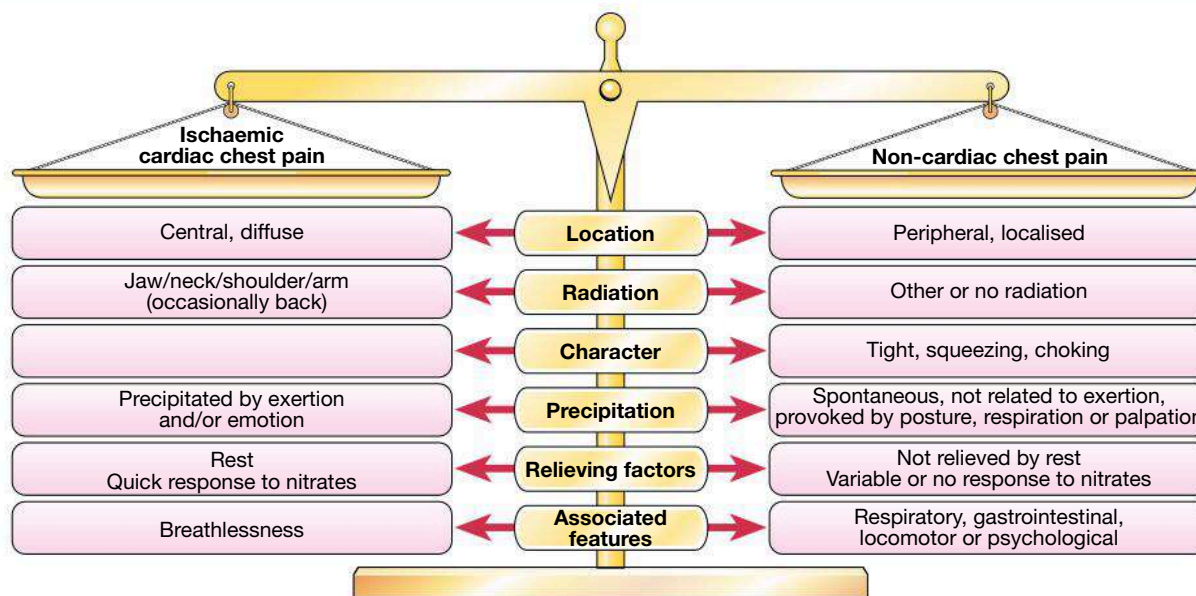

Fig. 9.1 Identifying ischaemic cardiac pain: the 'balance' of evidence.

A detailed and clear history is key to narrowing the differential diagnosis of chest pain. Figure 9.1 shows how certain features of the history, particularly when combined, can tip the balance of evidence towards or away from ischaemic cardiac chest pain.

### Clinical assessment

Cardiorespiratory examination may detect clinical signs that help guide ongoing investigation. Patients with a history compatible with myocardial ischaemia should have a 12-lead electrocardiogram (ECG) performed while clinical examination proceeds. Ongoing chest pain with clinical features of shock or pulmonary oedema, or ECG evidence of ventricular arrhythmia or complete heart block, should prompt urgent cardiology review and referral to a higher level of care.

Chest pain that is accompanied by clinical evidence of increased intracardiac pressure (especially a raised jugular venous pressure) increases the likelihood of myocardial ischaemia or massive PE. The legs should be examined for clinical evidence of deep vein thrombosis.

A large pneumothorax should be evident on clinical examination, with absent breath sounds and a hyper-resonant percussion note on the affected side. Other unilateral chest signs, such as bronchial breathing or crackles, are most likely to indicate a respiratory tract infection, and a chest X-ray should be expedited.

Pericarditis may be accompanied by a pericardial friction rub. In aortic dissection, syncope or neurological deficit may occur. Examination may reveal asymmetrical pulses, features of undiagnosed Marfan syndrome (p. 445) or a new early diastolic murmur representing aortic regurgitation.

Any disease process involving the pleura may restrict rib movement and a pleural rub may be audible on the affected side. Local tenderness of the chest wall is likely to indicate musculoskeletal pain but can also be found in pulmonary infarction.

Subdiaphragmatic inflammatory pathology, such as a liver abscess, cholecystitis or ascending cholangitis, can mimic pneumonia by causing fever, pleuritic chest pain and a small sympathetic pleural effusion, usually on the right. Likewise, acute pancreatitis can present with thoracic symptoms, and an amylase or lipase level should be requested where appropriate. It is imperative that the abdomen is examined routinely in all patients presenting with pleuritic chest pain.

### Initial investigations

Chest X-ray, ECG and biomarkers (e.g. troponin, D-dimer) play a pivotal role in the evaluation of chest pain. However, indiscriminate ordering of such investigations may result in diagnostic confusion and

over-investigation. The choice of investigation(s) is intimately linked to the history and examination findings. A chest X-ray and 12-lead ECG should be performed in the vast majority of patients presenting to hospital with chest pain. Pregnancy is not a contraindication to chest X-ray, but particular consideration should be given to whether the additional diagnostic information justifies breast irradiation.

The chest X-ray may confirm the suspected diagnosis, particularly in the case of pneumonia. Small pneumothoraces are easily missed, as are rib fractures or small metastatic deposits, and all should be considered individually during chest X-ray review. A widened mediastinum suggests acute aortic dissection but a normal chest X-ray does not exclude the diagnosis. Provided it has been more than 1 hour since the onset of pain, chest X-ray in oesophageal rupture may reveal subcutaneous emphysema, pneumomediastinum or a pleural effusion.

Patients with a history compatible with myocardial ischaemia require an urgent 12-lead ECG. Acute chest pain with ECG changes indicating a ST segment elevation myocardial infarction (STEMI) suggests that the patient is likely to benefit from immediate reperfusion therapy. Specific information relating to cocaine or amphetamine use should be sought, particularly in younger patients. In the context of a compatible history, an ECG showing ischaemic changes that do not meet STEMI criteria should prompt regular repeat ECGs and treatment for non-ST segment elevation myocardial infarction (NSTEMI)/unstable angina. Measurement of serum troponin concentration on admission is often helpful in cases where there is diagnostic doubt, but a negative result should always prompt a repeat sample 6–12 hours after maximal pain. Acute coronary syndrome may be diagnosed with confidence in patients with a convincing history of ischaemic pain (see Fig. 9.1) and either ECG evidence of ischaemia or an elevated serum troponin. If an elevated serum troponin is found in a patient who has an atypical history or is at low risk of ischaemic heart disease, then alternative causes of raised troponin should be considered (Box 9.3). Further management of acute coronary syndromes is discussed on page 432.

In the absence of convincing ECG evidence of myocardial ischaemia, other life-threatening causes of chest pain, such as aortic dissection, massive PE and oesophageal rupture, should be considered. Suspicion of aortic dissection (background of hypertension, trauma, pregnancy or previous aortic surgery) should prompt urgent thoracic computed tomography (CT) or transoesophageal echocardiography. An ECG in the context of massive PE most commonly reveals only a sinus tachycardia, but may show new right axis deviation, right bundle branch block or a dominant R wave in  $V_1$ . The classical finding of  $S_1Q_3T_3$  (a deep S wave in

### 9.3 Causes of elevated serum troponin other than acute coronary syndrome

#### Cardiorespiratory causes

- Pulmonary embolism
- Acute pulmonary oedema
- Tachyarrhythmias
- Myocarditis/myopericarditis
- Aortic dissection
- Cardiac trauma
- Cardiac surgery/ablation

#### Non-cardiorespiratory causes

- Prolonged hypotension
- Severe sepsis
- Severe burns
- Stroke
- Subarachnoid haemorrhage
- End-stage renal failure

lead I, with a Q wave and T wave inversion in lead III) is rare. If massive PE is suspected and the patient is haemodynamically unstable, a transthoracic echocardiogram, to seek evidence of right heart strain and exclude alternative diagnoses such as tamponade, is extremely useful.

If the patient is deemed to be at low risk of PE, a D-dimer test can be informative, as a negative result effectively excludes the diagnosis. The D-dimer test should be performed only if there is clinical suspicion of PE, as false-positive results can lead to unnecessary investigations. If the D-dimer is positive, there is high clinical suspicion, or there is other convincing evidence of PE (such as features of right heart strain on the ECG), prompt imaging should be arranged (p. 546 and Fig. 17.67).

## Acute breathlessness

In acute breathlessness, the history, along with a rapid but careful examination, will usually suggest a diagnosis that can be confirmed by routine investigations including chest X-ray, 12-lead ECG and arterial blood gas (ABG) sampling.

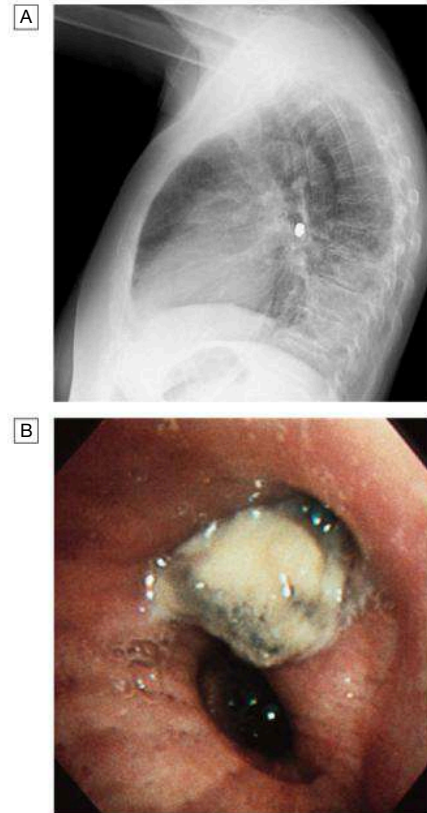

### Presentation

A key feature of the history is the speed of onset of breathlessness. Acute severe breathlessness (over minutes or hours) has a distinct differential diagnosis list to chronic exertional breathlessness. The presence of associated cardiovascular (chest pain, palpitations, sweating and nausea) or respiratory (cough, wheeze, haemoptysis, stridor) symptoms can narrow the differential diagnosis yet further. A previous history of left ventricular dysfunction, asthma or exacerbations of chronic obstructive pulmonary disease (COPD) is important. A high temperature, cough (productive or non-productive) and/or viral prodrome may indicate respiratory infection and, if so, relevant infection control precautions should be taken from initial assessment. In the severely ill patient, it may be necessary to obtain the history from accompanying witnesses. In children, the possibility of inhalation of a foreign body (Fig. 9.2) or acute epiglottitis should always be considered. There is often more than one underlying diagnosis; a thorough assessment should continue, even after a possible diagnosis has been reached, particularly if the severity of symptoms does not seem to be adequately explained. The causes of acute severe breathlessness are covered here; chronic exertional dyspnoea is discussed further on page 489.

### Clinical assessment

Airway obstruction, anaphylaxis and tension pneumothorax require immediate identification and treatment. If any of these is suspected, treatment should not be delayed while additional investigations are performed, and anaesthetic support is likely to be required. In the absence of an immediately life-threatening cause, the following should be assessed and documented:

- level of consciousness
- degree of central cyanosis
- work of breathing (rate, depth, pattern, use of accessory muscles)
- adequacy of oxygenation ( $SpO_2$ )

**Fig. 9.2 Inhaled foreign body.** **A** Chest X-ray showing a tooth lodged in a main bronchus. **B** Bronchoscopic appearance of inhaled foreign body (tooth) with a covering mucous film.

- ability to speak (in single words or sentences)
- cardiovascular status (heart rate and rhythm, blood pressure (BP) and peripheral perfusion).

Pulmonary oedema is suggested by a raised jugular venous pressure and bi-basal crackles or diffuse wheeze, while asthma or COPD is characterised by wheeze and prolonged expiration. A hyper-resonant hemithorax with absent breath sounds raises the possibility of pneumothorax, while severe breathlessness with normal breath sounds may indicate PE. Leg swelling may suggest cardiac failure or, if asymmetrical, venous thrombosis.

The presence of wheeze is not always indicative of bronchospasm. In acute left heart failure, an increase in the left ventricular diastolic pressure causes the pressure in the left atrium, pulmonary veins and pulmonary capillaries to rise. When the hydrostatic pressure of the pulmonary capillaries exceeds the oncotic pressure of plasma (about 25–30 mmHg), fluid moves from the capillaries into the interstitium. This stimulates respiration through a series of autonomic reflexes, producing rapid, shallow respiration, and congestion of the bronchial mucosa may cause wheeze (sometimes known as cardiac asthma). Sitting upright or standing may provide some relief by helping to reduce congestion at the apices of the lungs. The patient may be unable to speak and is typically distressed, agitated, sweaty and pale. Respiration is rapid, with recruitment of accessory muscles, coughing and wheezing. Sputum may be profuse, frothy and blood-streaked or pink. Extensive crepitations and rhonchi are usually audible in the chest and there may also be signs of right heart failure.

Any arrhythmia may cause breathlessness, but usually does so only if the heart is structurally abnormal, such as with the onset of atrial fibrillation in a patient with mitral stenosis. In such cases, the classic mid-diastolic rumbling murmur may be heard. Patients sometimes describe chest tightness as 'breathlessness'. However, myocardial ischaemia may also induce true breathlessness by provoking transient left ventricular dysfunction. When breathlessness is the dominant or sole feature of

myocardial ischaemia, it is known as 'angina equivalent'. A history of chest tightness or close correlation with exercise should be sought.

### Initial investigations

As shown in Box 9.4, amalgamation of a clear history and thorough clinical examination with chest X-ray, ECG and ABG findings will usually indicate the primary cause of breathlessness. In cases of suspected infection, a viral throat swab should be obtained early in the course of the assessment; increasingly point-of-care testing of viral throat swabs is available, providing important and rapid diagnostic information. If available, sputum should be sent for culture. If bronchospasm is suspected, measurement of peak expiratory flow will assist in the assessment of severity and should be performed whenever possible.

An ABG will often provide additional information to  $SpO_2$  measurement alone, particularly if there is clinical evidence (drowsiness, delirium, asterixis) or a strong likelihood of hypercapnia. An acute rise in  $PaCO_2$  will increase the  $HCO_3^-$  by only a small amount, resulting in inadequate buffering and acidaemia. Renal compensation and a large rise in  $HCO_3^-$  will take at least 12 hours. In acute type II respiratory failure (p. 496), the rate of rise of  $PaCO_2$  is a better indicator of severity than the absolute value. An ABG can also give a carboxyhaemoglobin level after smoke inhalation (although this can also be measured on a venous sample), and is central to the identification of metabolic acidosis or the diagnosis of psychogenic hyperventilation (see Box 9.4).

If pulmonary embolism is suspected, calculating pre-test probability (Ch. 1) is key. In a patient with a pre-test probability of less than 15%, the pulmonary embolism rule-out criteria (PERC) can rule out pulmonary embolism clinically, negating the need for further imaging, if none of the criteria listed in Box 9.5 is met. Further detail on the investigation and management of pulmonary embolus is given on page 546.

Procalcitonin (PCT) and N-terminal pro-hormone brain natriuretic protein (NT-proBNP) can be measured in venous blood. While these biomarkers can give an indication of aetiology in shortness of breath, they

are probably of more value in tracking clinical progression and response to treatment. Elevated PCT is a biomarker for bacterial infection and may be useful, in addition to clinical assessment, in helping decide the need for and duration of antibiotic therapy in patients with confirmed viral respiratory disease (such as COVID-19) who may have additional bacterial super-infection. Elevated NT-proBNP is suggestive of underlying left ventricular failure (p. 393), although it can be elevated in other conditions such as renal failure, COPD, pulmonary hypertension and pulmonary embolism. Measurement of NT-proBNP may be considered if there is no clear-cut evidence of pulmonary oedema on a chest X-ray and can be particularly useful as a 'rule-out' test, as a normal NT-proBNP has high negative predictive value for heart failure. Individuals with suspected heart failure should undergo early echocardiography (p. 402).

CT imaging (with or without pulmonary angiography) is a useful investigation in many respiratory conditions as interstitial changes, tumours or consolidation may not be evident on chest X-ray. If breathlessness is suspected to be an 'angina equivalent', objective evidence

### 9.5 PERC rule for pulmonary embolism

**Rules out PE if none of the eight criteria is present and pre-test probability is less than or equal to 15%** (1.8% was chosen as the point of equipoise between the benefits and risks of further investigations for PE, and the benefits and risks of *not* investigating further).

- Age  $\geq 50$
- Heart rate  $\geq 100$
- Oxygen saturation on room air  $< 95\%$
- Unilateral leg swelling
- Haemoptysis
- Recent surgery or trauma ( $\leq 4$  weeks ago requiring hospitalisation)
- Prior venous thromboembolism (VTE)
- Hormone use (oral contraceptives), hormone replacement or oestrogenic hormone use in male or female patients

### 9.4 Clinical features in acute breathlessness

Condition	History	Signs	Chest X-ray	ABG	ECG
<b>Pulmonary oedema</b>	Chest pain, palpitations, orthopnoea, cardiac history*	Central cyanosis, $\uparrow$ JVP, sweating, cool extremities, basal crackles*	Cardiomegaly, oedema/pleural effusions*	$\downarrow PaO_2$ $\downarrow PaCO_2$	Sinus tachycardia, ischaemia*, arrhythmia
<b>Massive pulmonary embolus</b>	Risk factors, chest pain, pleurisy, syncope*, dizziness*	Central cyanosis, $\uparrow$ JVP*, absence of signs in the lung*, shock (tachycardia, hypotension)	Often normal Prominent hilar vessels, oligoemic lung fields*	$\downarrow PaO_2$ $\downarrow PaCO_2$	Sinus tachycardia, RBBB, $S_1Q_3T_3$ pattern $\uparrow T(V_1-V_4)$
<b>Acute severe asthma</b>	History of asthma, asthma medications, wheeze*	Tachycardia, pulsus paradoxus, cyanosis (late), $\rightarrow$ JVP*, $\downarrow$ peak flow, wheeze*	Hyperinflation only (unless complicated by pneumothorax)*	$\downarrow PaO_2$ Normal $PaCO_2$ ( $\uparrow PaCO_2$ in extremis)	Sinus tachycardia (bradycardia in extremis)
<b>Acute exacerbation of COPD</b>	Previous episodes*, smoker. If in type II respiratory failure, may be drowsy	Cyanosis, hyperinflation*, signs of $CO_2$ retention (flapping tremor, bounding pulses)*	Hyperinflation*, bullae, complicating pneumothorax	$\downarrow$ or $\downarrow\downarrow PaO_2$ $\uparrow PaCO_2$ in type II failure $\pm \uparrow H^+$ , $\uparrow HCO_3^-$ in chronic type II failure	Normal, or signs of right ventricular strain
<b>Pneumonia/lower respiratory tract infection</b>	Prodromal illness*, fever*, rigors*, pleurisy*	Fever, delirium, pleural rub*, consolidation*, cyanosis (if severe)	Pneumonic consolidation*	$\downarrow PaO_2$ $\downarrow PaCO_2$ ( $\uparrow$ in extremis)	Tachycardia
<b>Metabolic acidosis</b>	Evidence of diabetes mellitus or renal disease, aspirin or ethylene glycol overdose	Fetor (ketones), hyperventilation without heart or lung signs*, dehydration*, air hunger	Normal	$PaO_2$ normal $\downarrow\downarrow PaCO_2$ , $\uparrow H^+$ $\downarrow HCO_3^-$	
<b>Psychogenic</b>	Previous episodes, digital or perioral dysaesthesia	No cyanosis, no heart or lung signs, carpopedal spasm	Normal	$PaO_2$ normal* $\downarrow\downarrow PaCO_2$ , $\downarrow H^+$ *	

\*Valuable discriminatory feature.

(ABG = arterial blood gas; COPD = chronic obstructive pulmonary disease; JVP = jugular venous pressure; RBBB = right bundle branch block)

of myocardial ischaemia from stress testing may help to establish the diagnosis, although coronary artery angiography (either by CT or cardiac catheterisation) is often performed early in the investigation pathway (p. 432).

## Anaphylaxis

Anaphylaxis is a potentially life-threatening, systemic allergic reaction characterised by a variable combination of circulatory collapse, bronchospasm, laryngeal stridor, angioedema and urticaria. The risk of death is increased in patients with pre-existing asthma, particularly if this is poorly controlled, and in situations where treatment with adrenaline (epinephrine) is delayed.

### Presentation

Anaphylaxis occurs when an allergen binds to and cross-links membrane-bound IgE on mast cells in a susceptible individual, causing release of histamine, tryptase and other vasoactive mediators from mast cells. These mediators have a variety of effects, including vasodilatation, increased capillary permeability leading to hypotension, and bronchoconstriction. It can be difficult to distinguish IgE-mediated anaphylaxis clinically from non-specific degranulation of mast cells on exposure to drugs, chemicals or other triggers where IgE is not involved, previously known as anaphylactoid reactions.

### Clinical assessment

The clinical features of anaphylaxis are summarised in Figure 9.3. Several other conditions can mimic anaphylaxis and these are listed in Box 9.6.

It is important to assess the severity of the reaction, and the time between allergen exposure and onset of symptoms provides a guide. Enquiry should be made about potential triggers. If a trigger is immediately obvious, a detailed history of the previous 24 hours may be helpful. The most common triggers of anaphylaxis are foods, latex, insect venom and drugs. A history of previous local allergic responses to the offending agent is common. The route of allergen exposure may influence the principal clinical features of a reaction; for example, if an allergen is inhaled, the major symptom is frequently wheezing. Features of anaphylaxis may overlap with the direct toxic effects of drugs and venoms (Chs 7 and 8). Potentiating factors, such as exercise alcohol or fatigue, can lower the threshold for an anaphylactic event. It is important to identify precipitating

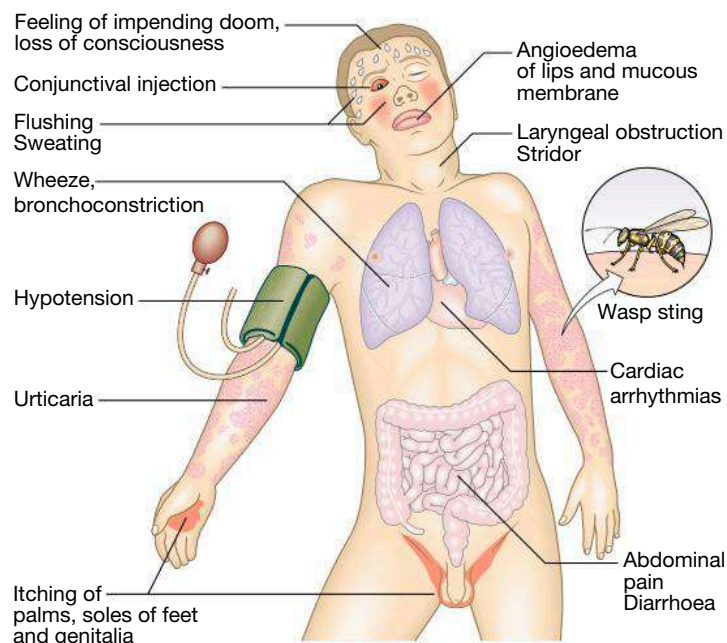

factors so that appropriate avoidance measures may be taken in the longer term.

### Investigations and management

Measurement of serum mast cell tryptase concentrations is useful to confirm the diagnosis. It is important to measure tryptase in serial tests to demonstrate the temporal relationship to the triggering event. Specific IgE tests may be useful in confirming hypersensitivity and may be preferable to skin-prick tests when investigating patients with a history of anaphylaxis. The cornerstone of management of a severe case is the early administration of adrenaline (epinephrine), which supports the cardiovascular system, reduces bronchospasm and has some disease-modifying effects. Secondary management depends upon which organs are most affected. The emergency management of anaphylaxis is summarised in Box 9.7. If present, angioedema of the orofacial area requires careful observation and timely intervention, possibly with endotracheal intubation. The investigation and management of angioedema is discussed further on page 82.

Individuals who have recovered from an anaphylactic event should be referred for specialist assessment. The aims are to identify the trigger, educate the patient regarding avoidance and management of subsequent episodes, and to establish whether specific treatment, such as immunotherapy, is indicated. If the trigger factor cannot be identified or avoided, recurrence is common. Patients who have previously

9.6 Differential diagnosis of anaphylaxis	
<b>Causes of hypotension</b>	
• Vasovagal syncope	• Cardiogenic shock
• Cardiac arrhythmia	
<b>Causes of respiratory distress</b>	
• Status asthmaticus	• Pulmonary embolus
<b>Causes of laryngeal obstruction</b>	
• C1 inhibitor deficiency	• Idiopathic angioedema
<b>Causes of generalised flushing</b>	
• Systemic mastocytosis	
• Carcinoid syndrome	

**Fig. 9.3 Clinical manifestations of anaphylaxis.** In this example, the response is to an insect sting containing venom to which the patient is allergic. This causes release of histamine and other vasoactive mediators, which lead to the characteristic features of anaphylaxis that are illustrated.

 <b>9.7 Emergency management of anaphylaxis</b>	
Treatment	Comment
Prevent further contact with allergen	Prevents ongoing mast cell activation
Ensure airway patency	Prevents hypoxia
Administer adrenaline (epinephrine) promptly: 0.3–0.5 mL 1 : 1000 solution IM in adults (0.3–0.5 mg) Repeat at 5–10 min intervals if initial response is inadequate	Intramuscular route important because of peripheral vasoconstriction Acts within minutes Increases blood pressure Reverses bronchospasm
Administer antihistamines: Chlorphenamine 10 mg IM or slow IV injection	Blocks effect of histamine on target cells
Administer glucocorticoids: Hydrocortisone 200 mg IV	Reduces cytokine release Prevents rebound symptoms in severe cases
Provide supportive treatment: Nebulised adrenaline (epinephrine) (e.g. 3 mg) Nebulised $\beta_2$ -agonists (e.g. salbutamol 5 mg) IV fluids Oxygen	Reduces airway oedema Reverses bronchospasm Restores plasma volume Reverses hypoxia
(IM = intramuscular; IV = intravenous)	

experienced an anaphylactic event should be prescribed self-injectable adrenaline (epinephrine) and they and their families or carers should be instructed in its use (Box 9.8). The use of a MedicAlert (or similar) bracelet will increase the likelihood of the injector being administered in an emergency. There is an important role for a specialist dietitian when a food trigger is the suspected allergen. Allergy in adolescence requires additional consideration and management, as set out in Box 9.9.

## Syncope/presyncope

The term 'syncope' refers to sudden loss of consciousness due to reduced cerebral perfusion. 'Presyncope' refers to lightheadedness, in which the individual thinks he or she may 'black out'. Dizziness and presyncope are particularly common in old age (Box 9.10). Symptoms are disabling, undermine confidence and independence, and can affect a person's ability to work or to drive.

There are three principal mechanisms that underlie recurrent presyncope or syncope:

- *cardiac syncope* due to mechanical cardiac dysfunction or arrhythmia
- *neurocardiogenic syncope* (also known as *vasovagal* or *reflex syncope*), in which an abnormal autonomic reflex causes bradycardia and/or hypotension
- *postural hypotension*, in which physiological peripheral vasoconstriction on standing is impaired, leading to hypotension.

There are, however, other causes of loss of consciousness, and differentiating syncope from seizure is a particular challenge. Psychogenic blackouts (also known as non-epileptic seizures or pseudoseizures) also need to be considered in the differential diagnosis.

## Presentation

The history from the patient *and* a witness is the key to establishing a diagnosis. The terms used for describing the symptoms associated with syncope vary so much among patients that they should not be taken for granted. Some patients use the term 'blackout' to describe a purely visual symptom, rather than loss of consciousness. Some may understand 'dizziness' to mean an abnormal perception of movement (vertigo),

 <b>9.8 How to prescribe self-injectable adrenaline (epinephrine)</b>	
<b>Prescription (normally initiated by an immunologist or allergist)</b>	
<ul style="list-style-type: none"> <li>• Specify the brand of autoinjector, as they have different triggering mechanisms</li> <li>• Prescribe two devices</li> </ul>	
<b>Indications</b>	
<ul style="list-style-type: none"> <li>• Anaphylaxis to allergens that are difficult to avoid:               <ul style="list-style-type: none"> <li>• Insect venom</li> <li>• Foods</li> </ul> </li> <li>• Idiopathic anaphylactic reactions</li> <li>• History of severe localised reactions with high risk of future anaphylaxis:               <ul style="list-style-type: none"> <li>• Reaction to trace allergen</li> <li>• Likely repeated exposure to allergen</li> </ul> </li> <li>• History of severe localised reactions with high risk of adverse outcome:               <ul style="list-style-type: none"> <li>• Poorly controlled asthma</li> <li>• Lack of access to emergency care</li> </ul> </li> </ul>	
<b>Patient and family education</b>	
<ul style="list-style-type: none"> <li>• Know when and how to use the device</li> <li>• Carry the device at all times</li> <li>• Seek medical assistance immediately after use</li> <li>• Wear an alert bracelet or necklace</li> <li>• Include the school in education for young patients</li> </ul>	
<b>Other considerations</b>	
<ul style="list-style-type: none"> <li>• Caution with <math>\beta</math>-adrenoceptor antagonists (<math>\beta</math>-blockers) in anaphylactic patients as they may increase the severity of an anaphylactic reaction and reduce the response to adrenaline (epinephrine)</li> </ul>	

 <b>9.9 Allergy in adolescence</b>	
<ul style="list-style-type: none"> <li>• <b>Resolution of childhood allergy:</b> most children affected by allergy to milk, egg, soybean or wheat will grow out of their food allergies by adolescence, but allergies to peanuts, tree nuts, fish and shellfish are frequently life-long.</li> <li>• <b>Risk-taking behaviour and fatal anaphylaxis:</b> serious allergy is increasingly common in adolescents and this is the highest risk group for fatal, food-induced anaphylaxis. This is associated with increased risk-taking behaviour, and food-allergic adolescents are more likely than adults to eat unsafe foods, deny reaction symptoms and delay emergency treatment.</li> <li>• <b>Emotional impact of food allergies:</b> some adolescents may neglect to carry a prescribed adrenaline (epinephrine) autoinjector because of the associated nuisance and/or stigma. Surveys of food-allergic teenagers reveal that many take risks because they feel socially isolated by their allergy.</li> </ul>	

 <b>9.10 Dizziness in old age</b>	
<ul style="list-style-type: none"> <li>• <b>Prevalence:</b> common, affecting up to 30% of people aged &gt; 65 years.</li> <li>• <b>Symptoms:</b> most frequently described as a combination of unsteadiness and lightheadedness.</li> <li>• <b>Most common causes:</b> postural hypotension and cardiovascular disease. Many patients have more than one underlying cause.</li> <li>• <b>Arrhythmia:</b> can present with lightheadedness either at rest or on activity.</li> <li>• <b>Anxiety:</b> frequently associated with dizziness but rarely the only cause.</li> <li>• <b>Falls:</b> multidisciplinary workup is required if dizziness is associated with falls.</li> </ul>	

some will consider this a feeling of faintness, and others will regard it as unsteadiness. The clinician thus needs to elucidate the exact nature of the symptoms that the patient experiences. The potential differential diagnosis of syncope and presyncope, on the basis of the symptoms described, is shown in Figure 9.4.

The history should always be supplemented by a *direct eye-witness account* if available. Careful history with corroboration will usually establish whether there has been full consciousness, altered consciousness, vertigo, transient amnesia or something else. Attention should be paid to potential triggers (e.g. medication, micturition, exertion, prolonged standing), the

**Fig. 9.4** The differential diagnosis of syncope and presyncope.

patient's appearance (e.g. colour, seizure activity), the duration of the episode, and the speed of recovery (Box 9.11). Cardiac syncope is usually sudden, but can be associated with premonitory lightheadedness, palpitation or chest discomfort. The blackout is usually brief and recovery rapid. Exercise-induced syncope can be the presenting feature of a number of serious pathologies (such as hypertrophic obstructive cardiomyopathy or exercise-induced arrhythmia) and always requires further investigation. Neurocardiogenic syncope will often be associated with a situational trigger (such as pain or emotion), and the patient may experience flushing, nausea, malaise and clamminess for several minutes afterwards. Recovery is usually quick and without subsequent delirium, provided the patient has assumed a supine position. There is often some brief stiffening and limb-twitching, which requires differentiation from seizure-like movements. It is rare for syncope to cause injury or to cause amnesia after regaining awareness. Patients with seizures do not exhibit pallor, may have abnormal movements, usually take more than 5 minutes to recover and are often

confused. Aspects of the history that can help to differentiate seizure from syncope are shown in Box 9.12.

A diagnosis of psychogenic blackout (also known as non-epileptic seizure, pseudoseizure or psychogenic seizure) may be suggested by specific emotional triggers, dramatic movements or vocalisation, or by very prolonged duration (hours). A history of rotational vertigo is suggestive of a labyrinthine or vestibular disorder (p. 1143). Postural hypotension is normally obvious from the history, with presyncope or, less commonly, syncope occurring within a few seconds of standing. The history should include enquiry about predisposing medications (diuretics, vasodilators, antidepressants) and conditions (such as diabetes mellitus and Parkinson's disease).

### **Clinical assessment**

Examination of the patient may be entirely normal, but may reveal clinical signs that favour one form of syncope. The systolic murmurs of aortic

<b>i</b> 9.11 Typical features of cardiac syncope, neurocardiogenic syncope and seizures			
	Cardiac syncope	Neurocardiogenic syncope	Seizures
<b>Premonitory symptoms</b>	Often none Lightheadedness Palpitation Chest pain Breathlessness	Nausea Lightheadedness Sweating	Delirium Hyperexcitability Olfactory hallucinations 'Aura'
<b>Unconscious period</b>	Extreme 'death-like' pallor	Pallor	Prolonged (> 1 min) unconsciousness Motor seizure activity* Tongue-biting Urinary incontinence
<b>Recovery</b>	Rapid (< 1 min) Flushing	Rapid Nausea Lightheadedness	Prolonged delirium (> 5 mins) Headache Focal neurological signs

\*N.B. Cardiac syncope can also cause convulsions by inducing cerebral anoxia.

<b>9.12 How to differentiate seizures from syncope</b>		
	Seizure	Syncope
<b>Aura</b> (e.g. olfactory)	+	–
<b>Cyanosis</b>	+	–
<b>Lateral tongue-biting</b>	+	–/+
<b>Post-ictal delirium</b>	+	–
<b>Post-ictal amnesia</b>	+	–
<b>Post-ictal headache</b>	+	–
<b>Rapid recovery</b>	–	+

stenosis or hypertrophic obstructive cardiomyopathy are important findings, particularly if paired with a history of lightheadedness or syncope on exertion. BP taken when supine and then after 1 and 3 minutes of standing may, when combined with symptoms, provide robust evidence of symptomatic postural hypotension.

Clinical suspicion of hypersensitive carotid sinus syndrome (sensitivity of carotid baroreceptors to external pressure such as a tight collar) should prompt monitoring of the ECG and BP during carotid sinus pressure, provided there is no carotid bruit or history of cerebrovascular disease. A positive cardio-inhibitory response is defined as a sinus pause of 3 seconds or more; a positive vasodepressor response is defined as a fall in systolic BP of more than 50 mmHg. Carotid sinus pressure will produce positive findings in about 10% of older adults, but fewer than 25% of these experience spontaneous syncope. Symptoms should not, therefore, be attributed to hypersensitive carotid sinus syndrome unless they are reproduced by carotid sinus pressure.

### Initial investigations

A 12-lead ECG is essential in all patients presenting with syncope or presyncope. Lightheadedness may occur with many arrhythmias, but blackouts (Stokes–Adams attacks) are usually due to profound bradycardia or malignant ventricular tachyarrhythmias. The ECG may show evidence of conducting system disease (e.g. sinus bradycardia, atrioventricular block, bundle branch block), which would predispose a patient

to bradycardia, but the key to establishing a diagnosis is to obtain an ECG recording *while symptoms are present*. Since minor rhythm disturbances are common, especially in older adults, symptoms must occur at the same time as a recorded arrhythmia before a diagnosis can be made. Ambulatory ECG recordings are helpful only if symptoms occur several times per week. Patient-activated ECG recorders are useful for examining the rhythm in patients with recurrent dizziness, but are not helpful in assessing sudden blackouts. When these investigations fail to establish a cause in patients with presyncope or syncope, an implantable ECG recorder can be sited subcutaneously over the upper left chest. This device continuously records the cardiac rhythm and will activate automatically if extreme bradycardia or tachycardia occurs. The ECG memory can also be tagged by the patient, using a hand-held activator as a form of 'symptom diary'. Stored ECGs can be accessed by the implanting centre, using a telemetry device in a clinic, or using a home monitoring system via an online link.

Head-up tilt-table testing is a provocation test used to establish the diagnosis of vasovagal syncope. It involves positioning the patient supine on a padded table that is then tilted to an angle of 60–70° for up to 45 minutes, while the ECG and BP responses are monitored. A positive test is characterised by bradycardia (cardio-inhibitory response) and/or hypotension (vasodepressor response), associated with typical symptoms.

## Headache

Headache is common and causes considerable worry amongst both patients and clinicians, but rarely represents sinister disease. The causes may be divided into primary or secondary, with primary headache syndromes being vastly more common (Box 9.13).

### Presentation

The primary purpose of the history and clinical examination in patients presenting with headache is to identify the small minority of patients with serious underlying pathology. Key features of the history include the temporal evolution of a headache; a headache that reached maximal intensity immediately or within 5 minutes of onset requires rapid assessment for possible subarachnoid haemorrhage. Other 'red flag' symptoms are shown in Box 9.14.

It is important to establish whether the headache comes and goes, with periods of no headache in between (usually migraine), or whether it is present all or almost all of the time. Associated features, such as preceding visual symptoms, nausea/vomiting or photophobia/phonophobia, may support a diagnosis of migraine but others, such as progressive focal symptoms or constitutional upset like weight loss, may suggest a more sinister cause. The headache of cerebral venous thrombosis may be 'throbbing' or 'band-like' and associated with nausea, vomiting or hemiparesis. Raised intracranial pressure (ICP) headache

<b>i</b> 9.13 Primary and secondary headache syndromes	
<b>Primary headache syndromes</b>	
<ul style="list-style-type: none"> <li>• Migraine (with or without aura)</li> <li>• Tension-type headache</li> <li>• Trigeminal autonomic cephalalgia (including cluster headache)</li> <li>• Primary stabbing/coughing/exertional/sex-related headache</li> <li>• Thunderclap headache</li> <li>• New daily persistent headache syndrome</li> </ul>	
<b>Secondary causes of headache</b>	
<ul style="list-style-type: none"> <li>• Medication overuse headache (chronic daily headache)</li> <li>• Intracranial bleeding (subdural haematoma, subarachnoid or intracerebral haemorrhage)</li> <li>• Raised intracranial pressure (brain tumour, idiopathic intracranial hypertension)</li> <li>• Infection (meningitis, encephalitis, brain abscess)</li> <li>• Inflammatory disease (temporal arteritis, other vasculitis, arthritis)</li> <li>• Referred pain from other structures (orbit, temporomandibular joint, neck)</li> </ul>	

**9.14 'Red flag' symptoms in headache**

Symptom	Possible explanation
Sudden onset (maximal immediately or within 5 min)	Subarachnoid haemorrhage Cerebral venous sinus thrombosis Pituitary apoplexy Meningitis
Focal neurological symptoms (other than for typically migrainous)	Intracranial mass lesion: Vascular Neoplastic Infection
Constitutional symptoms: Weight loss General malaise Pyrexia Meningism Rash	Meningitis Encephalitis Neoplasm (lymphoma or metastases) Inflammation (vasculitis)
Raised intracranial pressure (worse on waking/lying down, associated vomiting)	Intracranial mass lesion
New-onset aged > 60 years	Temporal arteritis

**9.15 Identification of bacterial meningitis**

In patients presenting with headache, identification of those with bacterial meningitis is a top priority to facilitate rapid antibiotic treatment. In almost all cases there will be one of the following features:

- meningism (neck stiffness, photophobia, positive Kernig's sign)
- fever > 38°C
- signs of shock (tachycardia, hypotension, elevated serum lactate)
- rash (not always petechial).

tends to be worse in the morning and when lying flat or coughing, and associated with nausea and/or vomiting.

A description of neck stiffness along with headache and photophobia should raise the suspicion of meningitis (Box 9.15), although this may present in atypical ways in immunosuppressed, alcoholic or pregnant patients. The behaviour of the patient during headache is often instructive; migraine patients typically retire to bed to sleep in a dark room, whereas cluster headache often induces agitated and restless behaviour. The pain of a subarachnoid haemorrhage frequently causes significant distress.

Headache duration is also important to elicit; headaches that have been present for months or years are almost never sinister, whereas new-onset headache, especially in older adults, is more of a concern. In a patient over 60 years with head pain localised to one or both temples, scalp tenderness or jaw claudication, temporal arteritis (Ch. 26) should be considered.

**Clinical assessment**

An assessment of conscious level (using the Glasgow Coma Scale (GCS); Fig. 9.5) should be performed early and constantly reassessed. A decreased conscious level suggests raised ICP and urgent CT scanning (with airway protection if necessary) is indicated. A full neurological examination may provide clues as to the pathology involved; for example, brainstem signs in the context of acute-onset occipital headache may indicate vertebrobasilar dissection. Neurological signs may, however, be 'falsely localising', as in large subarachnoid haemorrhage or bacterial meningitis. Care should be taken to examine for other evidence of meningitis such as a rash (not always petechial), fever or signs of shock.

Unilateral headache with agitation, ipsilateral lacrimation, facial sweating and conjunctival injection is typical of cluster headache. Conjunctival injection may also be seen in acute glaucoma, accompanied by peri- or

**Fig. 9.5** Assessment of the Glasgow Coma Scale (GCS) score in an obtunded patient. Avoid using a sternal rub, as it causes bruising.

retro-orbital pain, clouding of the cornea, decreased visual acuity and, often, systemic upset. Temporal headaches in patients over 60 should prompt examination for enlarged or tender temporal arteries and palpation of temporal pulses (often absent in temporal arteritis). Visual acuity should be assessed promptly, as visual loss is an important complication of temporal arteritis.

**Initial investigations**

If there is any alteration of conscious level, focal neurological signs, new-onset seizures or a history of head injury, then CT scanning of the head is indicated. The urgency of scanning will depend on the clinical picture and trajectory but in many circumstances will be immediately

required. Intracranial haemorrhage or a space-occupying lesion with mass effect should prompt urgent neurosurgical referral. If bacterial meningitis is suspected (see [Box 9.15](#)), cerebrospinal fluid (CSF) analysis is required to make a definite diagnosis. Antibiotics should not be delayed for lumbar puncture (LP), which needs to be preceded by CT scanning only if raised ICP is suspected. In cases of thunderclap headache (peak intensity within 5 minutes and lasting over an hour), a normal CT scan should be followed by an LP performed more than 12 hours after headache onset, to look for evidence of xanthochromia. A negative CT scan within 6 hours of headache onset has a high degree of sensitivity for detecting subarachnoid blood. In such cases, a discussion of risks and benefits with the patient may conclude that an LP is not necessary to exclude subarachnoid haemorrhage, although a CT angiogram may be considered to exclude other pathology, such as arterial dissection. Many headaches require prompt involvement of specialists. Features of acute glaucoma, for example, require immediate ophthalmological review for measurement of intraocular pressures. Suspected temporal arteritis with an erythrocyte sedimentation rate (ESR) of >50 mm/hr should prompt immediate glucocorticoid therapy and rheumatological referral (see [Ch. 26](#) for management). Features of raised ICP in the absence of a mass lesion on neuroimaging may indicate idiopathic intracranial hypertension; CSF opening pressure is likely to be informative.

### Unilateral leg swelling

Most leg swelling is caused by oedema, the accumulation of fluid within the interstitial space. There are three explanatory mechanisms for development of oedema, which are described in [Box 9.16](#). Unilateral swelling usually indicates a localised pathology in either the venous or the lymphatic system, while bilateral oedema often represents generalised fluid overload combined with the effects of gravity. However, all causes of unilateral leg swelling may present bilaterally, and generalised fluid overload may present with asymmetrical (and therefore apparently unilateral) oedema. Fluid overload may be the result of cardiac failure, pulmonary hypertension (even in the absence of right ventricular failure), renal failure, hypoalbuminaemia or drugs (calcium channel blockers, glucocorticoids, mineralocorticoids, non-steroidal anti-inflammatory drugs (NSAIDs) and others); see [Box 16.14](#) for other causes. The remainder of this section focuses on the causes of 'unilateral' oedema.

#### Presentation

Any patient who presents with unilateral leg swelling should be assessed with the possibility of deep vein thrombosis (DVT) in mind. The pain and swelling of a DVT is often fairly gradual in onset, over hours or even days. Sudden-onset pain in the posterior aspect of the leg is more consistent with gastrocnemius muscle tear (which may be traumatic or spontaneous) or a ruptured Baker's cyst. Leg swelling and pain associated with paraesthesia or paresis, or in the context of lower limb injury or reduced conscious level, should always prompt concern regarding the possibility of compartment syndrome ([Box 9.17](#)).

#### Clinical assessment

Lower limb DVT characteristically starts in the distal veins, causing an increase in temperature of the limb and dilatation of the superficial veins. Often, however, symptoms and signs are minimal.

Cellulitis is usually characterised by erythema and skin warmth localised to a well-demarcated area of the leg and may be associated with an obvious source of entry of infection (e.g. leg ulcer or insect bite). The patient may be febrile and systemically unwell. Superficial thrombophlebitis is more localised; erythema and tenderness occur along the course of a firm, palpable vein.

Examination of any patient presenting with leg swelling should include assessment for malignancy (evidence of weight loss, a palpable mass or lymphadenopathy). Malignancy is a risk factor for DVT, but pelvic or lower abdominal masses can also produce leg swelling by compressing the pelvic veins or lymphatics. Early lymphoedema is indistinguishable from other causes of oedema. More chronic lymphoedema is firm

### 9.16 Mechanisms of oedema

There are three explanatory mechanisms for the development of oedema that may occur in isolation or combination:

- increased hydrostatic pressure in the venous system due to increased intravascular volume or venous obstruction
- decreased oncotic pressure secondary to a decrease in the plasma proteins that retain fluid within the circulation
- obstruction to lymphatic drainage ('lymphoedema').

### 9.17 Identification of compartment syndrome

- Compartment syndrome classically occurs following extrinsic compression of a limb due to trauma or reduced conscious level (especially when caused by drugs or alcohol).
- It usually presents with a tense, firm and exquisitely painful limb.
- The pain is characteristically exacerbated by passive muscle stretching or squeezing the compartment.
- Altered sensation may be evident distally.
- Absent peripheral pulses are a late sign and their presence does not exclude the diagnosis.
- Clinical suspicion of compartment syndrome should prompt measurement of creatine kinase and urgent surgical review.

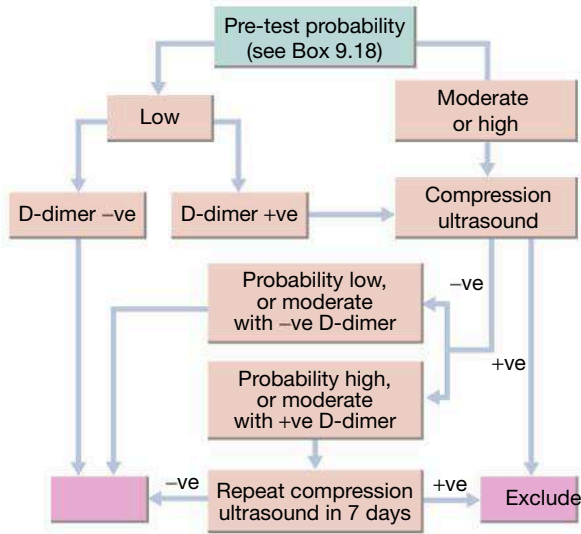

and non-pitting, often with thickening of the overlying skin, which may develop a 'cobblestone' appearance.

Chronic venous insufficiency is a cause of long-standing oedema that, particularly when combined with another cause of leg swelling, may acutely worsen. Characteristic skin changes (haemosiderin deposition, hair loss, varicose eczema, ulceration) and prominent varicosities are common, and sometimes cause diagnostic confusion with cellulitis. See [Box 9.17](#) for the examination findings associated with compartment syndrome.

#### Initial investigations

Factors predisposing to venous thromboembolism are covered in detail in [Chapter 25](#). Clinical criteria can be used to rank patients according to their likelihood of DVT, by using scoring systems that determine pre-test probability (see [Ch. 1](#)), such as the Wells score ([Box 9.18](#)). [Figure 9.6](#) gives an algorithm for investigation of suspected DVT based on initial Wells score. In patients with a low ('unlikely') pre-test probability of DVT, D-dimer levels can be measured; if these are normal, further investigation for DVT is unnecessary. Further information on the interpretation of D-dimer is given in [Box 9.19](#). In those with a moderate or high ('likely') probability of DVT or with elevated D-dimer levels, objective diagnosis of DVT should be obtained using appropriate imaging, usually a Doppler ultrasound scan. Therefore, in the same way as for pulmonary embolus, the investigative pathway for DVT differs according to the pre-test probability of DVT. For low-probability DVT, the negative predictive value of the D-dimer test (the most important parameter in this context) is over 99%; if the test is negative, the clinician can discharge the patient with confidence. In patients with a high probability of DVT, the negative predictive value of a D-dimer test falls to somewhere in the region of 97%–98%. While this may initially appear to be a high figure, to discharge 2 or 3 patients in every 100 incorrectly would generally be considered an unacceptable error rate. Hence, with the exception of pregnancy ([Box 9.20](#)), a combination of clinical probability and blood test results should be used in the diagnosis of DVT.

If cellulitis is suspected, serum inflammatory markers, skin swabs and blood cultures should be sent, ideally before antibiotics are given. Ruptured Baker's cyst and calf muscle tear can both be readily diagnosed on ultrasound. If pelvic or lower abdominal malignancy is suspected, a prostate-specific antigen (PSA) level should be measured in males and appropriate imaging with ultrasound (transabdominal or transvaginal) or CT should be undertaken.

**Fig. 9.6** Investigation of suspected deep vein thrombosis. Pre-test probability is calculated in Box 9.18. See also page 10.

9.18 Predicting the pre-test probability of deep vein thrombosis (DVT) using the Wells score*	
Clinical characteristic	Score
Previous documented DVT	1
Active cancer (patient receiving treatment for cancer within previous 6 months or currently receiving palliative treatment)	1
Paralysis, paresis or recent plaster immobilisation of lower extremities	1
Recently bedridden for $\geq 3$ days, or major surgery within previous 12 weeks	1
Localised tenderness along distribution of deep venous system	1
Entire leg swollen	1
Calf swelling at least 3 cm larger than that on asymptomatic side (measured 10 cm below tibial tuberosity)	1
Pitting oedema confined to symptomatic leg	1
Collateral superficial veins (non-varicose)	1
Alternative diagnosis at least as likely as DVT	-2
Clinical probability	Total score
DVT low probability	< 1
DVT moderate probability	1–2
DVT high probability	> 2

\*A dichotomised revised Wells score, which classifies patients as 'unlikely' or 'likely', may also be used.

## Acute abdomen

The acute abdomen accounts for approximately 50% of all urgent admissions to general surgical units, but a significant proportion of patients present via acute medicine.

### Presentation

The acute abdomen is a consequence of one or more of the following pathological processes (Box 9.21):

- **Inflammation.** Pain develops gradually, usually over several hours. It is initially rather diffuse until the parietal peritoneum is involved, when

**9.19 D-dimer**

- D-dimers are specific cross-linked fibrin degradation products which are small protein fragments present in blood after a blood clot is degraded by fibrinolysis.
- D-dimers are present in human blood when the coagulation system has been activated, usually because of the presence of thrombosis, disseminated intravascular coagulation or venom-induced consumptive coagulopathy.
- As the sensitivity of D-dimer decreases with time, it should not be used in the assessment of patients who present with symptoms for 7 days or more.
- D-dimer increases with age; for patients aged over 50 years with suspected venous thromboembolism (VTE), a cut-off equal to the patient's age in years  $\times 10 \mu\text{g/L}$  (or  $\times 0.056 \text{ nmol/L}$ ) has therefore been proposed.
- Although their safety is still being evaluated, age-adjusted D-dimers appear to decrease the false-positive rate without substantially increasing the false-negative rate

**9.20 Swollen legs in pregnancy**

Treat

- **Benign swollen legs:** common in pregnancy; this is usually benign.
- **DVT:** pregnancy is a significant risk factor; however
- **D-dimer:** should not be measured in pregnancy; it has not been validated in this group.
- **Imaging:** should be arranged on the basis of clinical suspicion alone, and the threshold for undertaking a definite diagnostic test should be low.

**9.21 Causes of acute abdominal pain**

**Inflammation**

- Appendicitis
- Diverticulitis
- Cholecystitis
- Pelvic inflammatory disease
- Pancreatitis
- Pyelonephritis
- Intra-abdominal abscess

**Perforation/rupture**

- Peptic ulcer
- Diverticular disease
- Ovarian cyst
- Aortic aneurysm

**Obstruction**

- Intestinal obstruction
- Biliary colic
- Ureteric colic

**Other (rare)**

- See Box 23.22

it becomes localised. Movement exacerbates the pain; abdominal rigidity and guarding occur.

- **Perforation.** When a viscus perforates, pain starts abruptly; it is severe and leads to generalised peritonitis.
- **Obstruction.** Pain is colicky, with spasms that cause the patient to writhe around and double up. Colicky pain that does not disappear between spasms suggests complicating inflammation.
- **Ischaemia.** Signs are variable; pain may come on acutely or more gradually and the abdomen can be soft or rigid. A raised venous lactate is usually only a late sign once hepatic lactate clearance is overwhelmed (see Fig. 9.14).

### Clinical assessment

If there are signs of peritonitis (guarding and rebound tenderness with rigidity), the patient should be resuscitated with titrated oxygen, intravenous fluids and antibiotics; urgent surgical input is required. In other circumstances, further investigations may be necessary, as detailed below (Fig. 9.7).

### Initial investigations

Patients should have a full blood count, urea and electrolytes, glucose and amylase taken to look for evidence of dehydration, leucocytosis and

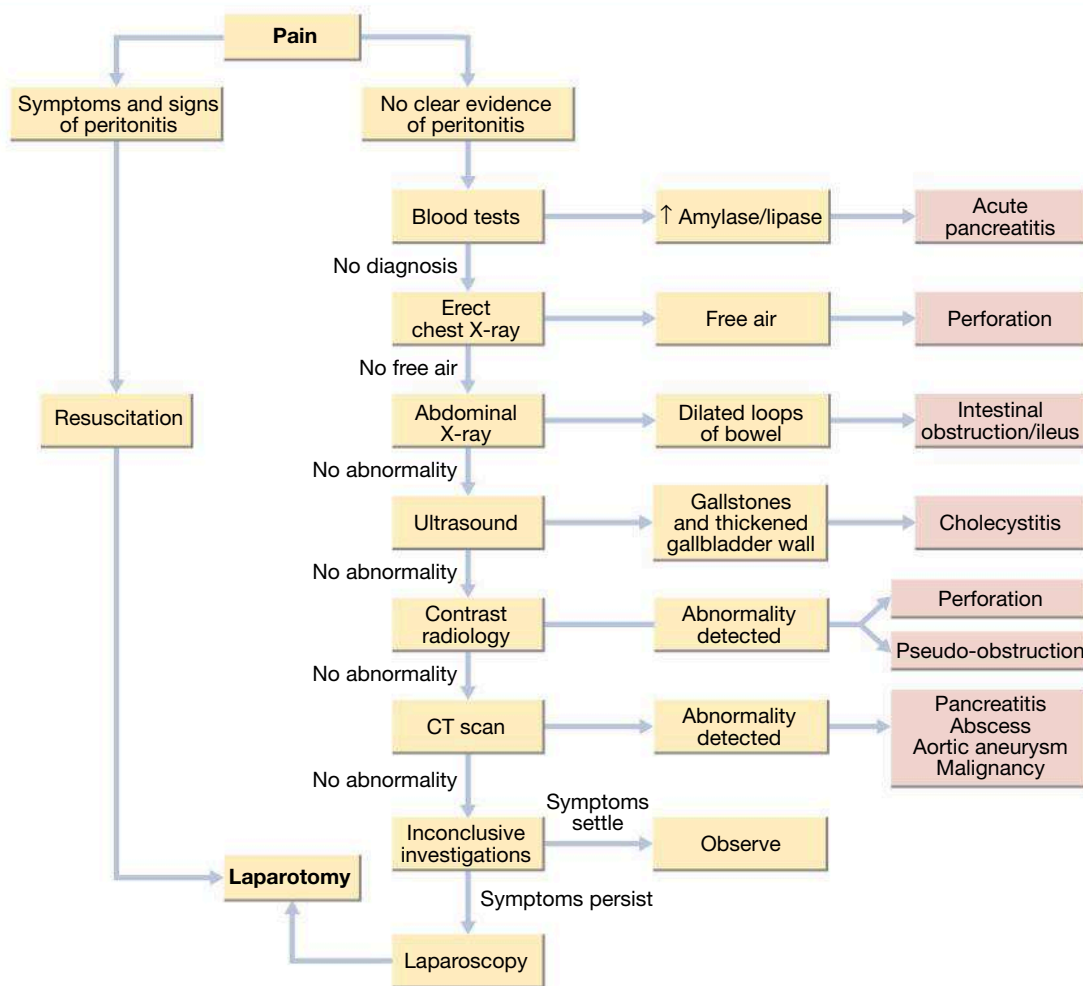

Fig. 9.7 Management of acute abdominal pain: an algorithm.

pancreatitis. Urinalysis is useful in suspected renal colic and pyelonephritis. An erect chest X-ray may show air under the diaphragm, suggestive of perforation, and a plain abdominal film may show evidence of obstruction or ileus (see Fig. 23.11). An abdominal ultrasound may help in identifying gallstones, renal stones, free fluid or an intra-abdominal abscess. Abdominal CT scanning is the most useful investigation, and is essential in differentiating pseudo-obstruction and mechanical large bowel obstruction. Concerns regarding contrast-induced nephropathy should be secondary to the imperative to reach an early diagnosis. CT may also be useful to seek evidence of pancreatitis, retroperitoneal collections or masses, including aortic aneurysm.

Diagnostic laparotomy should be considered when the diagnosis has not been revealed by other investigations. All patients must be carefully and regularly reassessed (every 2–4 hours) so that any change in condition that might alter both the suspected diagnosis and clinical decision can be observed and acted on early.

### Management

The general approach is to close perforations, treat inflammatory conditions with antibiotics or resection, and relieve obstructions. Aspiration of gastric contents is a major risk in all acute abdominal conditions, especially intestinal obstruction. This occurs once the laryngeal reflexes are overwhelmed by the volume of regurgitated material, and is particularly common in frailer individuals or where there is a coexisting reduction in conscious level. The placement of a large-bore nasogastric tube should therefore be considered whenever bowel obstruction is suspected. The speed of intervention and the necessity for surgery depend upon various factors, of which the presence of peritonitis is the most pertinent.

A treatment summary of some of the more common surgical conditions follows:

- *Acute appendicitis*: This should be treated by early surgery, since there is a risk of perforation and recurrent attacks with non-operative treatment. The appendix can be removed through a conventional right iliac fossa skin crease incision or by laparoscopic techniques.
- *Acute cholecystitis*: This can be successfully treated non-operatively but the high risk of recurrent attacks and the low morbidity of surgery have made early laparoscopic cholecystectomy the treatment of choice unless there are other considerations (such as pregnancy).
- *Acute diverticulitis*: Conservative therapy is standard, but if perforation has occurred, resection is advisable. Depending on peritoneal contamination and the degree of shock (risk of anastomotic leak correlates with severity of shock), primary anastomosis is preferable to a Hartmann's procedure (oversew of rectal stump and end-colostomy).
- *Small bowel obstruction*: If the cause is obvious and surgery inevitable (such as with a strangulated hernia), an early operation is appropriate. If the suspected cause is adhesions from previous surgery, only those patients who do not resolve within the first 48 hours or who develop signs of strangulation (colicky pain becoming constant, peritonitis, tachycardia, fever, leucocytosis) should have surgery.
- *Large bowel obstruction*: Pseudo-obstruction should be treated non-operatively. Some patients benefit from colonoscopic decompression, but mechanical obstruction merits resection, usually with a primary anastomosis. Differentiation between the two can be made by water-soluble contrast enema.

- *Mesenteric ischaemia*: This can be due to an arterial or venous thrombosis, or a structural abnormality of the gut such as a volvulus. Early surgery can be successful in revascularisation of the gut or removing ischaemic tissue, although acute mesenteric arterial thrombosis has a poor prognosis, especially when the diagnosis is delayed.
- *Acute pancreatitis*: CT scanning can be useful to rule out other pathologies that may be amenable to operative management (e.g. retroperitoneal perforation), but is not essential in the early management of the disease. Management is usually conservative, and the majority of patients will improve. A minority will develop pancreatic necrosis that will require prolonged supportive care and organ support. Antibiotics are not usually indicated in the early phase of the disease.
- *Perforated peptic ulcer*: Surgical closure of the perforation is standard practice, but some patients without generalised peritonitis can be treated non-operatively once a water-soluble contrast meal has confirmed spontaneous sealing of the perforation. Adequate and aggressive resuscitation with intravenous fluids, antibiotics and analgesia is mandatory before surgery.

For a more detailed discussion of acute abdominal pain, the reader is referred to the companion volume of this text, *Principles and Practice of Surgery*.

## Identification and assessment of deterioration

### Early warning scores and the role of the medical emergency team

There are many systems that have been developed with the aim of rapidly identifying and managing physiological deterioration. These are referred to as 'rapid response systems'. One popular example of a rapid response system is a medical emergency team (MET). A MET system operates on the basis that when a patient meets certain physiological criteria, the team is alerted. The team is expected to make a rapid assessment and institute immediate management. This may include escalation to critical care or, following liaison with the parent clinical team, ongoing ward-based care.

The trigger for a 'MET' call may be a single parameter – such as a low BP or tachycardia – or may consist of a composite early warning score. Early warning score systems function by the observer allocating a value between 0 and 3 for abnormalities in respiratory rate,  $SpO_2$ , temperature, BP, heart rate and neurological response (Fig. 9.8). The values are summed and the composite score gives an indication of the severity of physiological derangement. Early warning systems can be automated into an electronic format that calculates the score and even alerts the responsible clinician(s) by email or text message.

There are advantages and disadvantages to having a separate MET system, compared with allowing the responsible clinical team to manage deterioration, and to having a composite score or a single parameter detection system. These are outlined in Box 9.22.

### Immediate assessment of the deteriorating patient

An approach to assessment of the deteriorating patient can be summarised by the mnemonic 'C-A-B-C-D-E'.

#### C – Control of obvious problem

For example, if the patient has ventricular tachycardia on the monitor or significant blood loss is apparent, immediate action is required.

#### A and B – Airway and breathing

If the patient is talking in full sentences, then the airway is clear and breathing is adequate. A rapid history should be obtained while the

initial assessment is undertaken. Breathing should be assessed with a focused respiratory examination. Oxygen saturations and ABGs should be checked early (p. 194).

#### C – Circulation

A focused cardiovascular examination should include heart rate and rhythm, blood pressure, jugular venous pressure, evidence of bleeding, signs of shock and abnormal heart sounds. The carotid pulse should be palpated in the collapsed or unconscious patient, but peripheral pulses also should be checked in conscious patients. The radial, brachial, foot and femoral pulses may disappear as shock progresses, and this indicates the severity of circulatory compromise.

#### D – Disability

Conscious level should be assessed using the GCS (see Fig. 9.5 and Box 9.29). A brief neurological examination looking for focal signs should be performed. Capillary blood glucose should always be measured to exclude hypoglycaemia or severe hyperglycaemia.

#### E – Exposure and evidence

'Exposure' indicates the need for targeted clinical examination of the remaining body systems, particularly the abdomen and lower limbs. 'Evidence' may be gathered via a collateral history from other health-care professionals or family members, recent investigations, prescriptions or monitoring charts.

### Selecting the appropriate location for ongoing management and anticipatory care planning

Two groups of patients frequently gain benefit from admission to critical care: those with organ dysfunction severe enough to require organ support and those in whom the disease process is clearly setting them on a downward trajectory and in whom early, aggressive management may alter the outcome. Whether an individual patient should be admitted to the intensive care or high-dependency unit (ICU/HDU) will depend on local arrangements. A useful tool to assist with the decision regarding location is the 'level of care' required (Box 9.23). Many intensive care units are a mix of level 2 and level 3 beds, which streamlines the admission process. When a patient requires admission with a suspected transmissible disease that poses a risk to other patients and staff, the patient should be admitted to an isolated room located within an appropriate area of the hospital that can provide an appropriate level of care.

Anticipatory care planning (ACP) refers to the process of decision-making relating to treatments or support that would be appropriate if a patient's condition was to deteriorate. Admission can be a valuable opportunity for discussion with the patient and family members/carers about the appropriate 'ceiling of care'; for example, would resuscitation in the event of a cardiac arrest and/or admission to a critical care area be appropriate. Such discussions may result in the placement of a 'do not resuscitate order' and a decision that 'ward-level' care may be the 'ceiling' for that individual. It is important that discussions and decisions are clearly documented in the patient record. Further details of ACP decision-making are found on page 206.

## Common presentations of deterioration

As patients become critically unwell, they usually manifest physiological derangement. The principle underpinning critical care is the simultaneous assessment of illness severity and the stabilisation of life-threatening physiological abnormalities. The goal is to prevent deterioration and

Fig. 9.8, cont'd

i 9.22 Advantages and disadvantages of different rapid response systems		
System	Advantages	Disadvantages
Single parameter trigger	High sensitivity. Will probably pick up subclinical deterioration and allow optimisation	Low specificity. Much time will be spent with patients who are not deteriorating
Composite early warning scoring system, e.g. NEWS2	Combines good sensitivity with improved specificity	May miss single parameter deterioration that is still significant, e.g. a drop of 2 GCS points may not trigger an alert
MET system	Brings expertise in deteriorating patients immediately to the bedside	Expensive to have well-trained individuals who are free from other clinical duties. May de-skill the ward-based teams in acute care. May not have expertise in highly specific areas of medicine
Clinical team review	Patient is seen by clinicians familiar with the patient and condition	Clinical team may be busy with other urgent duties. There may not be expertise in acute care within the ward-based team

(GCS = Glasgow Coma Scale; MET = Medical Emergency Team; NEWS2 = National Early Warning Score 2)

effect improvements, as the diagnosis is established and treatment of the underlying disease process is initiated.

It can be useful to consider the physiological changes as a starting point to help delineate urgent investigations and supportive treatment, which should proceed alongside the search for a definitive diagnosis.

## Tachypnoea

### Pathophysiology

A raised respiratory rate (tachypnoea) is the earliest and most sensitive sign of clinical deterioration. Tachypnoea may be primary (i.e. a problem within the respiratory system) or secondary to pathology elsewhere in the body. Cardiopulmonary causes of tachypnoea have been covered on page 179. Secondary tachypnoea is usually due to a metabolic acidosis, most commonly observed in the context of sepsis, haemorrhage, ketoacidosis or visceral ischaemia. More detailed information on metabolic acidosis can be found on page 630.

### Assessment and management

A simple assessment of a patient's clinical status and basic physiology will usually indicate whether urgent intervention is required. In the examination, attention should be paid to the adequacy of chest expansion, air entry and the presence of added sounds such as wheeze.

Analysis of an arterial blood sample is especially helpful in narrowing the differential diagnosis and confirming clinical suspicion of severity. The 'base excess' provides rapid quantification of the component of disease that is metabolic in origin. A base excess lower than  $-2$  mEq/L (or, put another way, a 'base deficit' of more than 2 mEq/L) is likely to represent a metabolic acidosis. A simple rule of thumb is that a lactate of more than 4 mmol/L (36 mg/dL) or a base deficit of more than 10 mEq/L should cause concern and trigger escalation to a higher level of care. In addition to clinical examination, chest radiography and bedside ultrasound can help to distinguish the cause of poor air entry; consolidation and effusion can be readily identified and a significant pneumothorax can be excluded (as shown in Fig. 9.9).

### 9.23 Levels of care and the corresponding admission criteria for intensive care unit (ICU) and high-dependency unit (HDU)

Level of care	Criteria	Appropriate location
3	Patients requiring/likely to require endotracheal intubation and invasive mechanical ventilatory support Patients requiring support of two or more organ systems (e.g. inotropes and haemofiltration) Patients with chronic impairment of one or more organ systems (e.g. COPD or severe ischaemic heart disease) who require support for acute reversible failure of another organ	ICU
2	Patients requiring detailed observation or monitoring that cannot be provided at ward level: Direct arterial BP monitoring CVP monitoring Fluid balance Neurological observations, regular GCS recording Patients requiring support for a single failing organ system, excluding invasive ventilatory support (IPPV): Non-invasive respiratory support (p. 207) Moderate inotropic or vasopressor support Renal replacement therapy in an otherwise stable patient Step-down from intensive care requiring additional monitoring or single organ support	HDU
1	Patients in whom frequent but intermittent observations and medical review are sufficient	General ward setting

(BP = blood pressure; COPD = chronic obstructive pulmonary disease; CVP = central venous pressure; GCS = Glasgow Coma Scale; IPPV = intermittent positive pressure ventilation)

**Fig. 9.9** Using ultrasound to rule out an anterior pneumothorax. **A** Probe position and orientation. **B** and **C** Two-dimensional (2D) ultrasound images. **D** and **E** M-mode ultrasound images. Key: (1) Intercostal muscle. (2) Rib. (3) Normal bright pleural line – ‘shimmering appearance’ of sliding pleura. (4) Lung. (5) Absent ‘shimmering’ in pneumothorax and lung not visible. (6) Normal – ‘sea shore’ sign excludes pneumothorax at that location. The ‘sea shore’ is represented by the bright granular line with lung (sea) deeper to the bright line. (7) Absent granular pleural line and a repeating linear pattern or ‘barcode’ sign suggest the presence of pneumothorax.

## Hypoxaemia

### Pathophysiology

Low arterial partial pressure of oxygen ( $PaO_2$ ) is termed hypoxaemia. It is a common presenting feature of deterioration. Hypoxia is defined as an inadequate amount of oxygen in tissues (or the inability of cells to use the available oxygen for cellular respiration). Hypoxia may be due to hypoxaemia, or may be secondary to impaired cardiac output, the presence of inadequate or dysfunctional haemoglobin, or intracellular dysfunction (such as in cyanide poisoning, where oxygen utilisation at the cellular level is impaired).

Over 97% of oxygen carried in the blood is bound to haemoglobin. The haemoglobin–oxygen dissociation curve delineates the relationship between the percentage saturation of haemoglobin with oxygen ( $SO_2$ ) and the partial pressure ( $PO_2$ ) of oxygen in the blood. A shift in the curve will influence the uptake and release of oxygen by the haemoglobin molecule. As capillary  $PCO_2$  rises, the curve moves to the right, increasing the offloading of oxygen in the tissues (the Bohr effect). This increases capillary  $PO_2$  and hence cellular oxygen supply. Shifts of the oxyhaemoglobin dissociation curve can have significant implications in certain disease processes (Fig. 9.10).

Due to the shape of the curve, a small drop in arterial  $PO_2$  ( $PaO_2$ ) below 8 kPa (60 mmHg) will cause a marked fall in  $SaO_2$ .

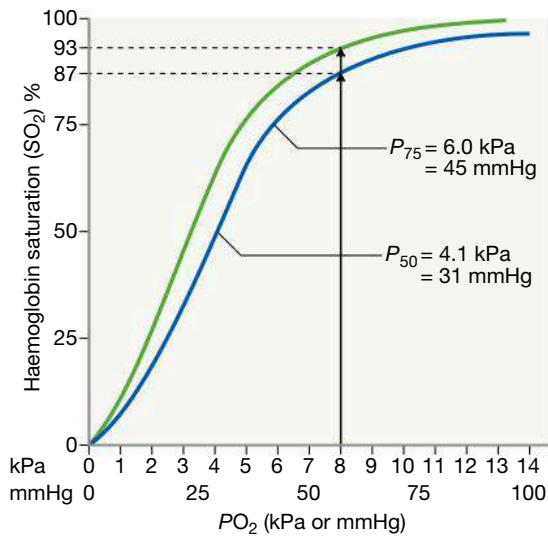

Relative hypoxaemia refers to the comparison between the observed  $PaO_2$  and that which might be expected for a given fraction of inspired oxygen ( $FIO_2$ ). With the patient breathing air,  $PaO_2$  of 12–14 kPa (90–105 mmHg) would be expected; with the patient breathing 100% oxygen, a  $PaO_2$  of > 60 kPa (450 mmHg) would be normal.

### Assessment and management

Oxygen therapy should be titrated to avoid hyperoxia (too high a  $PaO_2$ ; Box 9.24). Hyperoxia is theoretically harmful via a number of mechanisms. This has a clinically significant effect in patients with acute stroke, those with MI and those who chronically retain  $CO_2$ . Adverse effects of hyperoxia include:

- free radical-induced tissue damage
- less efficient buffering of carbon dioxide by oxyhaemoglobin (compared to deoxyhaemoglobin)
- less efficient ventilation–perfusion matching in lung units (due to loss of hypoxic vasoconstriction of under-ventilated lung units)
- decreased hypoxic respiratory drive in individuals with chronic hypercapnia.

When attempting to determine the cause of hypoxaemia, it is useful to consider whether the primary physiological mechanism is a type of

**Fig. 9.10** The haemoglobin–oxygen dissociation curve and the effect of  $\text{CO}_2$  on oxygen saturations. In pulmonary embolism, compensatory hyperventilation often occurs.  $\text{PaCO}_2$  decreases, shifting the oxyhaemoglobin saturation curve to the left (green line). Therefore, despite a low  $\text{PaO}_2$  (8 kPa/60 mmHg), the oxygen saturation reading is 93%.

#### 9.24 Prescribing oxygen in critical illness

- Oxygen should be prescribed to achieve a target saturation of 94%–98% for most critically unwell patients.
- 88%–92% is a more appropriate target range for those at risk of hypercapnic respiratory failure.
- In patients with acute myocardial infarction or stroke, do not start oxygen unless  $\text{SpO}_2$  is below 92%, as hyperoxia may be harmful.

shunt, or one of the many causes of ventilation–perfusion mismatch, such as alveolar or central hypoventilation (Fig. 9.11). A classification of common causes of hypoxaemia in hospitalised patients is shown in Box 9.25. In reality, the observed physiological abnormality may represent a combination of inter-related processes, such as severe pulmonary oedema leading to exhaustion, which in turn causes hypoventilation.

Evaluation of risk factors, history and examination will help to differentiate the likely aetiology and guide specific management. Further management of respiratory failure is discussed on page 207.

## Tachycardia

### Pathophysiology

A heart rate of  $>110$  beats/min in an adult should always be considered abnormal and not attributed to anxiety until other causes have been excluded. Intrinsic cardiac causes (atrial fibrillation (AF), atrial flutter, supraventricular tachycardia and ventricular dysrhythmias) are less common in the general inpatient population than secondary causes of tachycardia.

A cardiac monitor or 12-lead ECG early in the examination will help both determine severity (heart rate  $>160$  beats/min should prompt urgent escalation to a higher level of care) and narrow the differential diagnosis. AF with a rapid ventricular response should usually be regarded as secondary to another insult (most commonly, infection) until other diagnoses have been excluded. Hypovolaemia should not be missed. Concealed bleeding (e.g. into the pleura, gastrointestinal tract or retroperitoneum) may not be apparent initially and assessment of haemoglobin in an acute haemorrhage, when  $<30\text{ mL/kg}$  of fluid has been administered, can be misleadingly high. Sepsis and other hyper-metabolic

conditions may present with a tachycardia that is accompanied by tachypnoea, peripheral vasodilatation and a raised temperature. Other organ dysfunction should be noted from a brief general examination and salient points from the history.

### Assessment and management

The management of a tachycardic patient should focus on treating the cause. Treating the rate alone with beta-blockade in an unwell or deteriorating patient should be done only under specialist guidance, in controlled conditions and when a clear evaluation of the risk–benefit ratio has been undertaken.

The recognition and management of primary cardiac dysrhythmias are discussed on page 408. The most appropriate method of rate control in AF depends primarily on the degree of haemodynamic compromise. An intravenous loading dose of amiodarone is well tolerated and efficacious in the majority of critically ill patients with AF and a very rapid ventricular rate. There are thromboembolic concerns regarding chemical cardioversion of AF of unknown duration. However, in deteriorating patients, the low incidence of embolic events makes this concern of secondary importance to achieving haemodynamic stability.

Digoxin continues to have a role in the treatment of AF in critically unwell but haemodynamically stable patients, when its inotropic properties can be helpful. Electrical cardioversion is reserved for dysrhythmias with extremely high heart rates, following failure of pharmacological management, and/or for those of ventricular origin. It is rarely successful in dysrhythmias secondary to systemic illness.

## Hypotension

### Pathophysiology

Low BP (hypotension) should always be defined in relation to a patient's usual BP. The calculation of mean arterial pressure (MAP) is shown in Box 9.26; it unifies the systolic and diastolic BPs into a single reference value. A MAP of  $>65\text{ mmHg}$  will maintain renal perfusion in the majority of patients, although a MAP of up to  $80\text{ mmHg}$  may be required in patients with chronic hypertension.

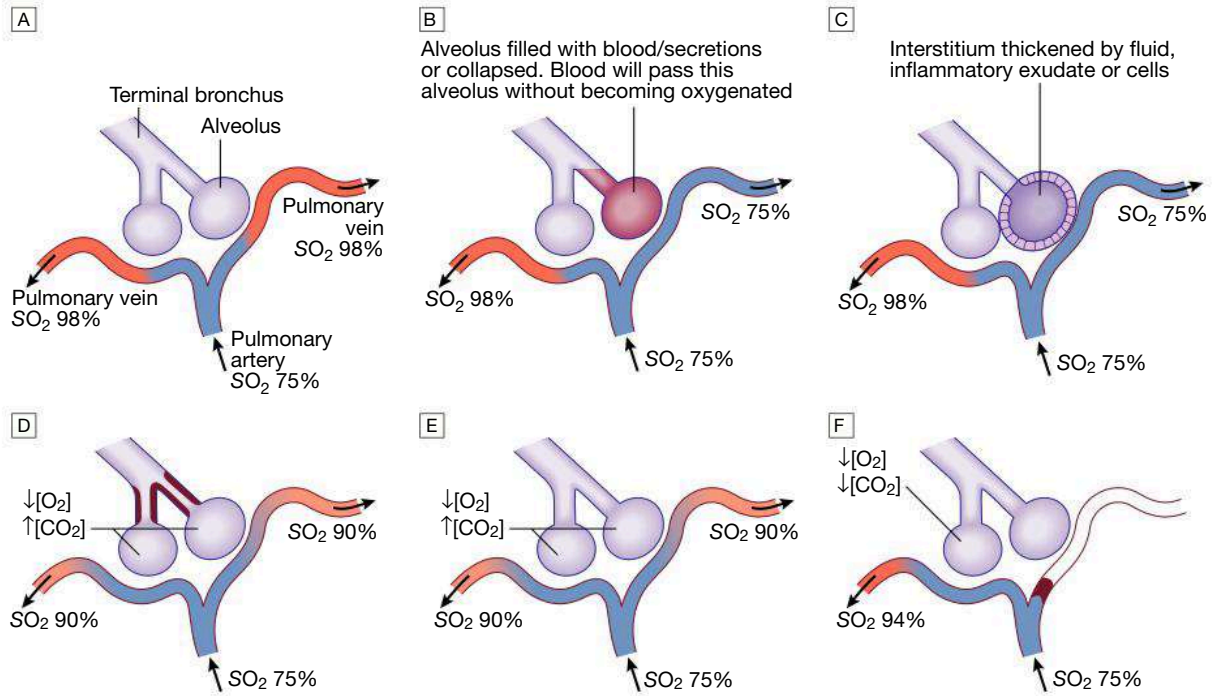

### Assessment and management

The first stage of assessment is to decide if the hypotension is physiological or pathological. The MAP is useful as, despite low systolic pressures, it is rare to see a physiological MAP of  $<65\text{ mmHg}$ . Urine output is particularly useful in the determination of the desirable MAP for an individual patient; oliguria suggests that measures to increase the MAP should be sought (p. 210). If the hypotension is pathological, an assessment of severity should look at whether it is causing physiological harm to the patient (i.e. the patient is shocked).

### Shock

Shock means 'circulatory failure'. It can be defined as a level of oxygen delivery (DO) that fails to meet the metabolic requirements of the tissues (Box 9.27). Hypotension is a common presentation of shock but the terms are not synonymous. Patients can be hypotensive but not shocked, and oxygen delivery can be critically low in the context of a 'normal' BP. Along with the signs of low cardiac output (Box 9.28), objective markers of inadequate tissue oxygen delivery, such as increasing base deficit, elevated blood lactate and reduced urine output, can aid early identification. If shock is suspected, resuscitation should be commenced (p. 210).

Hypotensive patients who do not have any evidence of shock are still at significant risk of organ dysfunction. Hypotension should serve as a 'red flag' that there may be serious underlying pathology. Organ failure occurs despite normal or elevated oxygen delivery, so a full assessment of the patient is indicated. A review of the drug chart is essential, as many inpatients will be on antihypertensive medications that are contributing to hypotension. Non-cardiac medications may also have a negative influence on BP; for example, some drugs used for urine outflow tract obstruction, such as tamsulosin, have an  $\alpha$ -adrenoceptor-blocking effect.

**Fig. 9.11** Theoretical mechanisms of hypoxaemia. **A** Normal physiology. **B** Shunt caused by alveolar filling, e.g. in pneumonia or alveolar haemorrhage. The mixture of oxygenated and deoxygenated blood causes arterial desaturation. **C** Shunt caused by interstitial pathology, e.g. pulmonary oedema or fibrosis. Interstitial thickening causes inadequate transfer of oxygen from the alveolus to the blood, leading to shunting and arterial desaturation. Because minute volume is usually maintained, this causes type I respiratory failure. **D** Ventilation–perfusion (V/Q) mismatch caused by alveolar hypoventilation, e.g. in chronic obstructive pulmonary disease (COPD)/asthma. Alveoli are under-ventilated relative to perfusion. Alveolar  $PO_2$  falls and  $PCO_2$  rises, causing type II respiratory failure. **E** (V/Q) mismatch caused by central hypoventilation, e.g. in neuromuscular disease or narcotic use. The alveoli are relatively over-perfused, causing type II respiratory failure. **F** (V/Q) mismatch caused by a perfusion defect, e.g. a small pulmonary embolism. Pulmonary blood flow is diverted to other alveoli, causing them to be relatively over-perfused and thus reducing alveolar  $PO_2$ . Minute volume is increased, so  $PCO_2$  is not elevated.

**i** **9.25 Common causes of hypoxaemia in hospitalised patients**

**Hypoxaemia due to shunt**

- Lung collapse
- Consolidation/alveolar haemorrhage
- Interstitial oedema or interstitial infiltration (e.g. fibrosis)
- Silent aspiration of gastric contents

**Hypoxaemia due to ventilation–perfusion mismatch**

- Pulmonary embolism
- Acute exacerbation of asthma
- COPD (with high minute volume)

**Hypoxaemia from hypoventilation**

- Effects of opiates
- Severe COPD (with low minute volume)
- Neuromuscular disease/general weakness from other illness

(COPD = chronic obstructive pulmonary disease)

**i** **9.26 Calculation of mean arterial pressure (MAP)**

$$MAP = \text{Diastolic blood pressure} + \frac{(\text{systolic} - \text{diastolic})}{3}$$

At normal heart rates, the heart, on average, spends two-thirds of the cycle in diastole. The MAP reflects this by weighting the value towards the diastolic blood pressure.

**i** **9.27 Oxygen content and delivery**

- Oxygen content of blood = Haemoglobin concentration\* × oxygen saturation × constant
- Cardiac output = Heart rate × stroke volume
- Stroke volume is dependent on cardiac filling (preload) and contractility.
- In shock, the most productive measures to improve oxygen delivery are optimising the haemoglobin level and the cardiac output.

\*Oxygen is almost exclusively bound to haemoglobin; only tiny amounts are dissolved in blood at atmospheric pressure.

**i** **9.28 Hypotension in relation to cardiac output: clinical signs and possible causes**

	High cardiac output	Low cardiac output
<b>Signs</b>	Warm hands Pulsatile head movement High-volume/strong pulse Low venous pressure	Cold/clammy peripheries Peripheral cyanosis Raised venous pressure (except in haemorrhage)
<b>Causes</b>	Sepsis Allergy Drug overdose (e.g. antihypertensive) Acidosis (e.g. diabetic ketoacidosis) Thyrotoxicosis Beri-beri	Bleeding Aortic stenosis and failed compensation Dysrhythmia Obstructive (pulmonary embolism/tamponade/dynamic hyperinflation as in severe asthma) Chronic heart failure

## Hypertension

### Pathophysiology

High BP (hypertension) is common and is usually benign in a critical care context. However, it can be the presenting feature of a number of serious disease processes. Furthermore, acute hypertension can result in an acute rise in vascular tone that increases left ventricular end-systolic pressure (afterload). The left ventricle may be unable to eject blood against the increased aortic pressure, and acute pulmonary oedema can result (referred to as 'flash' pulmonary oedema.)

### Assessment and management

Before treating an acute rise in BP, it is worth considering a few important diagnoses that may impact on the immediate management:

- **Intracranial event.** Ischaemia of the brainstem (commonly via a pressure effect) will cause acute increases in BP. A neurological examination and CT scan of the head should be considered.
- **Fluid overload.** Once the capacity of the venous blood reservoir becomes saturated, increases in fluid volume will lead to increases in BP. This can occur in younger patients without the onset of peripheral oedema and originate from myocardial dysfunction or impaired renal clearance.
- **Underlying medical problems.** A brief search for a history of renal disease, spinal injury and less common metabolic causes such as pheochromocytoma can be worthwhile. In women of child-bearing age, pregnancy-induced hypertension and pre-eclampsia must always be considered.
- **Primary cardiac problems.** Myocardial ischaemia, acute heart failure and aortic dissection can all present with hypertension.
- **Drug-related problems.** Most commonly, these involve a missed antihypertensive medication, but sympathomimetic drugs such as cocaine and amphetamines can be implicated.

The management of hypertension is discussed further on page 447.

## Decreased conscious level

### Assessment

A reduction in conscious level should prompt an urgent assessment of the patient, a search for the likely cause and an evaluation of the risk of airway loss. The GCS was developed to risk-stratify head injury, but it has become the most widely recognised assessment tool for conscious level (see [Box 9.29](#) for a breakdown of GCS assessment, [Box 9.30](#) for how to communicate the findings and [Fig. 9.5](#) for how to assess GCS). While disorders that affect language or limb function (e.g. left hemisphere stroke, locked-in syndrome) may reduce its usefulness, evaluation of the GCS usually provides helpful prognostic information, and serial recordings can plot improvement or deterioration. It is not possible to define a total score below which a patient is unlikely to be able to protect the airway (from aspiration or obstruction), but a motor score of less than 5 would suggest significant risk.

Coma is defined as a persisting state of deep unconsciousness. In practice, this means a sustained GCS of 8 or less. There are many causes of coma ([Box 9.31](#)), including neurological (structural or non-structural brain disease) and non-neurological (e.g. type II respiratory failure) ones. The mode of onset of coma and any precipitating event is crucial to establishing the cause, and should be obtained from witnesses. Failure to obtain an adequate history for patients in coma is a common cause of diagnostic delay.

Once the patient is stable from a cardiorespiratory perspective, examination should include accurate assessment of conscious level and a thorough general medical examination, looking for clues such as needle tracks indicating drug abuse, rashes, fever and focal signs of infection, including neck stiffness or evidence of head injury. Focal neurological

## i

### 9.29 Glasgow Coma Scale (GCS)\*

#### Eye opening (E)

• Spontaneous	4
• To speech	3
• To pain	2
• Nil	1

#### Best motor response (M)

• Obeys commands	6
• Localises to painful stimulus	5
• Flexion to painful stimulus or withdraws hand from pain	4
• Abnormal flexion (internal rotation of shoulder, flexion of wrist)	3
• Extensor response (external rotation of shoulder, extension of wrist)	2
• Nil	1

#### Verbal response (V)

• Orientated	5
• Confused conversation	4
• Inappropriate words	3
• Incomprehensible sounds	2
• Nil	1

#### Coma score = E + M + V

#### Always present GCS as breakdown, not a sum score (unless 3 or 15)

• Minimum sum	3
• Maximum sum	15

\*Record the best score observed. When the patient is intubated, there can be no verbal response. The suffix 'T' should replace the verbal component of the score, and the remainder of the score is therefore a maximum of 10.

## Yp

### 9.30 How to communicate conscious level to other health-care professionals

- It is best to state the physical response along with the numerical score.
- For example, 'a patient who doesn't open his eyes, withdraws to pain and makes groaning noises, having a GCS of E1, M4, V2, making a total of 7' is preferable to 'a male with a GCS of 7'.

## i

### 9.31 Causes of coma

#### Metabolic disturbance

• Drug overdose	• Inborn errors of metabolism causing hyperammonaemia
• Diabetes mellitus	• Hyperammonaemia on refeeding following profound anorexia
Hypoglycaemia	• Respiratory failure
Ketoacidosis	• Hypothermia
Hyperosmolar coma	• Hypothyroidism
• Hyponatraemia	
• Uraemia	
• Hepatic failure (hyperammonaemia)	

#### Trauma

• Cerebral contusion	• Subdural haematoma
• Extradural haematoma	• Diffuse axonal injury

#### Vascular disease

• Subarachnoid haemorrhage	• Intracerebral haemorrhage
• Brainstem infarction/haemorrhage	• Cerebral venous sinus thrombosis

#### Infections

• Meningitis	• Cerebral abscess
• Encephalitis	• Systemic sepsis

#### Others

• Epilepsy	• Functional ('pseudo-coma')
• Brain tumour	

**Fig. 9.12** Hyperacute changes in conscious state are commonly of vascular origin. CT of the brain is unlikely to identify many vascular causes but a CT angiogram of the circle of Willis is a high-yield investigation in this context. **A** Non-contrast CT of the head showing hyperdense thrombus in the basilar artery (arrow). This is a specific, but not sensitive, sign. **B** CT angiogram of the circle of Willis demonstrating thrombosis in the basilar artery (arrow). This has better sensitivity for acute vascular occlusion.

signs may suggest a structural explanation (stroke or tumour) or may be falsely localising (for example, 6th nerve palsy can occur as a consequence of raised intracerebral pressure). It is vital to exclude non-neurological causes of coma. Sodium and glucose should be measured urgently as part of the initial assessment, as acute hyponatraemia (Ch. 19) and hypoglycaemia (see Box 21.17) are easily corrected and can cause irreversible brain injury if missed.

Further investigations should be guided by the clinical presentation and examination findings; a sudden onset suggests a vascular cause. An early CT scan of the brain may demonstrate any gross pathology but if a brainstem stroke is suspected (Fig. 9.12), a CT angiogram of the circle of Willis will provide more useful information, as a non-contrast CT is frequently negative in this context. If there are features suggestive of cerebral venous thrombosis, such as thrombophilia or sinus infection, a CT venogram should be performed. Meningitis or encephalitis may be suggested by the history, signs of infection or subtle radiological findings. If these diagnoses are considered, it is best to commence treatment with broad-spectrum antibiotics and antivirals while awaiting more definitive diagnostic information.

Other drug, metabolic and hepatic causes of reduced conscious level are dealt with in the relevant chapters. An ammonia level (sent on ice) can narrow the differential diagnosis to a metabolic or hepatic cause if there is diagnostic doubt; levels  $> 140 \mu\text{g/dL}$  ( $100 \mu\text{mol/L}$ ) are significantly abnormal. Psychiatric conditions such as catatonic depression or neurological conditions such as the autoimmune encephalitides can cause a reduced level of consciousness, but they are diagnoses of exclusion and will require specialist input.

### Management

Moving an unconscious patient into the recovery position is best for airway protection while preparations are made for escalation to a higher level of care. The decision regarding intubation for airway protection is always difficult. Length of stay in intensive care is significantly reduced

if there is no secondary organ dysfunction. Therefore, early intubation and the prevention of lung injury constitute the safer option if there is any doubt about a patient's ability to protect the airway from obstruction or aspiration.

## Decreased urine output/deteriorating renal function

### Assessment

A urine output of  $0.5 \text{ mL/kg/hr}$  is a commonly quoted, though arbitrary target. Although some patients can produce urine volumes below this level with no change in their renal biochemistry, such low volumes should alert the clinician to the possibility of suboptimal renal perfusion.

Oliguria in association with hypotension or an increase in serum creatinine level (even if small) should prompt examination for the underlying cause. Pre-renal causes predominate in the general inpatient population, so optimising the MAP by administration of intravenous fluids (and possibly vasopressors) is the first priority. In the majority of inpatients there is no role for high volumes (i.e.  $> 30 \text{ mL/kg}$ ) of intravenous fluid if the MAP is normal. Exceptions to this rule include patients with clinical dehydration or high fluid losses such as in burns, diabetes emergencies (see Ch. 21) and diabetes insipidus (Ch. 20), where fluid management should be guided by local protocols.

### Diagnosis and management

Further assessment and management of oliguria are explained on page 566. Two other important causes of renal failure in the inpatient population are abdominal compartment syndrome and rhabdomyolysis.

### Abdominal compartment syndrome

Abdominal compartment syndrome occurs when raised pressure within the abdomen reduces perfusion to the abdominal organs. It is most commonly seen in surgical patients, but can occur in medical conditions with extreme fluid retention such as liver cirrhosis. When it is suspected, intra-abdominal pressure can be monitored via a pressure transducer connected to a urinary catheter (following instillation of  $25 \text{ mL}$  of  $0.9\%$  saline into the bladder). Values over  $20 \text{ mmHg}$  suggest abdominal compartment syndrome is present. Urgent measures should be taken to reduce the pressure, such as decompression of the stomach, bladder and peritoneum if ascites is present. If conservative measures fail, a laparostomy can be considered.

### Rhabdomyolysis

Rhabdomyolysis occurs when there is an injury to a large volume of skeletal muscle, usually because a single limb or muscle compartment has been ischaemic for a prolonged period. It can also occur following trauma and crush injury or after over-exertion of muscles. Over-exertion can occur after intense physical exercise or as part of a medical condition that causes widespread muscular activity, such as malignant hyperpyrexia or neuroleptic malignant syndrome. A creatine kinase (CK) level of  $> 1000 \text{ U/L}$  is highly suggestive, although it can rise to tens of thousands in severe cases. Management should focus on identification and correction of the underlying cause and support for multi-organ dysfunction. Forced alkaline diuresis (using intravenous bicarbonate infusion and furosemide) can be used to maintain a good flow of less acidic fluid within the renal tubules and reduce myoglobin precipitation.

## Disorders causing critical illness

### Sepsis and the systemic inflammatory response

Sepsis is one of the most common causes of multi-organ failure. Sepsis requires the presence of infection with a resultant systemic inflammatory state; organ dysfunction occurs from a combination of the two processes. The definition of sepsis has undergone various iterations and

### 9.32 Definitions of sepsis and septic shock\*

#### Sepsis

Patients with suspected infection who have two or more of:

- *Hypotension* – systolic blood pressure < 100 mmHg
- *Altered mental status* – Glasgow Coma Scale score ≤ 14
- *Tachypnoea* – respiratory rate ≥ 22 breaths/min

Sepsis can also be diagnosed by suspected infection and an increase of ≥ 2 points on the Sequential Organ Failure Assessment (SOFA) score (Box 9.55).

#### Septic shock

A subset of sepsis with underlying circulatory or cellular/metabolic abnormalities associated with a substantially increased mortality:

- Sepsis and both of (after fluid resuscitation):
  1. Persistent hypotension requiring vasopressors to maintain a MAP > 65 mmHg
  2. Serum lactate > 2 mmol/L (18 mg/dL)

(MAP = mean arterial pressure)

\*From the Third International Consensus Definitions for Sepsis and Septic Shock (Sepsis-3).

there is still a lack of consensus as to the exact wording that best reflects this complex, multisystem process (Box 9.32).

### Aetiology and pathogenesis

To understand how an infection can lead to progressive multi-organ failure, it is essential to have a grasp of the pathophysiology.

#### Initiation of the inflammatory response

The process begins with infection in one part of the body that triggers a localised inflammatory response. Appropriate source control and a competent immune system will, in most cases, contain the infection at this stage. However, if certain factors are present, the infection may become systemic. The causative factors are not fully elucidated but probably include:

- a genetic predisposition to sepsis
- a large microbiological load
- high virulence of the organism
- delay in source control (either surgical or antimicrobial)
- resistance of the organism to treatment
- patient factors (immune status, nutrition, frailty).

Mediators are released from damaged cells (called ‘alarmins’) and these, coupled with direct stimulation of immune cells by the molecular patterns of the microorganism, trigger the inflammatory response. An example of such direct stimulation is that of lipopolysaccharide, which is found on the surface of Gram-negative bacteria. It strongly stimulates an immune response and is commonly used in research settings to initiate a septic cascade.

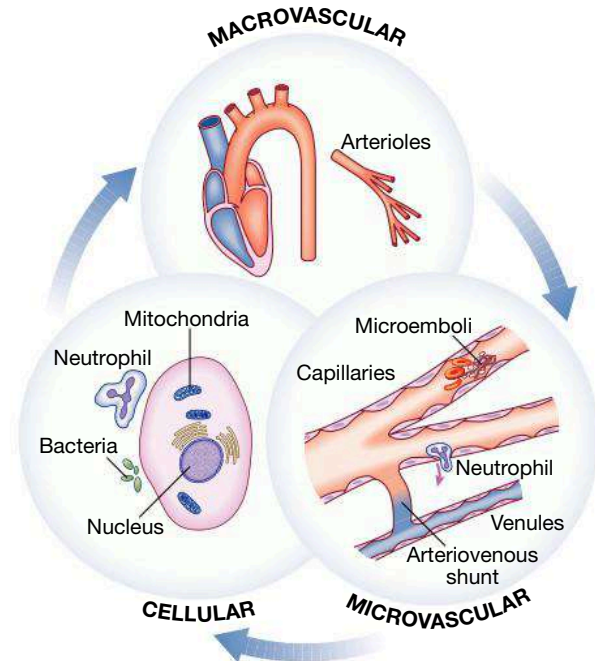

Viral and fungal infections can cause a syndrome that is clinically indistinguishable from bacterial sepsis. Likewise, numerous non-infective processes, such as pancreatitis, burns, trauma, major surgery and drug reactions, can cause alarmins to be released and initiate the process of systemic inflammation.

#### Propagation of the inflammatory response

Once activated, immune cells such as macrophages release the inflammatory cytokines interleukin-2 (IL-2), IL-6 and tumour necrosis factor alpha, which, in turn, activate neutrophils. Activated neutrophils express adhesion factors and release various other inflammatory and toxic substances; the net effects are vasodilatation (via activation of inducible nitric oxide synthase enzymes) and damage to the endothelium. Neutrophils migrate into the interstitial space; fluid and plasma proteins will also leak through the damaged endothelium, leading to oedema and intravascular fluid depletion.

#### Activation of the coagulation system

Damaged endothelium triggers the coagulation cascade (via tissue factor, factor VII, and reduced activity of proteins C and S) and thrombus forms within the microvasculature. A vicious circle of endothelial injury,

**Fig. 9.13 Pathophysiology of organ damage in sepsis.** *Macrovascular.* Severe hypovolaemia, vasodilatation or septic cardiomyopathy can reduce oxygen delivery, causing tissue hypoxia. Paradoxically, most patients with sepsis have an increased cardiac output and oxygen delivery. *Microvascular.* Tissue injury can occur from hypoxia secondary to microvascular injury and thrombosis. Damaged epithelium permits neutrophils, proteins and fluid to leak out. *Shunting.* Organs fail in sepsis despite supranormal blood flow. It is likely that arteriovenous shunt pathways exist within vascular beds; these shunts open up in septic shock. *Cellular.* Cells are damaged by a number of mechanisms in sepsis: (1) direct injury by microorganisms; (2) injury from toxins produced by immune cells, e.g. oxygen free radicals; (3) mitochondrial injury causing cytopathic hypoxia – cells are unable to metabolise oxygen; (4) apoptosis – if the cell injury is sufficient, caspase enzymes are activated within the nucleus and programmed cell death occurs; (5) hypoxia from micro- and macrovascular pathology.

intravascular coagulation and microvascular occlusion develops, causing more tissue damage and further release of inflammatory mediators. In severe sepsis, intravascular coagulation can become widespread. This is referred to as disseminated intravascular coagulation (DIC) and usually heralds the onset of multi-organ failure. Specific aspects of the diagnosis and management of DIC are discussed on page 988.

#### Organ damage from sepsis

Any and all organs may be injured by severe sepsis. The pathological mechanisms are shown in Figure 9.13.

#### Lactate physiology

Lactate is an excellent biomarker for the severity of sepsis. Hyperlactataemia (serum lactate > 2.4 mmol/L or 22 mg/dL) is used as a marker of severity. Figure 9.14 explains the physiology of hyperlactataemia; it is caused by all types of shock and therefore is not specific to sepsis. A lactate level of > 8 mmol/L (72 mg/dL) is associated with an extremely high mortality and should trigger immediate escalation. Measures to optimise oxygen delivery should be sought, and the adequacy of resuscitation measured by lactate clearance.

#### The anti-inflammatory cascade

As the inflammatory state develops, a compensatory anti-inflammatory system is activated involving the release of anti-inflammatory cytokines such as IL-4 and IL-10 from immune cells. While such mechanisms are necessary to keep the inflammatory response in check, they may lead to a period of immunosuppression after the initial septic episode. Patients

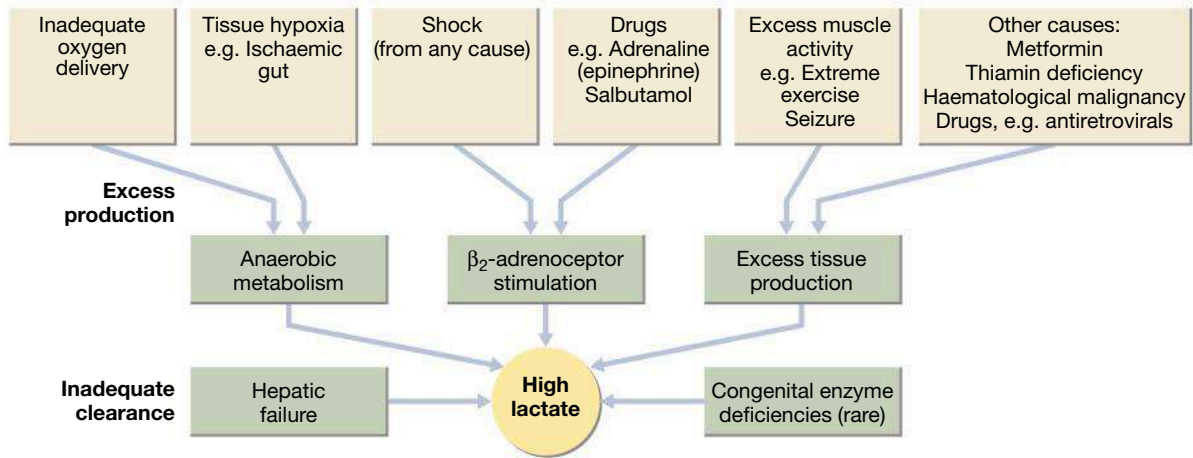

Fig. 9.14 Physiology of hyperlactataemia.

recovering from severe sepsis are prone to developing secondary infections due to a combination of this immunosuppression and the presence of indwelling devices.

### Management

The most important action is to consider sepsis as the cause of a patient's deterioration. Aligned to this is the requirement to consider other diagnoses that could be causing the presentation, such as haemorrhage, PE, anaphylaxis or a low cardiac output state.

### Resuscitation in sepsis

General resuscitative measures are discussed on page 208. Early resuscitation can be aided by following the requirements of the 'Sepsis Six' (Box 9.33). Red cell transfusion should be used to target a haemoglobin concentration of 70–90 g/L. Albumin 4% can be used as colloid solution and has the theoretical benefit of remaining in the intravascular space for longer than crystalloid. Early intubation is recommended in severe cases to facilitate further management and reduce oxygen demand.

Appropriate antibiotics should be administered as early as possible (Box 9.34). Specific points in the history should be reviewed, such as underlying immune system status, risk factors for human immunodeficiency virus (HIV) and contacts with highly transmissible infections such as tuberculosis, pertussis or COVID-19. Immunocompromised patients will be susceptible to a far broader spectrum of infectious microorganisms (p. 268). The antibiotic choice will depend on local patterns of resistance, patient risk factors and the likely source of infection. Information on likely organisms and appropriate antibiotics can be found on pages 113 and 271). Microbiological samples (such as blood cultures, urine or CSF) should be taken, but this should not delay antibiotic administration, if obtaining samples is difficult.

### Early source control

Source control requires an accurate diagnosis; urgent investigations should be performed as soon as physiological stability has been established. A CT scan of the chest and abdomen with contrast is a high-yield test in this context. Specific actions may be required to control infection, such as drainage of an abscess or surgical débridement/resection of infected and/or necrotic tissue. Removal of potentially infected urine catheters or venous/arterial catheters should be promptly undertaken. Infected prosthetic devices, e.g. joint replacements, can be particularly challenging and require early specialist input.

### Noradrenaline (norepinephrine) for refractory hypotension

Central venous access should be established early in the resuscitation process and a noradrenaline infusion commenced. If there is severe hypotension, it is not necessary to wait until 30 mL/kg of fluid has been administered before commencing noradrenaline; early vasopressor use

### 9.33 The 'Sepsis Six'\*

- Deliver high-flow oxygen
- Take blood cultures
- Administer intravenous antibiotics
- Measure serum lactate and send full blood count
- Start intravenous fluid replacement
- Commence accurate measurement of urine output

\*International recommendations for the immediate management of suspected sepsis from the Surviving Sepsis Campaign (all to be delivered within 1 hr of the initial diagnosis of sepsis).

### 9.34 Early administration of antibiotics in suspected sepsis

- Broad-spectrum antibiotics should be administered as soon as possible after sepsis is suspected.
- Every hour of delayed treatment is associated with a 5%–10% increase in mortality.

### 9.35 Central and mixed venous oxygen saturations

- Saturation of venous blood is sampled from the right atrium or superior vena cava (central) or pulmonary artery (mixed venous).
- Both values reflect the balance of supply and demand of oxygen to the tissues.
- Mixed venous oxygen saturation is a measure of whole-body supply and demand of oxygen; central venous oxygen saturation measures the supply and demand of oxygen from the upper body. Normal mixed venous oxygen saturation is 70%. Lower values than this suggest inadequate oxygen delivery.
- Central venous oxygen saturation is more variable, depending on whether the patient is awake or anaesthetised, but a value of 70% is considered normal.
- Where cytopathic hypoxia occurs, oxygen extraction is impaired and the central and mixed venous oxygen saturations may be > 80%. This is often a poor prognostic sign.

may improve the outcome from acute kidney injury. Measurement of central and mixed venous oxygen saturations may provide additional prognostic information (Box 9.35).

### Other therapies for refractory hypotension

Refractory hypotension is due to either inadequate cardiac output or inadequate systemic vascular resistance (vasoplegia). When vasoplegia is suspected, it may be necessary to add vasopressin (antidiuretic hormone, ADH). This is a potent vasoconstrictor that may be used to augment noradrenaline (norepinephrine) in achieving an acceptable MAP.

### 9.36 Sepsis mimics

- Pancreatitis
- Drug reactions – e.g. reactions to immunotherapy
- Widespread vasculitis – catastrophic antiphospholipid syndrome, Goodpasture's disease
- Autoimmune diseases – inflammatory bowel disease, rheumatoid arthritis, systemic lupus erythematosus
- Malignancy – carcinoid syndrome
- Haematological conditions – haemophagocytic syndrome, diffuse lymphoma, thrombotic thrombocytopenic purpura

Intravenous glucocorticoids are also commonly used in refractory hypotension. There is little evidence that they improve the overall outcome, but they do lead to a more rapid reversal of the shocked state. There is a small increased risk of secondary infection following glucocorticoid use.

#### Septic cardiomyopathy

The myocardium can be affected by the septic process, presenting as either acute left or right ventricular dysfunction. A bedside echocardiogram is particularly useful to confirm the diagnosis, as ECG changes are usually non-specific. Dobutamine or adrenaline (epinephrine) can be used to augment cardiac output, and intravenous calcium should be replaced if ionised calcium is low.

Other interventions such as intravenous bicarbonate in profound metabolic acidosis, high-volume haemofiltration/haemodialysis and extracorporeal support are sometimes used, but currently lack evidence of benefit.

#### Review of the underlying pathology

While sepsis is the most common cause of acute systemic inflammation, up to 20% of patients initially treated for sepsis will have a non-infectious cause: that is, a sepsis mimic (Box 9.36). These conditions should be considered where the clinical picture is not typical, no source of sepsis can be found, or the inflammatory response seems excessive in the context of local infection. Early reconsideration of the diagnosis of sepsis is crucial, as many of the 'sepsis mimics' offer a finite time window for specific intervention, after which irreversible organ damage will have occurred.

## Acute respiratory distress syndrome

### Aetiology and pathogenesis

Acute respiratory distress syndrome (ARDS) is a diffuse neutrophilic alveolitis caused by a range of conditions and characterised by bilateral radiographic infiltrates and hypoxaemia (Box 9.37). Activated neutrophils are sequestered into the lungs and capillary permeability is increased, with damage to cells within the alveoli. The pathophysiology is part of the inflammatory spectrum described in 'Sepsis' above, and the triggers are similar: infective and non-infective inflammatory processes. These processes result in exudation and accumulation of protein-rich cellular fluid within alveoli and the formation of characteristic 'hyaline membranes'. Local release of cytokines and chemokines by activated macrophages and neutrophils results in progressive recruitment of inflammatory cells. Secondary effects include loss of surfactant and impaired surfactant production. The net effect is alveolar collapse and reduced lung compliance, most marked in dependent regions of the lung (mainly dorsal in supine patients). The affected airspaces become fluid-filled and can no longer contribute to ventilation, resulting in hypoxaemia (due to increased pulmonary shunt) and hypercapnia (due to inadequate ventilation in some areas of the lung): that is, ventilation–perfusion mismatch.

### Diagnosis and management

ARDS can be difficult to distinguish from fluid overload or cardiac failure. Classic chest X-ray and CT appearances are shown in Figures 9.15 and 9.16, respectively. Occasionally, conditions may

### 9.37 Berlin definition of ARDS

- Onset within 1 week of a known clinical insult, or new or worsening respiratory symptoms
- Bilateral opacities on chest X-ray, not fully explained by effusions, lobar/lung collapse or nodules
- Respiratory failure not fully explained by cardiac failure or fluid overload. Objective assessment (e.g. by echocardiography) must exclude hydrostatic oedema if no risk factor is present
- Impaired oxygenation (see Box 9.38)

**Fig. 9.15** Chest X-ray in acute respiratory distress syndrome (ARDS). Note bilateral lung infiltrates, pneumomediastinum, pneumothoraces with bilateral chest drains, surgical emphysema and fractures of the ribs, right clavicle and left scapula.

**Fig. 9.16** CT scan of the thorax in a patient with severe ARDS. Note the pathology is mainly in the dorsal (dependent) parts of the lung.

present in a similar way to ARDS but respond to alternative treatments; an example of this might be a glucocorticoid-responsive interstitial pneumonia (p. 533). There is debate within the intensive care community as to whether severe COVID-19 pneumonitis causes ARDS. Clinically and pathologically COVID-19 does appear to be a separate entity in which glucocorticoids may be useful. However, glucocorticoids

### 9.38 Determining the severity of ARDS

Severity of hypoxaemia is calculated using a  $Pa/FiO_2$  ratio. This is a number calculated by using the  $PaO_2$  from an arterial blood gas measurement divided by the fraction of inspired oxygen ( $FiO_2$ , expressed as a fraction).

For example, a patient with a  $PaO_2$  of 10 kPa (75 mmHg) on 50% oxygen, i.e.  $FiO_2$  of 0.5, would have a  $Pa/FiO_2$  ratio of 20 kPa (150 mmHg). This would be defined as moderately severe ARDS, if the other Berlin criteria were met (see [Box 9.37](#)). All measurements should be taken on a minimum of 5 cmH<sub>2</sub>O of PEEP or CPAP.

- Mild: 40–26.6 kPa (300–200 mmHg)
- Moderate: 26.6–13.3 kPa (200–100 mmHg)
- Severe:  $\leq 13.3$  kPa ( $\leq 100$  mmHg)

(CPAP = continuous positive airway pressure; PEEP = positive end-expiratory pressure)

remain of unproven benefit in ARDS from other causes. Safely reaching an accurate pathological diagnosis of respiratory failure is one of the key research areas within intensive care.

Management of ARDS is supportive, including use of lung-protective mechanical ventilation, inducing a negative fluid balance and treating the underlying cause. Establishing the severity of ARDS ([Box 9.38](#)) is useful, as severe disease will require more proactive management such as prone positioning or extracorporeal membrane oxygenation (ECMO; [Fig. 9.24](#)).

## Acute circulatory failure (cardiogenic shock)

### Definition and aetiology

Cardiogenic shock is defined as hypoperfusion due to inadequate cardiac output or, more technically, a cardiac index of  $<2.2$  L/min/m<sup>2</sup> (see [Box 9.47](#)). While cardiogenic shock is the final common pathway of many disease processes (e.g. sepsis, anaphylaxis, haemorrhage), the important primary causes of acute heart failure or cardiogenic shock ([Fig. 9.17](#)) are described here.

### Myocardial infarction

In the majority of cases, cardiogenic shock following acute MI is due to left ventricular dysfunction. However, it may also be due to infarction of the right ventricle, or a variety of mechanical complications, including tamponade (due to infarction and rupture of the free wall), an acquired ventricular septal defect (due to infarction and rupture of the septum) and acute mitral regurgitation (due to infarction or rupture of the papillary muscles).

Severe myocardial systolic dysfunction causes a fall in cardiac output, BP and coronary perfusion pressure. Diastolic dysfunction causes a rise in left ventricular end-diastolic pressure, pulmonary congestion and oedema, leading to hypoxaemia that worsens myocardial ischaemia. This is further exacerbated by peripheral vasoconstriction. These factors combine to create the 'downward spiral' of cardiogenic shock ([Fig. 9.18](#)). Hypotension, oliguria, delirium and cold, clammy peripheries are the manifestations of a low cardiac output, whereas breathlessness, hypoxaemia, cyanosis and inspiratory crackles at the lung bases are typical features of pulmonary oedema. If necessary, a Swan–Ganz catheter can be used to measure the pulmonary artery pressures and cardiac output ([Fig. 9.25](#)). These findings can be used to categorise patients with acute MI into four haemodynamic subsets ([Box 9.39](#)) and titrate therapy accordingly.

In cardiogenic shock associated with acute MI, immediate percutaneous coronary intervention should be performed. The viable myocardium surrounding a fresh infarct may contract poorly for a few days and then recover. This phenomenon is known as myocardial stunning and means that acute heart failure should be treated intensively because overall cardiac function may subsequently improve.

### Acute massive pulmonary embolism

Massive PE may complicate leg or pelvic vein thrombosis and usually presents with sudden collapse. The clinical features and treatment are

discussed on page 546. Bedside echocardiography may demonstrate a small, under-filled, vigorous left ventricle with a dilated right ventricle; it is sometimes possible to see thrombus in the right ventricular outflow tract or main pulmonary artery. In practice, it can be difficult to distinguish massive PE from a right ventricular infarct on transthoracic echocardiogram. CT pulmonary angiography usually provides a definitive diagnosis.

### Acute valvular pathology, aortic dissection and cardiac tamponade

These conditions should be considered in an undifferentiated presentation of shock. The diagnosis and management of these conditions is discussed in [Chapter 16](#).

## Cardiac arrest

Cardiac arrest is the cessation of functional cardiac contraction and is the final common pathway in death from any pathology. In the clinical context, cardiac arrest refers to the sudden loss of cardiac output that prompts an emergency response. Pathogenesis, prognosis and management of in-hospital and out-of-hospital cardiac arrest are subtly different; however, the basic principles of cardiopulmonary resuscitation (CPR) are to maintain forward flow of oxygenated blood, correct the causative factor and restore spontaneous circulation.

### Out-of-hospital cardiac arrest (OHCA)

This is the sudden and complete loss of cardiac output occurring in the community. The clinical diagnosis is based on the victim being unconscious and pulseless; breathing may take some time to stop completely after cardiac arrest. Death is virtually inevitable, unless effective treatment is given promptly.

### Pathogenesis

Cardiac arrest may be caused by ventricular fibrillation ([Fig. 9.19](#)), pulseless ventricular tachycardia (see [Ch. 16](#)), asystole or pulseless electrical activity. Myocardial ischaemia is the most common trigger of OHCA. This can be due to an acute infarct, acute or chronic coronary insufficiency, post-infarct ventricular scarring or structural cardiac disease (cardiomyopathy, aortic stenosis). Ventricular fibrillation can occur in the absence of recognised structural abnormalities, e.g. congenital syndromes such as Brugada syndrome. Occasionally, sudden cardiac death can occur from an acute mechanical catastrophe such as cardiac rupture or aortic dissection. The causes are listed in [Chapter 16](#), [Box 16.7](#).

### Survivors of OHCA

The 'Chain of Survival' ([Fig. 9.20](#)) refers to the sequence of events that is necessary to maximise the chances of a cardiac arrest victim surviving. Survival is most likely if all links in the chain are strong: that is, if the arrest is witnessed, help is called immediately, basic life support is administered by a trained individual, the emergency medical services respond promptly, and defibrillation is achieved within a few minutes. CPR from bystanders, often assisted by ambulance service telephone dispatchers, is crucial. Good training in both basic and advanced life support is essential and should be maintained by regular refresher courses. Automated external defibrillators (AEDs) are increasingly available in public places, particularly where traffic congestion may impede the response of emergency services, and should be used as soon as possible. Designated individuals can respond to a cardiac arrest using basic life support and an automated external defibrillator.

For OHCA, survival rates of approximately 10% have been reported internationally. When type I myocardial infarction [Box 16.47](#) is the suspected pathology, early coronary revascularisation should be considered. Those with reversible causes, such as exercise-induced ischaemia or aortic stenosis, should have the underlying cause treated if possible. Survivors of a ventricular tachycardia or ventricular fibrillation arrest, in whom no reversible cause can be identified, may be at risk of another episode and should be considered for an implantable cardiac defibrillator (p. 418) and anti-arrhythmic drug therapy.

Fig. 9.17 Some common causes of cardiogenic shock. (LA = left atrium; LV = left ventricle; PA = pulmonary artery; RA = right atrium; RV = right ventricle)

Fig. 9.18 The downward spiral of cardiogenic shock.

9.39 Acute myocardial infarction: haemodynamic subsets		
Cardiac output	Pulmonary oedema	
	No	Yes
Normal	Good prognosis and requires no treatment for heart failure	Due to moderate left ventricular dysfunction. Treat with vasodilators and diuretics
Low	Due to right ventricular dysfunction or concomitant hypovolaemia. Give fluid challenge and consider pulmonary artery catheter to guide therapy	Extensive myocardial infarction and poor prognosis. Consider intra-aortic balloon pump, vasodilators, diuretics and inotropes

### In-hospital cardiac arrest (IHCA)

Historically, outcomes from IHCA were extremely poor. However, with appropriate anticipatory care planning and prompt intervention of hospital resuscitation teams, outcomes can be significantly better than for OHCA.

#### Pathogenesis

Although primary cardiac causes are the most common cause of IHCA, additional factors such as organ failure, sepsis or respiratory decompensation are often more pertinent. Correction of hypoxaemia with early tracheal intubation and ventilation is therefore of higher importance in this

group than in OHCA, provided it can be achieved without interruption of chest compressions.

**Clinical assessment and management**

**Basic life support**

When a patient with suspected cardiac arrest is encountered, the ABCDE approach to management should be followed; this involves prompt assessment and restoration of the **A**irway, maintenance of ventilation using rescue **B**reathing ('mouth-to-mouth' breathing), and maintenance of the **C**irculation using chest compressions; **D**isability, in resuscitated patients, refers to assessment of neurological status, and **E**xposure entails removal of clothes to enable defibrillation, auscultation of the chest and assessment for a rash caused by anaphylaxis, for injuries and so on (Fig. 9.21). The term basic life support (BLS) encompasses manoeuvres that aim to maintain a low level of circulation until more definitive treatment with advanced life support can be given. Chest compression-only ('hands-only') CPR is easier for members of the public to learn and administer, and is now advocated in public education campaigns.

**Advanced life support**

Advanced life support (ALS) (Fig. 9.22) aims to restore normal cardiac rhythm by defibrillation when the cause of cardiac arrest is a tachyarrhythmia, or to restore cardiac output by correcting other reversible causes of cardiac arrest. The initial priority is to assess the patient's cardiac rhythm by attaching a defibrillator or monitor. Once this has been done, treatment should be instituted based on the clinical findings. Only a minority of patients will have a shockable rhythm at the commencement of resuscitation.

Ventricular fibrillation or pulseless ventricular tachycardia should be treated with immediate defibrillation. Defibrillation is more likely to be effective if a biphasic shock defibrillator is used, where the polarity of the shock is reversed midway through its delivery. Defibrillation is usually administered using a 150 Joule biphasic shock, and CPR resumed immediately for 2 minutes without attempting to confirm restoration of a pulse, because restoration of mechanical cardiac output rarely occurs immediately after successful defibrillation. If, after 2 minutes, a pulse is not restored, a further biphasic shock of 150–200J should be given. Thereafter, additional biphasic shocks of 150–200J are given every 2 minutes after each cycle of CPR. During resuscitation, adrenaline (epinephrine, 1 mg IV) should be given every 3–5 minutes and consideration

given to the use of intravenous amiodarone, especially if ventricular fibrillation or ventricular tachycardia re-initiates after successful defibrillation.

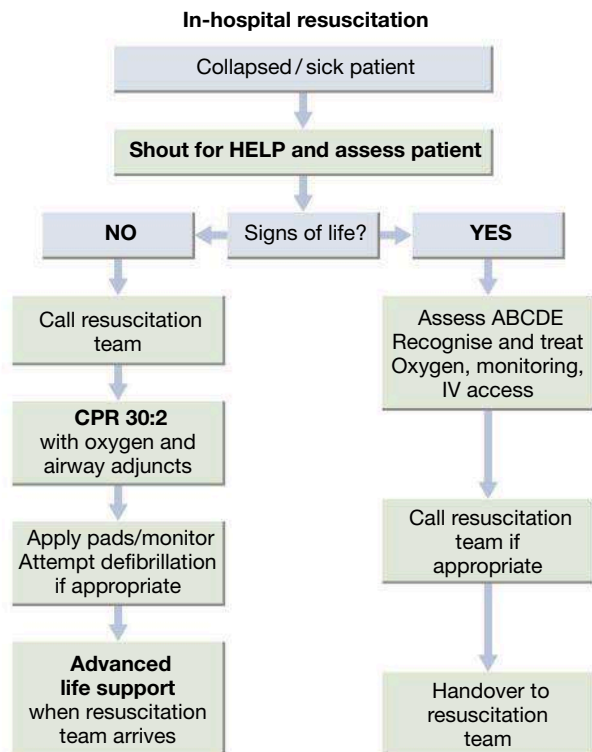

Ventricular fibrillation of low amplitude, or 'fine VF', may mimic asystole. If asystole cannot be confidently diagnosed, the patient should be treated for VF and defibrillated. Bedside echocardiography can be a useful clinical aid. The subcostal views can frequently be obtained without detriment to CPR quality, and can identify cardiac structural abnormalities such as an enlarged right heart in pulmonary embolism, aortic stenosis or ongoing fine VF. Refractory VF can be amenable to supplementary drugs (e.g. lidocaine, magnesium, procainamide) or alternative ways of using the defibrillator, e.g. antero-posterior pad placement.

If an electrical rhythm is observed that would be expected to produce a cardiac output, 'pulseless electrical activity' is present. Pulseless electrical activity should be treated by continuing CPR and adrenaline (epinephrine) administration while seeking causes. Asystole should be treated similarly although prolonged asystole has an extremely poor prognosis.

There are many potentially reversible causes of cardiac arrest; the main ones can be remembered as a list of four Hs and four Ts (see Fig. 9.22). In specialist centres and in appropriate candidates, the use of extracorporeal life support (has been used in cardiac arrest with good

**Fig. 9.19** Ventricular fibrillation. A bizarre chaotic rhythm, initiated in this case by two ventricular ectopic beats in rapid succession.

**Fig. 9.21** Algorithm for adult basic life support. For further information, see [www.resus.org.uk](http://www.resus.org.uk). (CPR = cardiopulmonary resuscitation) From Resuscitation Council (UK) guidelines: <https://www.resus.org.uk/resuscitation-guidelines/in-hospital-resuscitation/>.

**Fig. 9.20** The Chain of Survival in cardiac arrest. (ALS = advanced life support; CPR = cardiopulmonary resuscitation)

effect. However, this is not generally available outside of large urban centres. The use of automated chest compression devices is becoming more common and their use should be considered in patients in whom a prolonged resuscitation is expected (e.g. when thrombolytic has been administered or in profound hypothermia). Injuries from CPR are common; their management is summarised in the section on 'Complications and outcomes of critical illness'.

## Post cardiac arrest

The majority of cardiac arrest survivors will need a period of time in intensive care to achieve physiological stability, identify and manage the underlying cause of the arrest, and optimise neurological recovery.

### Acute management

A MAP of >70mmHg should be maintained to optimise cerebral perfusion. Shock is common following return of spontaneous circulation (ROSC) and is caused by a combination of the underlying condition leading to the arrest, myocardial stunning and a post-arrest vasodilated state. Support

with inotropes, vasopressors and occasionally mechanical support from an intra-aortic balloon pump or venous-arterial ECMO (Fig. 9.24) may be required. Specific cardiac interventions and their indications are described in Chapter 16. Other physiological targets are listed in Box 9.40.

### Prognosis

Predicting which patients will not recover from the brain injury sustained at the time of cardiac arrest is very difficult. Certain features suggest that the outcome will be poor: for example, the absence of pupillary and corneal reflexes, absence of a motor response and persistent myoclonic jerking.

Tools to assist prognostication following cardiac arrest are shown in Box 9.41. The clinician should, where feasible, delay prognostication until a period of 72 hours of targeted temperature management has been completed. The bilateral absence of the 'N20' spike on the somatosensory evoked potential is the most specific test to predict irrecoverable brain injury. This test is performed by administering an electrical impulse over a peripheral nerve and recording the electrical impulses measured by the scalp electrodes overlying the part of the brain expected to receive the

**Fig. 9.22** Algorithm for adult advanced life support. For further information, see [www.resus.org.uk](http://www.resus.org.uk). (CPR = cardiopulmonary resuscitation; PEA = pulseless electrical activity; VF = ventricular fibrillation; VT = ventricular tachycardia) From Resuscitation Council (UK) guidelines: <https://www.resus.org.uk/resuscitation-guidelines/adult-advanced-life-support/>.

**9.40 Physiological targets following a return of spontaneous circulation (ROSC)**

- **Temperature management.** Facilitate maintenance of temperature at 36°C and avoidance of pyrexia using a cooling blanket. This should be continued for 72 hrs. Muscle relaxants may be required to prevent shivering.
- **Blood pressure management.** Aim for a MAP of at least 70 mmHg and a systolic blood pressure of > 120 mmHg.
- **Glucose control.** Control the glucose to 6–10 mmol/L (108–180 mg/dL).
- **Normal CO<sub>2</sub>** (4.5–6 kPa, 33–45 mmHg) and oxygen saturation (94%–98%). Avoid both hypoxaemia and hyperoxia.

**9.41 Prognostication after cardiac arrest: predictors of poor neurological recovery****Coexisting problems**

- Multi-organ failure
- Significant comorbidities

**Clinical**

- Persisting and generalised myoclonus
- Absence of pupillary or corneal reflexes
- Poor motor response (absent or extensor response)

**Biochemical**

- Neuron-specific enolase > 33 µg/L

**Imaging**

- CT showing loss of grey–white differentiation
- Focal cause or consequence of cardiac arrest, e.g. subarachnoid haemorrhage

**Electrophysiology**

- EEG patterns may suggest brain injury, e.g. burst suppression
- Somatosensory evoked potentials – bilateral absence of the N20 spike (recorded from scalp electrodes from cutaneous electrical impulse over the median nerve)

impulse. Where this is not available, prognostication based on all other available information, along with the perceived wishes relating to the level of disability the individual would be prepared to accept, should allow a decision regarding ongoing treatment to be made. Where there is doubt, more time should be given to allow assessment of neurological recovery.

**Other causes of multi-organ failure**

As previously discussed, sepsis is the most common cause of multi-organ failure. However, multi-organ failure secondary to single organ dysfunction, such as cardiac failure, liver failure, renal failure or respiratory failure, is also common. The multisystem insult in these disease processes goes beyond the direct biochemical damage and tissue hypoxia caused by the primary organ dysfunction. It probably reflects cellular signalling pathways and the release of other systemic toxins by the failing organ, referred to as organ ‘crosstalk’.

Multi-organ failure can also be caused by a physiological insult that damages a wide variety of cells in different organs, including toxins from extrinsic sources such as envenomation and intrinsic sources such as myoglobin in rhabdomyolysis (p. 198). Multi-organ failure can also be caused by profound physical injury to cells from processes such as nuclear radiation, heat exposure or blast trauma.

**Critical care medicine****Decisions around intensive care admission**

Being a patient in intensive care is seldom a pleasant experience. The interventions are usually painful and the loss of liberties that are normally taken for granted can be devastating. While much of the unpleasant

**9.42 Critical illness in the context of congenital conditions**

- **Longer survival:** there are many congenital conditions that would, in the past, have been fatal in childhood, but now patients survive into adulthood. Decision-making can be difficult when the adolescent has impaired decision-making capacity.
- **Parental views:** in such circumstances, the views of the parent or legal guardian become paramount.
- **Goals of care:** often a detailed explanation of what is, and is not, achievable in intensive care allows the direction of care to be switched to palliative when life expectancy is poor and quality of life is severely impaired.
- **Decision-making:** such conversations may require input from experts in the patient's congenital condition(s), and advanced decision-making regarding ICU admission should be encouraged whenever patients and families feel able to discuss such issues.

**9.43 Techniques to improve admission decision-making**

- **Always act in the best interests of the patient:** external influences are commonly present but these should be of only secondary importance.
- **Maximise patient capacity:** wherever possible, the patient should be involved in discussions of escalation and resuscitation status.
- **Communicate openly and honestly with the next of kin:** when communicating potential outcomes, it is best to use natural frequencies rather than percentages. For example, ‘If we had 100 patients with the same illness as your mother, only 10 would survive’ is easier for most people to understand than ‘there is a 90% chance of death’.
- **Reach mutual agreement with the next of kin:** it is rare for there to be discord between clinicians and family, and in most cases the most appropriate course of action is clear.
- **Seek additional opinions:** other clinicians involved in the care of the patient will provide useful input. The premise should be to err on the side of escalation where the most appropriate course of action is unclear. Where there is an unresolvable difference in opinion, a mediation process or court ruling may be required to make the final decision. Thankfully, this is a very infrequent occurrence.
- **Plan ahead:** advance planning in chronic, progressive disease can make the decision easier. Some health facilities use an escalation form, which specifies the interventions that should be offered or are acceptable to the patient. This can be useful as the binary decision of for/not for resuscitation fails to account for the array of interventions that can be performed before cardiac arrest occurs.

sensory and emotional experience can be modified with high-quality care and analgesia, there is a strong case that it can only be morally ‘right’ to admit a patient to intensive care if ‘the ends justify the means’. There must be a realistic hope that the patient will regain a quality of life that would be worth the pain and suffering that he or she will experience in intensive care. Few patients are able to comprehend fully what it means to be critically ill, so the physician should guide the process of determining who should be admitted to intensive care.

Selecting the appropriate level of intervention for an individual patient can be very difficult. The decision-making process should involve an assessment of the likelihood of reversibility of the disease, the magnitude of the interventions required, the underlying level of frailty, and the personal beliefs and wishes of the patient (commonly expressed through their next of kin).

As technology and science have improved, conditions that were previously regarded as terminal can now be supported and life can be considerably prolonged (Box 9.42). There have been several prominent examples of individuals who have received intensive care, but where an onlooker might have considered treatment to be futile owing to frailty, comorbidity or profound neurological injury. Such cases will, in part, shape the views and expectations of society, and it is unlikely that making decisions in this area will become any easier. Some suggested techniques to aid decision-making are listed in Box 9.43.

## Stabilisation and institution of organ support

In order to stabilise a critically unwell patient, the primary problem should be corrected as quickly as possible: for example, source control in sepsis and control of the bleeding point in haemorrhage. Immediate resuscitation and prioritisation of the safety of the patient are clearly important, but there is only a limited role for 'optimising' the patient if such measures may significantly delay a definitive treatment, such as laparotomy for a perforated viscus. In some cases, the definitive treatment is not readily apparent or treatments take time to have their full effect. In these cases, adequate organ support to stabilise the patient while the treatment is given becomes the main goal of care.

### Respiratory support

#### Non-invasive respiratory support

Non-invasive respiratory support provides a bridge between simple oxygen delivery devices and invasive ventilation. It can be used in patients who are in respiratory distress but do not have an indication for invasive ventilation, or in those who are not suitable for intubation and ventilation for chronic health reasons. Patients must be cooperative, able to protect their airway, and have the strength to breathe spontaneously and cough effectively. Clinicians should avoid using non-invasive respiratory support to prolong the dying process in irreversible conditions such as end-stage lung disease. Likewise, a failure to respond to treatment or further deterioration should trigger a decision regarding intubation, as delayed invasive ventilation in this context is associated with worse outcome.

#### High-flow nasal cannulae

High-flow nasal cannulae (HFNCs) are devices that provide very high gas flows of fully humidified oxygen and air. They offer distinct advantages over non-invasive ventilation (NIV) in selected patients, mainly those with type I respiratory failure (particularly pneumonia) who have not reached an indication for invasive ventilation. They allow patient comfort and increased expectoration while providing some degree of positive end-expiratory pressure (PEEP) and a high oxygen concentration that can be titrated to the  $SO_2$ .

#### Continuous positive pressure ventilation

Continuous positive pressure ventilation therapy involves the application of a continuous positive airway pressure (CPAP) throughout the patient's breathing cycle, typically 5–10 cmH<sub>2</sub>O. It helps to recruit collapsed alveoli and can enhance clearance of alveolar fluid. It is particularly effective at treating pulmonary atelectasis (which may be post-operative) and pulmonary oedema. It can be delivered using a simpler device than NIV, may be better tolerated and avoids compounding the hypocapnia that sometimes occurs in type I respiratory failure.

#### Non-invasive ventilation or bi-level ventilation

NIV provides ventilatory support via a tight-fitting nasal or facial mask. It can be delivered by using a simple bi-level ventilation (BiPAP) turbine ventilator, or an intensive care ventilator. These machines can deliver pressure at a higher level (approximately 15–25 cmH<sub>2</sub>O) for inspiration and a lower pressure (usually 4–10 cmH<sub>2</sub>O) to allow expiration. Ventilation can be spontaneous (triggered by a patient's breaths) or timed (occurring at a set frequency). Systems that synchronise with a patient's efforts are better tolerated and tend to be more effective in respiratory failure. Timed breaths are used for patients with central apnoea. NIV is the first-line therapy in patients with type II respiratory failure secondary to an acute exacerbation of COPD because it reduces the work of breathing and offloads the diaphragm, allowing it to recover strength. It is also useful in pulmonary oedema, obesity hypoventilation syndromes and some neuromuscular disorders. It should be initiated early, especially when severe respiratory acidosis secondary to hypercapnia is present. NIV can also be used to support selected patients with hypercapnia secondary to

#### 9.44 Optimising safety during intubation

- Intervene early in the disease process (once it has become clear that the disease trajectory is downward).
- Use a stable anaesthetic technique: low doses of sedative agents and rapidly acting paralytic agents.
- Remember that intubation should be performed by the most experienced operator available.
- Use techniques to optimise oxygenation and ventilation in the period around intubation, e.g. keeping non-invasive ventilation in situ for pre-oxygenation, manual ventilation via facemask while awaiting neuro-muscular blockade, and using a video-laryngoscope in an anticipated difficult intubation.
- When the history and epidemiology suggests risk of an airborne communicable disease, intubation should be performed in an isolated room with adequate ventilation and with as few staff present as possible. Intubation is an aerosol-generating procedure and all staff should wear appropriate personal protective equipment.

9

pneumonia, or during weaning from invasive ventilation, but its effectiveness in these contexts is less certain; early intubation or re-intubation is probably more beneficial.

### Intubation and intermittent positive pressure ventilation

Taking control of the respiratory system in a critically ill patient is one of the most significant and risky periods in a patient's journey. Critical incidents are common because the patient is often deteriorating rapidly and is exhausted. The potential for cardiovascular collapse is further exacerbated by the negatively inotropic and vasodilating drugs used to induce anaesthesia, and the period of apnoea invoked to facilitate intubation (Box 9.44).

The main aims of intermittent positive pressure ventilation (IPPV) are to avoid critical hypoxaemia and hypercapnia while minimising damage to the alveoli and encouraging the patient to breathe spontaneously once it is safe to do so. The determination of what constitutes *critical* will depend on the status of each patient. For example, a patient with raised ICP will have a strong indication for normocapnia (because hypercapnia increases ICP). Unfortunately, achieving the minute volumes required to maintain normocapnia can be harmful to the lungs.

#### Ventilator modes

Following intubation, most patients have a period of paralysis from the muscle relaxation. Mandatory ventilation is, therefore, required for a variable period, depending on the severity of the lung injury, the underlying disease process and the general condition of the patient. Mandatory ventilation means that the ventilator will deliver set parameters (either a set tidal volume or a set inspiratory pressure), regardless of patient effort. A physician can choose to support additional patient effort in between mandatory breaths with pressure support. This requires sufficient patient effort to 'trigger' the ventilator to deliver a synchronised breath, in time with the patient's own ventilation. Other parameters that should be considered when using mechanical ventilation are shown in Figure 9.23.

As a patient's illness resolves, or if the lung injury necessitating intubation is not severe, periods of spontaneous breathing with pressure support are commenced. While spontaneous breathing is preferable to mandatory ventilation modes, the shearing forces of patient effort can exacerbate lung injury in patients with severely damaged lungs. It is, therefore, important that a patient is permitted to breathe in a planned and controlled way.

#### Ventilator-induced lung injury

Every positive pressure breath causes cyclical inflation of alveoli followed by deflation. The resultant damage to alveoli occurs via several possible mechanisms:

- distending forces from the tidal volume, termed 'volutrauma'
- the pressure used to inflate the lung, referred to as 'barotrauma'

**Plateau pressure**

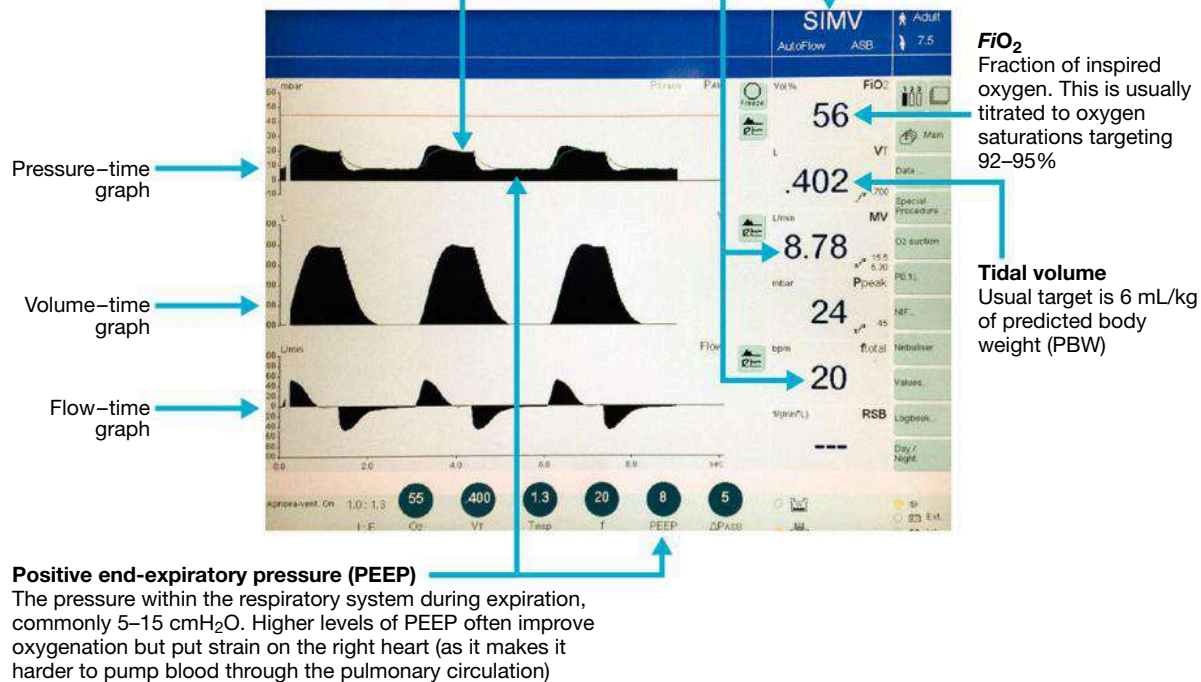

Airway pressure during an inspiratory hold. Keeping plateau pressure as low as possible above PEEP is the most protective strategy for the lungs

**Respiratory rate and minute volume**

Depend on the minute volume required to achieve the desired  $PCO_2$ , and whether the patient is breathing spontaneously. Rates are commonly 20–30 breaths/min

**Ventilator mode**

Mandatory, spontaneous, or mandatory with the ability to take spontaneous breaths (as shown here)

**Fig. 9.23** Settings to be considered when commencing mechanical ventilation.

- alveoli collapsing at the end of expiration, called ‘atelectotrauma’
- the release of inflammatory cytokines in response to cyclical distension, called ‘biotrauma’.

The threshold of injurious ventilation is unique to each patient. Moderate ventilator pressures and volumes used to ventilate healthy lungs may not cause ventilator-induced lung injury (VILI), but the same settings may cause significant VILI if delivered to a patient with lungs that are already damaged from another disease process.

Strategies that may reduce the incidence and severity of VILI include:

- *Permissive hypercapnia*. In the majority of patients who are ventilated for respiratory failure, it is preferable to tolerate moderate degrees of hypercapnia rather than strive for normal blood gases at the expense of VILI. For example, in a patient with isolated respiratory failure, a physician may choose to tolerate a  $PaCO_2$  of up to 10 kPa (75 mmHg), provided the  $H^+$  is  $< 63$  nmol/L (pH  $> 7.2$ ).
- *‘Open lung’ ventilation*. Maintaining a positive pressure within the airways at the end of expiration prevents atelectotrauma. This can be facilitated by the use of low tidal volumes and higher levels of PEEP (see Fig. 9.23). Recruitment manoeuvres (occasional short periods of sustained high airway pressures to open up alveoli that have collapsed) can reduce the incidence of VILI in patients who do not have ARDS.
- *Paralysis*. When respiratory failure is severe, patient effort may worsen VILI. An infusion of muscle relaxant can be used to moderate dyssynchrony with the ventilator.

## Advanced respiratory support

### Airway pressure release ventilation

Airway pressure release ventilation (APRV) is a mode of ventilation that lengthens the inspiratory time to the extreme, with a very short period of

time for expiration. It relies on spontaneous movement of the diaphragm from patient effort to facilitate the mixing of gas within the respiratory system during the long period in full inspiration, followed by a very short period of low pressure to allow passive expiration. It has not, however, been demonstrated to be superior to conventional modes of ventilation, but may have a role in some patients with moderate to severe ARDS.

### Prone positioning

In ARDS, the posterior parts of the lung lose airspaces due to atelectasis and inflammatory exudate. By placing patients on their front, the pattern of fluid distribution within the lung changes, and ventilation–perfusion matching is improved. This is used to enhance oxygenation in moderate to severe ARDS, and may have some disease-modifying effects as the dependent areas of the lung are changed periodically. Although there are risks associated with nursing a patient in the prone position, it is a widely used therapy. Patients are usually placed in the prone position for 12–24 hours and then rotated back to the supine position for a similar period. This cycle continues until there is evidence of resolving lung injury. Using prone positioning in the awake and cooperative patient on high-flow oxygen or CPAP may be a useful technique in some patients.

### Extracorporeal respiratory support

Sometimes, despite optimal invasive ventilation, it is not possible to maintain adequate oxygenation or prevent a profound respiratory acidosis. When a patient has a reversible cause of respiratory failure (or is a potential lung transplant recipient) and facilities are available, extracorporeal respiratory support should be considered.

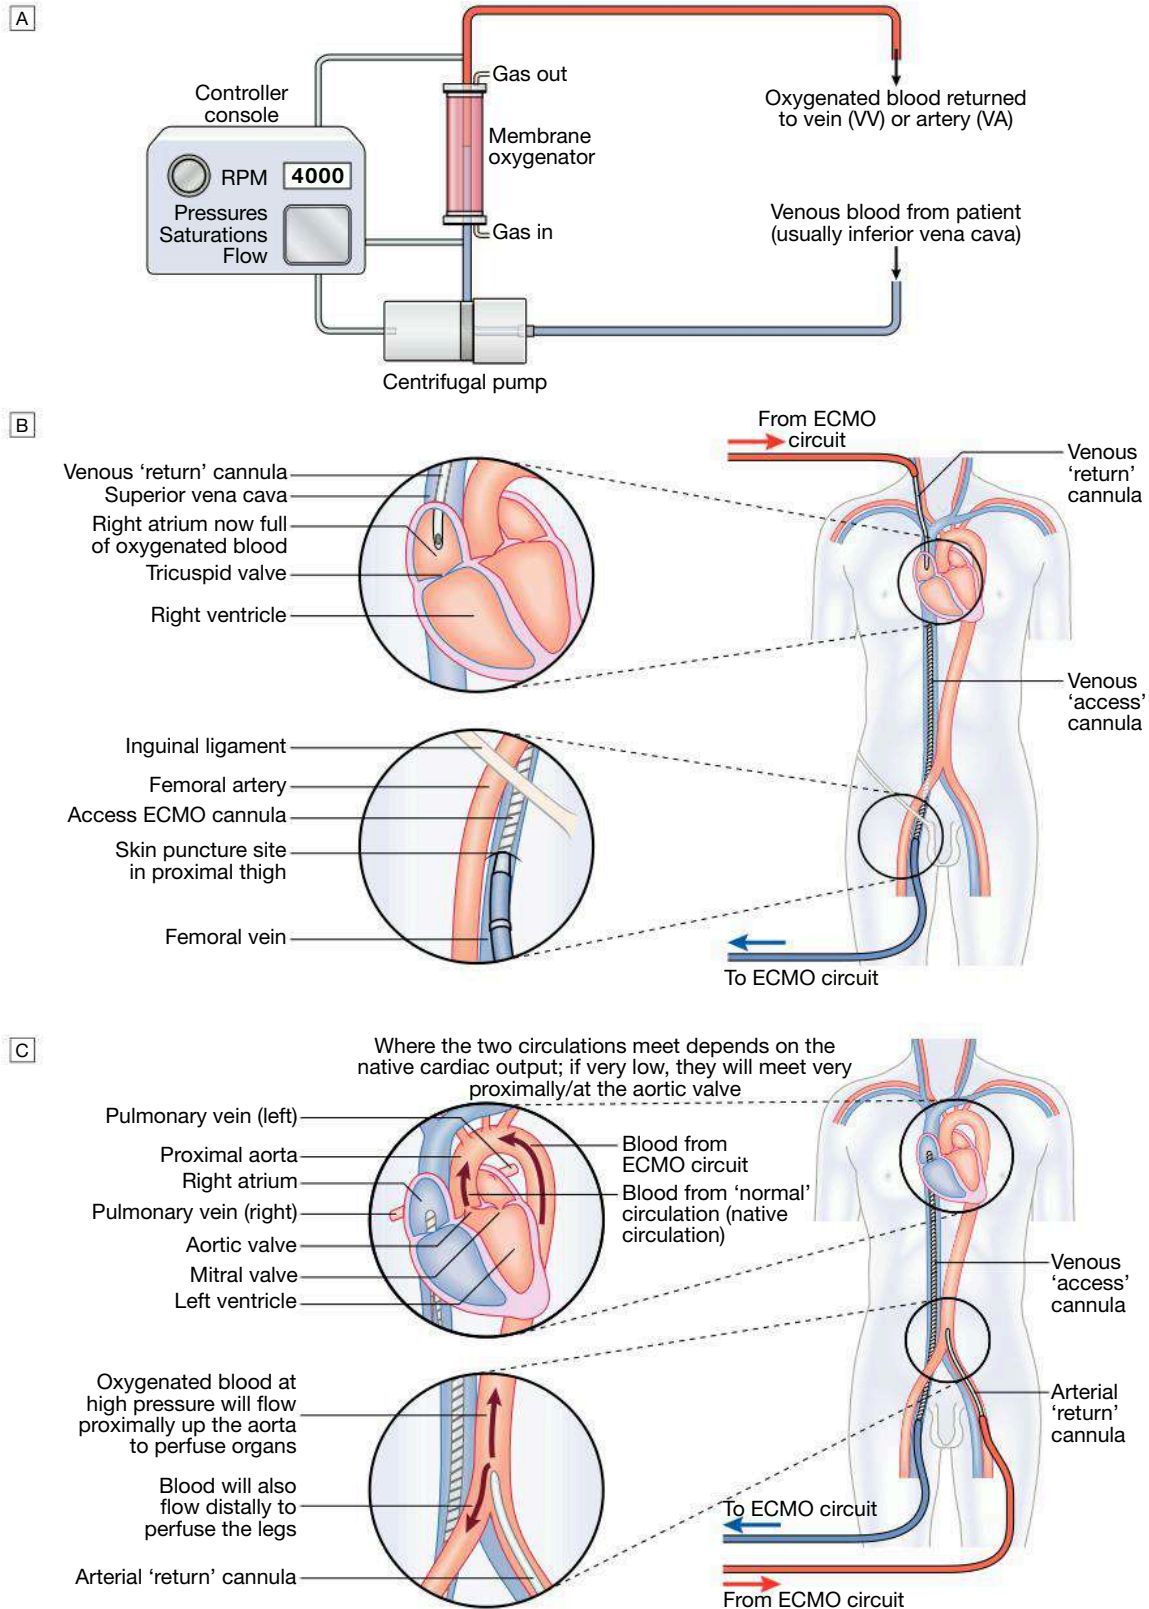

#### Venous–venous extracorporeal membrane oxygenation

In venous–venous extracorporeal membrane oxygenation (VV ECMO), large-bore central venous cannulae are inserted into the superior vena cava (SVC) and/or the inferior vena cava (IVC) via the femoral or jugular

veins, and advanced under ultrasound or fluoroscopic guidance (Fig. 9.24). Venous blood is then pumped through a membrane oxygenator. This device has thousands of tiny silicone tubes with air/oxygen gas on the other side of the tubes (the membrane). This facilitates the passage of oxygen into the blood and diffusion of carbon dioxide across the

membrane, where it is removed by a constant flow of gas (sweep gas). The oxygenated blood is then returned to the right atrium, from where it flows through the lungs as it would in the physiological state. This means that even if the lungs are contributing no oxygenation or carbon dioxide removal, a patient can remain well oxygenated and normocapnic.

**Fig. 9.24** Principles of extracorporeal membrane oxygenation (ECMO). **A** Basic ECMO circuit: venous-arterial (VA) and venous-venous (VV). **B** Example of a VV ECMO circuit. **C** Example of a VA ECMO circuit.

### Extracorporeal carbon dioxide removal

In some patients it is possible to maintain oxygenation but there is refractory hypercapnia. There are devices available that can remove carbon dioxide using a much lower blood flow rate than VV ECMO. Consequently, smaller venous cannulae, similar to those used in renal dialysis, can be sufficient to have a 'CO<sub>2</sub> dialysis' effect. This can be useful in patients in whom normocapnia is essential (such as those with a raised ICP), or those with refractory hypercapnia and adequate oxygenation. In addition, extracorporeal carbon dioxide removal can be used to reduce the required minute volume, which is a beneficial strategy for protecting the lungs against VILI or facilitating early extubation.

## Cardiovascular support

### Initial resuscitation

A brief assessment can usually yield enough information to determine whether a patient is at significant risk of an imminent cardiac arrest. If the patient is obtunded and there is no palpable radial or brachial pulse, then treatment should proceed as described on page 204.

In a peri-arrest situation, a single dose of intramuscular adrenaline (epinephrine) 0.5 mg (0.5 mL of 1:1000) can be life-saving. If expertise is available, a small dose of intravenous adrenaline (epinephrine) can delay cardiac arrest long enough to identify the cause of shock and institute other supportive measures; a suggested dose would be 50 µg (0.5 mL of 1:10000). If haemorrhage is considered a possibility, a 'major haemorrhage' alert should be activated, facilitating rapid access to large volumes of blood and blood products. A classification of shock is shown in [Box 9.45](#).

Venous access for the administration of drugs and fluids is vital but often difficult in critically unwell patients. Wide-bore cannulae are required for rapid fluid administration. In extremis, the external jugular vein can be cannulated; it is often prominent in low cardiac output states and readily visible on the lateral aspect of the neck. Occluding the vein distally with finger pressure makes it easier to cannulate, but care must be taken to remain high in the neck to avoid causing a pneumothorax. Intra-osseous or central venous access can be established if there are no visible peripheral veins. Ultrasound can provide assistance for rapid and safe venous cannulation. Rapid infusion devices are widely available and should be used for the delivery of warmed, air-free fluid and blood products.

9.45 Categories of shock	
Category	Description
<b>Hypovolaemic</b>	Can be haemorrhagic or non-haemorrhagic in conditions such as hyperglycaemic hyperosmolar state (p. 723) and burns
<b>Cardiogenic</b>	See page 202
<b>Obstructive</b>	Obstruction to blood flow around the circulation, e.g. major pulmonary embolism, cardiac tamponade, tension pneumothorax
<b>Septic</b>	See page 198
<b>Anaphylactic</b>	Inappropriate vasodilatation triggered by an allergen (e.g. bee sting), often associated with endothelial disruption and capillary leak (p. 183)
<b>Neurogenic</b>	Caused by major brain or spinal injury, which disrupts brainstem and neurogenic vasomotor control. High cervical cord trauma may result in disruption of the sympathetic outflow tracts, leading to inappropriate bradycardia and hypotension. Guillain-Barré syndrome (p. 1192) can involve the autonomic nervous system, resulting in periods of severe hypotension or hypertension
<b>Others</b>	e.g. Drug-related such as calcium channel blocker overdose; Addisonian crisis

### Fluid and vasopressor use

Resuscitation of the shocked patient should usually include a 10 mL/kg fluid challenge. Using colloid or crystalloid is acceptable; starch solutions are associated with additional renal dysfunction and should be avoided. The fluid challenge can be repeated if shock persists, to a maximum total of 30 mL/kg of fluid. However, commencing vasopressor therapy early in resuscitation is better than delaying until a large volume of fluid has been given. Amongst other beneficial effects, vasopressors induce vasoconstriction, reducing the capacitance of the circulation and effectively mobilising more fluid into the circulation.

If a patient remains shocked after 30 mL/kg of fluid has been administered, a re-evaluation of the likely cause is required, looking particularly for concealed haemorrhage or an obstructive pathology. A bedside echocardiogram is especially useful at this stage to evaluate cardiac output and exclude tamponade. Noradrenaline (norepinephrine) should be commenced as the first-line vasoactive agent in most cases, unless there is a strong indication to use a pure inotropic or chronotropic agent: for example, in cardiogenic shock or shock associated with bradycardia. If there is evidence of low cardiac output, adrenaline (epinephrine) or dobutamine should be commenced. Both agents are equally effective, but dobutamine causes more vasodilatation and additional noradrenaline may be required to maintain an adequate MAP. Vasopressin is added if hypotension persists despite high doses of noradrenaline and cardiac output is thought to be adequate.

In extreme situations it is acceptable to start infusions of inotropes through a well-sited, large-bore peripheral cannula, although central venous access and an arterial line (for monitoring) should be inserted as soon as possible. The actions of commonly used vasoactive drugs are summarised in [Box 9.46](#).

### Advanced haemodynamic monitoring

There are many different devices available to estimate cardiac output. Such devices employ a variety of mechanisms, including the Doppler effect of moving blood, changes in electrical impedance of the thorax, or the dilution of either an indicator substance or heat (thermodilution). The information is processed within the equipment, and often integrated with additional data, such as the arterial pressure waveform, to give an estimate of cardiac output and stroke volume.

When the aetiology of shock is straightforward and the patient is responding as predicted to treatment, the value of devices that estimate cardiac output is limited. Portable echocardiography has the advantage of giving qualitative information – for example, demonstrating aortic stenosis or a regional wall motion abnormality – as well as quantitative information on stroke volume, but it requires technical expertise.

Pulmonary artery (PA) catheters, sometimes referred to as Swan-Ganz catheters ([Fig. 9.25](#)), are invasive but provide useful information on pulmonary pressures, cardiac output, mixed venous oxygen saturations (see [Box 9.35](#)) and, by extrapolation, whether the cause of the shock is vasodilatation or pump failure. They can be helpful in complex cases, such as shock after cardiac surgery, or in patients with suspected

### 9.46 Actions of commonly used vasoactive agents

Drug	Action		
	Vasoconstrictor	Inotrope	Chronotrope
<b>Adrenaline (epinephrine)</b>	++	+++	++
<b>Noradrenaline (norepinephrine)</b>	++++	+	+
<b>Dobutamine</b>	–	++++	+++
<b>Vasopressin</b>	+++++	No action	– (reflex bradycardia)

**Fig. 9.25** A pulmonary artery (Swan-Ganz) catheter. **A** There is a small balloon at the tip of the catheter and pressure can be measured through the central lumen. The catheter is inserted via an internal jugular, subclavian or femoral vein and advanced through the right heart until the tip lies in the pulmonary artery. When the balloon is deflated, the pulmonary artery pressure can be recorded. **B** Advancing the catheter with the balloon inflated will 'wedge' the catheter in the pulmonary artery. Blood cannot then flow past the balloon, so the tip of the catheter will now record the pressure transmitted from the pulmonary veins and left atrium (known as the pulmonary artery capillary wedge pressure), which provides an indirect measure of the left atrial pressure. (LA = left atrium; LV = left ventricle; RA = right atrium; RV = right ventricle)

### 9.47 Interpreting haemodynamic data

Variable	Units	Reference range	Interpretation
Cardiac output (CO)	L/min	4–8 L/min	Low cardiac output suggests pump failure
Cardiac index (CI) Cardiac output referenced to the size of the patient	L/min/m <sup>2</sup>	2.5–4 L/min/m <sup>2</sup>	More useful than raw cardiac output alone, especially in smaller patients
Central venous pressure (CVP)	mmHg	0–6 mmHg	Reflects right atrial pressure – a non-specific measurement of right ventricular (RV) function and volume status Low levels suggest good RV function or hypovolaemia
Pulmonary artery systolic pressure (PA systolic)	mmHg	15–30 mmHg	Difficult to interpret in isolation Low levels suggest vasodilatation, hypovolaemia or right heart failure High levels are seen in many pathologies, e.g. left heart failure, primary pulmonary arterial hypertension (PAH), fluid overload
Pulmonary artery diastolic pressure (PA diastolic)	mmHg	5–15 mmHg	As with PA systolic pressure, difficult to interpret in isolation
Pulmonary artery capillary wedge pressure (PACWP)	mmHg	2–10 mmHg (should be within a few mmHg of PA diastolic)	Reasonable indication of left atrial pressure – raised in left heart failure and fluid overload Measurement is associated with injury to PA so should only be taken occasionally
Transpulmonary gradient (PA diastolic – PACWP)	mmHg	1–5 mmHg	A high gradient suggests the pathology is in the pulmonary arteries, e.g. primary PAH

pulmonary hypertension (Box 9.47). However, PA catheters are associated with some rare but serious complications, including lung infarction, PA rupture and thrombosis of the catheter itself. Such complications occur infrequently in centres that use PA catheters regularly; it should be stressed that a lack of familiarity within the wider clinical team is a relative contraindication to their use.

### Mechanical cardiovascular support

When shock is so severe that it is not possible to maintain sufficient organ perfusion with fluids and inotropic support, it is sometimes necessary to use an internal device to augment or replace the inadequate native cardiac output.

#### Intra-aortic balloon pump

An intra-aortic balloon counter-pulsation device is a long tube that is usually inserted into the femoral artery and fed proximally into the thoracic aorta. The basic principle is that a helium-filled balloon is able to inflate and deflate rapidly in time with the cardiac cycle. It is inflated in diastole,

thus augmenting forward flow of blood to the abdominal organs and improving diastolic pressure proximal to the balloon, thereby optimising coronary perfusion. While the principle is appealing, and an intra-aortic balloon pump (IABP) is often effective in achieving predetermined physiological goals, this does not translate into improved survival in cardiogenic shock. There are risks associated with thrombosis formation on the balloon, mesenteric ischaemia and femoral artery pseudo-aneurysm following removal of the device.

#### Venous–arterial extracorporeal membrane oxygenation

Venous–arterial extracorporeal membrane oxygenation (VA ECMO) can be life-saving in profound cardiogenic shock and has even been used effectively in refractory cardiac arrest. The circuit and principles are very similar to those described in 'VV ECMO' above (see Fig. 9.24) with one important difference: oxygenated blood is returned to the arterial system (rather than into the right atrium). This means that the pump needs to generate sufficient pressure to allow blood to flow through the systemic circulation. The sites of venous and arterial access can be either central (via a thoracotomy or sternotomy)

or peripheral via cannulae in the IVC/SVC and the femoral/subclavian artery. If the return cannula is peripherally sited (e.g. in the femoral artery), blood will flow back up the aorta from distal to proximal and perfuse the organs.

The outcome depends on the avoidance of complications (primarily, bleeding at the cannula site, intracranial haematoma, air embolism, infection and thrombosis) and improvement of the underlying condition. Most causes of profound cardiogenic shock are unlikely to resolve, and the potential availability of a longer-term solution, such as cardiac transplantation or insertion of a ventricular assist device, is a prerequisite for commencing VA ECMO in most centres.

## Renal support

Renal replacement therapy (RRT) is explained in detail on page 593. The key points relating to RRT in an intensive care context are:

- Haemodynamic instability is common. Continuous therapies are widely believed to cause less haemodynamic instability than intermittent dialysis. However, many units use intermittent dialysis without significant problems.
- Haemodialysis and haemofiltration are equally good. Although there are theoretical benefits to removing inflammatory cytokines with haemofiltration, this does not translate into improved survival.
- Anticoagulation is usually achieved using citrate or heparin. Citrate has a better profile for anticoagulating the extracorporeal circuit without inducing an increased bleeding risk, but may accumulate in patients with profound multi-organ failure.
- Most patients who survive intensive care will regain adequate renal function to live without long-term renal support.
- A thorough investigation for reversible causes of renal dysfunction should always be undertaken in conjunction with instigation of renal support (see Fig. 18.18).
- Shock appears to reverse more rapidly when renal support is instituted. Commencing renal support soon after a patient develops renal 'injury' (when serum creatinine is more than two times higher than baseline) is probably beneficial in the context of septic shock.

## Neurological support

A diverse range of neurological conditions require management in intensive care. These include the various causes of coma, spinal cord injury, peripheral neuromuscular disease and prolonged seizures.

The goals of care in such cases are to:

- Protect the airway, if necessary by endotracheal intubation.
- Provide respiratory support to correct hypoxaemia and hypercapnia.
- Treat circulatory problems, e.g. neurogenic pulmonary oedema in subarachnoid haemorrhage, autonomic disturbances in Guillain-Barré syndrome, and spinal shock following high spinal cord injuries.
- Manage acute brain injury with control of ICP.
- Manage status epilepticus using antiepileptic agents such as levetiracetam, phenytoin and benzodiazepines. In refractory cases an infusion of sodium thiopental or ketamine may be required.

The aim of management in acute brain injury is to optimise cerebral oxygen delivery by maintaining normal arterial oxygen content and a cerebral perfusion pressure (CPP) of > 60mmHg. Secondary insults to the brain, such as hypoxaemia, hyper/hypoglycaemia and prolonged seizures, must be avoided. ICP rises in acute brain injury as a result of haematoma, contusions, oedema or ischaemic swelling. Raised ICP causes damage to the brain in two ways: direct damage to the brainstem and motor tracts as a result of downward pressure and herniation through the tentorium cerebelli and foramen magnum, and indirect damage by reducing CPP. Cerebral blood flow is dependent on an adequate CPP. The CPP is determined by the formula:

$$\text{CPP} = \text{MAP} - \text{ICP}$$

ICP can be measured by pressure transducers that are inserted directly into the brain tissue. The normal upper limit for ICP is 15mmHg and an upper acceptable limit of 20mmHg is usually adopted in intensive care. Sustained pressures of > 30mmHg are associated with a poor prognosis. Various strategies are used to control ICP: maintaining normocapnia, preventing any impedance to venous drainage from the head, giving osmotic agents such as mannitol and hypertonic saline, and using hypothermia and decompressive craniectomy. No single technique has been shown to improve outcome in severe intracranial hypertension.

CPP should be maintained above 60mmHg by ensuring adequate fluid replacement and, if necessary, by treating hypotension with a vasopressor such as noradrenaline (norepinephrine). Complex neurological monitoring must be combined with frequent clinical assessment of GCS, pupillary response to light and focal neurological signs.

## Daily clinical management in intensive care

### Clinical review

In intensive care, detailed clinical examination should be performed daily to identify changes to a patient's condition and review the latest diagnostic information. Further focused clinical reviews are usually incorporated into twice-daily ward rounds. Each ward round offers an ideal opportunity to monitor and document adherence with relevant care bundles. A care bundle is a group of interventions that, when implemented concurrently, have provided evidence of clinical benefit. The mnemonic 'FAST HUG' provides a useful checklist of interventions that reduce intensive care complications: *feeding/fluids, analgesia, sedation, thromboprophylaxis, head of bed elevation* (to reduce the incidence of passive aspiration), *ulcer prophylaxis* and *glucose control*.

Other key aspects of the daily review are outlined on page 176. The over-arching aim of the review is to identify the issues that are impeding recovery from critical illness, and make alterations to address them. In addition, specific and realistic goals for each relevant organ system should be defined, facilitating the autonomous titration of therapy by the bedside critical care nurse. An example of daily goals may be: 'Titrate the noradrenaline (norepinephrine) to achieve a MAP of 65mmHg, aim for a negative fluid balance, titrate  $FIO_2$  to achieve oxygen saturations of 92%–95% and titrate sedation to a RASS score of 0 to -1' (see Box 9.49).

### Infection surveillance

Infection surveillance is an important part of the daily review as nosocomial infection is common in critically ill patients. Trends in temperature, heart/respiratory rate and secretion load can all be early indicators of ventilator-associated pneumonia (VAP). Likewise leucocytosis and a raised C-reactive protein are measured frequently, but are not specific enough to guide therapy alone. Procalcitonin (PCT) is increasingly used to give more specific information on bacterial infection. A rapidly reducing trend can allow for a shortening of antibiotic courses (reducing the likelihood of generating resistant organisms) and a persistently low PCT in a shocked patient can alert the clinician to the possibility of an aetiology other than sepsis. Severe viral and fungal infections, e.g. COVID-19, can cause an elevated PCT and occasionally sepsis can develop before the PCT has risen, so as with all investigations the result should be used as adjunct to clinical assessment.

### Sedation and analgesia

Most patients require some degree of sedation and analgesia to ensure comfort, relieve anxiety and tolerate mechanical ventilation. Some conditions, such as critically high ICP or critical hypoxaemia, require deep sedation to reduce tissue oxygen requirements and protect the brain from the peaks in ICP associated with coughing or gagging. For the

### 9.48 Properties of sedative and analgesic agents used in ICU

Drug	Mode of action	Advantages	Disadvantages
Propofol	Intravenous anaesthetic	Rapid onset and offset	Large cumulative doses can cause multi-organ failure, especially in children – the 'propofol infusion syndrome'
Alfentanil	Potent opiate analgesic	Rapid onset and offset	High doses may be required Agitation may persist
Morphine	Opioid	Analgesia	Active metabolites and accumulation cause slow offset
Midazolam	Benzodiazepine sedative	Can be used in children	Active metabolites and accumulation cause slow offset
Remifentanyl	Very potent opiate	Analgesia and tube tolerance	Respiratory depression – extreme caution in non-intubated patients
Dexmedetomidine	$\alpha_2$ -adrenergic agonist	Excellent tube tolerance Less delirium Can be used in awake patients	Cost and availability

majority of patients, however, optimal sedation is an awake and lucid patient who is comfortable and able to tolerate an endotracheal tube (termed 'tube tolerance').

Over-sedation is associated with longer ICU stays, a higher prevalence of delirium, prolonged requirement for mechanical ventilation, and an increased incidence of ICU-acquired infection. Box 9.48 compares the various agents used for sedation in intensive care. The key principles are that the patient should primarily receive analgesia, rather than anaesthesia, and caution should be used with drugs that accumulate in hepatic and renal dysfunction. Often a combination of drugs is used to achieve the optimal balance of sedation and analgesia.

Sedation is monitored via clinical sedation scales that record responses to voice and physical stimulation. The Richmond Agitation–Sedation Scale (RASS) is the best-recognised tool (see Box 9.49 for details). Regular use of a scoring system to adjust sedation is associated with a shorter ICU stay. Many ICUs also have a daily 'sedation break', when all sedation is stopped in appropriate cases for a short period. This is commonly combined with a trial of spontaneous breathing aiming to shorten the duration of mechanical ventilation.

### Delirium in intensive care

Delirium is discussed in Chapter 34. It is extremely common in critically ill patients and often becomes apparent as sedation is reduced. Hypoactive delirium is far more common than hyperactive delirium, but is easily missed unless routine screening is undertaken. A widely used bedside assessment is the CAM-ICU score. The patient is requested to squeeze the examiner's hand in response to instruction and questions, aiming to ascertain whether disordered thought or sensory inattention are present.

Delirium of any type is associated with poorer outcome. Management is focused on non-pharmacological interventions such as early mobilisation, reinstatement of day–night routine, noise reduction, cessation of drugs known to precipitate delirium, and treatment of potential underlying causes such as thiamine replacement in patients at risk of Wernicke's encephalopathy. Patients with agitated delirium that is refractory to verbal de-escalation should initially be managed with small doses of parenteral antipsychotics, changed to the enteral route once control is established. Atypical antipsychotics such as olanzapine and quetiapine can be more efficacious than traditional drugs such as haloperidol. Pharmacological interventions are not useful as prophylaxis or in hypoactive delirium. Additional information on diagnosis and management of delirium can be found on page 1304.

### Weaning from respiratory support

As the condition that necessitated ventilation resolves, respiratory support is gradually reduced: the process of 'weaning' from ventilation. Some approaches to weaning are described below.

### 9.49 Richmond Agitation–Sedation Scale (RASS)

Score	Term	Description
+4	Combative	Overtly combative, violent or immediate danger to staff
+3	Very agitated	Pulls on/removes tubes or catheters, or aggressive to staff
+2	Agitated	Frequent non-purposeful movement or patient–ventilator dyssynchrony
+1	Restless	Anxious or apprehensive but no aggressive or vigorous movements
0	Alert and calm	
–1	Drowsy	Not fully alert but sustained awakening (> 10 secs) with eye opening/contact to voice
–2	Light sedation	Brief awakening (< 10 secs) with eye contact to voice
–3	Moderate sedation	Movement but no eye contact to voice
–4	Deep sedation	Movement to physical stimulation but no response to voice
–5	Unrousable	No response to voice or physical stimulation

### Spontaneous breathing trials

A spontaneous breathing trial involves the removal of all respiratory support followed by close observation of how long the patient is able to breathe unassisted. The technique is particularly effective when linked to a reduction in sedation. PEEP and pressure support are reduced to low levels, or patients are disconnected from the ventilator and breathe the oxygen or humidified air through the endotracheal tube. Signs of failure include rapid shallow breathing, hypoxaemia, rising  $PaCO_2$ , sweating and agitation. Patients who pass a spontaneous breathing trial are assessed for suitability of extubation (endotracheal tube removal).

### Progressive reduction in pressure support ventilation

Progressive reduction in pressure support ventilation (PSV) is applied to each breath over a period of hours or days, according to patient response. Some ICU ventilators have software that allows the facility to wean the support provided automatically.

A useful tool to guide the weaning process is the rapid shallow breathing index (RSBI). This composite score of a patient's spontaneous

respiratory rate and tidal volume (respiratory rate divided by tidal volume in litres) gives a numerical indication of how difficult the patient is finding breathing at that particular level of support. A RSBI value of > 100 suggests that a patient is working at a level that would be unsustainable for longer periods.

## Extubation

It is not possible to predict whether a patient is ready to be extubated accurately; the timing relies heavily on clinical judgement. There are, however, some principles that can aid decision-making. Patients must have stable ABGs with resolution of hypoxaemia and hypercapnia despite minimal ventilator pressure support and a low  $FIO_2$ . Conscious level must be adequate to protect the airway, comply with physiotherapy and cough. Furthermore, an assessment must be made as to whether the patient can sustain the required minute volume without ventilator support. This depends on the condition of patients' lungs, their strength and other factors affecting the  $PaCO_2$ , such as temperature and metabolic rate. Frequently it is not possible to meet all of these criteria and the decision to extubate relies on a balance of risks and benefits. The need for re-intubation following extubation is associated with poorer outcome, but patients who are not given the opportunity to breathe without a ventilator will also be at increased risk of ventilator-associated complications such as pneumonia and myopathy.

## Tracheostomy

A tracheostomy is a percutaneous tube passed into the trachea (usually between the first and second, or second and third tracheal rings) to facilitate longer-term ventilation. The advantages and disadvantages of tracheostomy insertion are listed in [Box 9.50](#). When ventilation weaning has been unsuccessful, a tracheostomy provides a bridge between intubation and extubation; the patient can have increasing periods free of ventilator support but easily have support reinstated. A tracheostomy can be inserted percutaneously, using a bronchoscope in the trachea for guidance, or surgically under direct vision. Occasionally, a patient will have a tracheostomy in situ following a laryngectomy. Such patients are important to identify, as emergency management in the event of a tracheostomy problem (blockage or displacement) must be through the tracheostomy site; access will not be possible via the upper airway.

## Nutrition

It is crucial that critically ill patients receive adequate calories, protein and essential vitamins and minerals. Calculation of exact requirements is complex and requires the expertise of a dietitian. It is, however, useful to make a rough estimation of requirements (see [Ch. 22](#)). Under-feeding leads to muscle wasting and delayed recovery, while over-feeding can lead to

### 9.50 Advantages and disadvantages of tracheostomy

#### Advantages

- Patient comfort
- Improved oral hygiene
- Access for tracheal toilet
- Ability to speak with cuff deflated and a speaking valve attached
- Reduced equipment 'dead space' (the volume of tubing)
- Earlier weaning and ICU discharge
- Reduced sedation requirement
- Reduced vocal cord damage

#### Disadvantages

- Immediate complications: hypoxaemia, haemorrhage
- Tracheostomy site infection
- Tracheal damage; late stenosis

biliary stasis, jaundice and steatosis. Enteral feeding is preferred where possible because it avoids the infective complications of total parenteral nutrition (TPN) and helps to maintain gut integrity. However, TPN is recommended for patients who are likely to have a sustained period without effective enteral feeding, or who are already malnourished. Caution must be taken to avoid the consequences of refeeding syndrome (p. 768).

## Other essential components of intensive care

Survival after critical illness depends, to a large extent, on the prevention of medical complications during recovery from the primary insult.

### Thromboprophylaxis

DVT, venous catheter-related thrombosis and PE are common in critically ill patients. Low-molecular-weight heparin (LMWH) should be administered to all patients, unless there is a contraindication. Often patients at highest risk of thrombosis, such as those with hepatic dysfunction or those who have suffered major trauma, have a relative contraindication to heparin. Such cases mandate daily evaluation of the risk-benefit ratio, and LMWH should be administered as soon as it is deemed safe to do so. Mechanical thromboprophylaxis, such as intermittent calf compression devices, are useful adjuvants in high-risk patients.

### Glucose control

Hyperglycaemia is harmful in critical illness and may occur in people with pre-existing diabetes or undiagnosed diabetes, following administration of high-dose glucocorticoids, or as a consequence of 'stress hyperglycaemia'. Hyperglycaemia is commonly managed by infusion of intravenous insulin titrated against a 'sliding scale'. Intensive management of hyperglycaemia with insulin can result in hypoglycaemia, which may also be harmful in critical illness. Therefore, a compromise is to titrate insulin to a blood glucose level of 6–10 mmol/L (108–180 mg/dL).

### Blood transfusion

Many critically ill patients become anaemic due to reduced red cell production and red cell loss through bleeding and blood sampling. However, red cell transfusion carries inherent risks of immunosuppression, fluid overload, organ dysfunction from microemboli and transfusion reactions. In stable patients, a haemoglobin level of 70 g/L is a safe compromise between optimisation of oxygen delivery and the risks of transfusion. This transfusion threshold should be adjusted upwards for situations where oxygen delivery is critical, such as in patients with active myocardial ischaemia.

### Peptic ulcer prophylaxis

Stress ulceration during critical illness is a serious complication. Proton pump inhibitors or histamine-2 receptor antagonists are effective at reducing the incidence of ulceration. There is, however, a suggestion that the use of these agents, particularly in conjunction with antibiotics, may increase the incidence of nosocomial infection, especially with *Clostridoides difficile* (p. 311). It is therefore common practice to stop ulcer prophylaxis once consistent absorption of enteral feed is established.

## Complications and outcomes of critical illness

The majority of patients will survive their episode of critical illness. While some will return to full, active lives, there are many who have ongoing physical, emotional and psychological problems.

## Adverse neurological outcomes

### Brain injury

Head injury, hypoxic–ischaemic injury and infective, inflammatory and vascular pathologies can all irreversibly injure the brain. If treatment is unsuccessful, patients will either die or be left with a degree of disability. In the latter situation, the provision of ongoing organ support will depend on the severity of the injury, the prognosis, and the wishes of the patient (usually expressed via relatives). Brain death is a state in which cortical and brainstem function is irreversibly lost. Diagnostic criteria for brain death vary between countries (Box 9.51); if satisfied, these criteria allow physicians to withdraw active treatment and discuss the potential for organ donation. Diagnosing brain death is complex and should be done only by physicians with appropriate expertise, as clinical differentiation from reduced consciousness can be challenging (Box 9.52). Where there is doubt – for example, in patients with coexisting spinal injury or localised brainstem pathology – additional investigations should be performed, such as a brain perfusion scan.

The ‘locked-in’ syndrome occurs when a patient is paralysed but has preserved hemispheric function. This is usually caused by a lesion in the pons and is frequently of vascular origin. Communication can usually be maintained via vertical eye movements or blinking if these functions are preserved. The term ‘vegetative state’ implies some retention of brainstem function and minimal cortical function, with loss of awareness of the environment. In contrast, ‘minimally conscious state’ implies that there is some degree of awareness and intact brainstem function. Confident distinction between these states is important and requires careful assessment, often over a period of time. Brain death is, by definition, irreversible but other states may offer hope for improvement.

### ICU-acquired weakness

Weakness is common among survivors of critical illness. It is usually symmetrical, proximal and most marked in the lower limbs. Critical illness polyneuropathy and myopathy can occur simultaneously and, within the constraints of an altered sensorium, it can be impossible to distinguish the two conditions clinically. Risk factors for both processes include the severity of multi-organ failure, poor glycaemic control and the use of muscle relaxants and glucocorticoids.

#### Critical illness polyneuropathy

This is due to peripheral nerve axonal loss and characteristically presents as proximal muscle weakness with preserved sensation. It may also manifest as failure to wean from the ventilator secondary to respiratory muscle weakness. Electrophysiological studies of the affected nerves can be helpful, especially to rule out other potential causes such as Guillain–Barré syndrome. Conduction studies typically show reduced amplitude of transmitted voltage action potential with preserved velocity (compare with findings in Guillain–Barré syndrome; pp. 1133 and 1192). There are no specific treatments aside from resolution of the underlying cause and rehabilitation. Weakness may persist long into the convalescence stage of illness. In some cases, the clinical picture may be more in keeping with individual nerve involvement. This may be due to local pressure effects or part of a generalised picture. Great care must be taken to avoid pressure on high-risk areas such as the neck of the fibula where the common peroneal nerve navigates a superficial course. Nerve palsies such as foot drop can be permanent.

#### Critical illness myopathy

Although loss of muscle bulk is related to immobility and the catabolic state of critical illness, it is likely that microvascular and intracellular pathophysiological processes are also involved in critical illness myopathy. These processes result in loss of actin myofibrils and muscle weakness. Typically, the CK is normal or only mildly elevated. Like critical illness polyneuropathy, critical illness myopathy is usually a clinical diagnosis.

### 9.51 UK criteria for the diagnosis of brain death

#### Preconditions for considering a diagnosis of brain death

- The patient is deeply comatose:
  - a. There must be no suspicion that coma is due to depressant drugs, such as narcotics, hypnotics, tranquillisers
  - b. Hypothermia has been excluded – rectal temperature must exceed 35°C
  - c. There is no profound abnormality of serum electrolytes, acid–base balance or blood glucose concentrations, and any metabolic or endocrine cause of coma has been excluded
- The patient is maintained on a ventilator because spontaneous respiration has been inadequate or has ceased. Drugs, including neuromuscular blocking agents, must have been excluded as a cause of the respiratory failure
- The diagnosis of the disorder leading to brain death has been firmly established. There must be no doubt that the patient is suffering from irremediable structural brain damage

#### Tests for confirming brain death

- All brainstem reflexes are absent:
  - a. The pupils are fixed and unreactive to light
  - b. The corneal reflexes are absent
  - c. The vestibulo-ocular reflexes are absent – there is no eye movement following the injection of 20 mL of ice-cold water into each external auditory meatus in turn
  - d. There are no motor responses to adequate stimulation within the cranial nerve distribution
  - e. There is no gag reflex and no reflex response to a suction catheter in the trachea
- No respiratory movement occurs when the patient is disconnected from the ventilator for long enough to allow the carbon dioxide tension to rise above the threshold for stimulating respiration ( $P_{aCO_2}$  must reach 6.7 kPa/50 mmHg)

The diagnosis of brain death should be made by two doctors of a specified status and experience. The tests are usually repeated after a short interval to allow blood gases to normalise before brain death is finally confirmed.

Nerve conduction studies and electromyography may be suggestive of critical illness myopathy, and helpful in ruling out other pathology. A muscle biopsy is required to confirm the diagnosis (p. 1133), although it is seldom used in clinical practice as there are no specific treatment options. Biopsies typically show selective loss of the thick myofibrils and muscle necrosis. Management is conservative and the prognosis is good in ICU survivors.

### Airway complications

Prolonged instrumentation of the airway is occasionally associated with injuries that may have long-term consequences. Vocal cord oedema is common after intubation, especially in female patients. This may require urgent re-intubation, a short course of systemic steroids or the insertion of a tracheostomy to allow oedema to settle. Long-term vocal cord problems occur in a small number of ICU survivors. This may include vocal cord palsies or chronically increased vocal cord tone causing either a weak voice or stridor.

Both tracheal intubation and tracheostomy can cause damage to the trachea (either at the insertion point or from ischaemia at the level of the cuff). This may be associated with tracheal stenosis or a tracheoesophageal fistula. If any of these complications is suspected, referral to a throat specialist is recommended.

### Micro- and macrovascular complications

Areas of tissue ischaemia can occur during an episode of critical illness. Causative mechanisms may include: micro-emboli; reduced tissue perfusion from vasoconstriction or poor cardiac output; pressure from positioning or medical devices such as those securing a tracheostomy; invasive arterial lines causing arterial thrombosis. Vascular surgical opinion may be helpful in recommending specific treatments or management of necrotic tissue. Wherever possible, steps should be taken to reduce

9.52 Classification of brain death and reduced conscious states			
Diagnosis	Features	Investigation	Prognosis
<b>Brain death</b>	See Box 9.51	Often not required if cranial imaging shows compatible cause and patient meets clinical criteria In diagnostic doubt: four-vessel angiogram (fluoroscopic or CT) of cerebral vessels or isotope scan of brain to demonstrate absence of cerebral blood flow	Time of confirmed brain death is recorded as time of death Potential to donate organs – donation after brain death (DBD) donor
<b>Vegetative state (VS)</b> <b>'Persistent VS' &gt; 1 month</b> <b>'Permanent VS' &gt; 1 year</b>	No reaction to verbal stimuli Some reaction to noxious stimuli Sleep–wake cycles (periods of eye opening) Maintained respiratory drive Intact brainstem reflexes Occasional automatic movements (yawning, swallowing)	Cranial imaging for primary cause Maintained cortical blood flow	Poor. May be better with traumatic aetiology
<b>Minimally conscious state</b>	Some reaction to verbal stimuli Some reaction to noxious stimuli Spontaneous movements Intact brainstem reflexes	EEG demonstrates reactivity	Variable. Recovery of function more likely than in VS
<b>Locked-in syndrome</b>	Cortex is intact but bilateral motor tracts are damaged Can be partial or complete, i.e. some response to verbal stimuli (e.g. vertical eye movements to communicate) Variable brainstem reflexes No limb movement to noxious stimuli	Imaging for primary cause – commonly MRI or CT will show brainstem or pontine infarction	Variable and depends on cause – progress can continue over months to years

the incidence of these complications, e.g. active pressure management. However, in critically unwell patients, peripheral ischaemia can occur despite optimal management.

### Other complications

Cardiopulmonary resuscitation can frequently lead to damage to the integrity of the chest wall. This appears to be more common with the use of automated compression devices although it is possible this reflects increased survivorship in this cohort. Anterior rib fractures and sternocostal dislocation are seen most commonly and this pattern of injury can lead to a flail segment of the chest wall, or a flail sternum. The segment moves independently from the rest of the chest; this is a problem when ventilation is spontaneous as the negative pressure draws the flail segment inwards. Simple rib fractures can usually be managed with analgesia but flail segments frequently benefit from surgical fixation (Fig. 9.26). The experience of critical illness and the necessary invasive management can leave patients with profound psychological sequelae akin to the post-traumatic stress syndrome seen in many survivors of conflict. Specialist psychological help is required in managing these issues. Sometimes recovering patients benefit from returning to the ICU to see the environment in a different way and gain a better understanding of the processes and procedures that haunt them.

Long-term physical consequences are also common. Many diseases are not completely cured, but follow a relapsing–remitting course; patients who have been critically ill with sepsis are far more likely than others in the general population to suffer from it again. Intensive care follow-up clinics provide an excellent forum for addressing such issues, and for coordinating care involving a variety of medical specialties.

### The older patient

Critically ill older patients present additional challenges following intensive care discharge (Box 9.53). As the ability to make a full recovery depends on frailty rather than chronological age, it can be helpful to use a validated frailty scoring system (p. 1300) to inform admission decision-making.

Rehabilitation medicine has much to offer survivors of critical illness, and an early referral is beneficial when it is clear that a patient is likely to survive with significant morbidity.

### Withdrawal of active treatment and death in intensive care

#### Futility

The idea of futility is not new: Hippocrates stated that physicians should 'refuse to treat those who are overmastered by their disease, realising that in such cases medicine is powerless'. In intensive care, where the concept of futility is often used as a criterion to limit or withdraw life-sustaining treatment, it is helpful to have a working definition on which families and physicians can agree. It is, therefore, reasonable to define futility in such circumstances as the point at which recovery to a quality of life that the patient would find acceptable has passed. The primary insult may be neurological (irreversible brain injury not meeting criteria for brain death), or multi-organ failure that is refractory to treatment.

#### Death

While most patients prefer to die at home, many spend their final days in hospital. Chapter 8 details the medical, legal and ethical priorities that should guide patient management once the decision to withdraw active treatment has been made. The decision to shift the focus of care to palliation should not change its intensity; it is the over-arching objective that changes. Only interventions that will improve the quality of a patient's remaining life should be offered. In the ICU, it is often appropriate to continue infusions of sedatives and analgesics, as reducing or stopping them may cause unnecessary pain and agitation. Measures that were instituted to prolong life should be withdrawn (usually including cessation of inotropes and extubation) to allow the patient to die peacefully with their family and friends present.

**Fig. 9.26** Anterior chest wall injuries are common after CPR. **A** Here is shown a flail sternum with multiple bilateral chest wall fractures. The patient underwent rib fixation following unsuccessful attempts at weaning. **B** The post-fixation chest radiograph is shown and weaning was successful shortly afterwards. *Images courtesy of Dr Jonathan Serhan.*

### 9.53 The critically ill older patient

- **ICU demography:** increasing numbers of critically ill older patients are admitted to the ICU; more than 50% of patients in many general ICUs are over 65 years old.
- **Outcome:** affected to some extent by age, as reflected in APACHE II (see Box 9.55), but age should not be used as the sole criterion for withholding or withdrawing ICU support.
- **Cardiopulmonary resuscitation (CPR):** successful hospital discharge following in-hospital CPR is rare in patients over 70 years old in the presence of significant chronic disease.
- **Functional independence:** tends to be lost during an ICU stay and prolonged rehabilitation may subsequently be necessary.
- **Specific problems:**
  - Skin fragility and ulceration
  - Poor muscle strength: difficulty weaning from ventilator and mobilising
  - Delirium: compounded by sedatives and analgesics
  - High prevalence of underlying nutritional deficiency

## Organ donation

### Donation after brain death

The diagnosis of brain death is discussed on page 215. Once brain death has been confirmed, consideration should be given to organ donation, termed 'donation after brain death' (DBD). Time of death is recorded as the time when the first series of brain death tests are undertaken, although the deceased patient continues to be ventilated. The practice of organ donation varies throughout the world but the principles remain the same.

Organ donation specialists are contacted and they begin the process of establishing the suitability of any organs for transplantation and matching potential recipients. Many patients will have expressed their wishes through an organ donor registration scheme but agreement of family and next of kin is a moral (and sometimes legal) prerequisite. Once the organ retrieval theatre team have been assembled and all preliminary tests have been completed, the deceased patient is transferred to the operating theatre and the organs are sequentially removed.

### Donation after cardiac death

If a patient does not meet brain death criteria but withdrawal of treatment has been agreed, donation of organs with residual function may

be appropriate. This is termed 'donation after cardiac death' (DCD). If the patient dies within a short period following the commencement of 'warm ischaemic time' (the time to asystole following the onset of physiological derangement after the withdrawal of active treatment), then DCD can proceed. The deceased patient is transferred to an operating theatre and the agreed organs (lungs, liver, kidney and pancreas and occasionally heart) are retrieved. As heart valves and corneas can be retrieved later (within a longer time frame), tissue retrieval may occur in the mortuary.

## Post-mortem examination or autopsy

There are several indications to request a post-mortem examination. A coroner (or legal equivalent) may initiate the process if a death is unexpected or violent, or has occurred under suspicious circumstances. The treating physician(s) may request one if they are unable to establish a cause of death or there is agreement that it may yield information of interest to the family or clinical team. The post-mortem diagnosis is occasionally at odds with the ante-mortem diagnosis and it is a very useful learning exercise to review the results with all those involved in the patient's care.

## Discharge from intensive care

Discharge is appropriate when the original indication for admission has resolved and the patient has sufficient physiological reserve to continue to recover without the facilities of intensive care. Many ICUs and HDUs function as combined units, allowing 'step-down' of patients to HDU care without changing the clinical team involved. Discharge from ICU is stressful for patients and families, and clear communication with the clinical team accepting responsibility is vital. Nursing ratios change from 1:1 (one nurse per patient) or 1:2 to much lower staffing levels. Discharges from ICU or HDU to standard wards should take place within normal working hours to ensure adequate medical and nursing support and detailed handover. Discharge outside normal working hours is associated with higher ICU re-admission rates and increased mortality. The receiving team should be provided with a written summary, including the information listed in Box 9.54. The ICU team should remain available for advice; many ICU teams provide an outreach service to supply advice and facilitate continuity of care.

### 9.54 How to write an ICU discharge summary: information to be included

- Summary of diagnosis and progress in intensive care
- Current medications and changes to regular medications with justifications
- Antibiotic regimen and suggested review dates
- Results of positive microbiological tests
- Positions of invasive devices and insertion dates
- Escalation plan in the event of deterioration
- Pending investigations and specialty consultations
- If the physiology remains abnormal due to chronic disease, rapid response triggers should be adjusted accordingly

## Critical care scoring systems

Admission and discharge criteria vary between ICUs, so it is important to define the characteristics of the patients admitted in order to assess the effects of the care provided on the outcomes achieved. Two systems are widely used to measure severity of illness (see [Box 9.55](#) for further details):

- *APACHE II*: Acute Physiology Assessment and Chronic Health Evaluation
- *SOFA score*: Sequential Organ Failure Assessment tool.

When combined with the admission diagnosis, scoring systems have been shown to correlate well with the risk of death in hospital. Such outcome predictions are useful at a population level but lack the specificity to be of use in decision-making for individual patients.

### 9.55 Comparison of APACHE II and SOFA scores

#### APACHE II score

- An assessment of admission characteristics (e.g. age and pre-existing organ dysfunction) and the maximum/minimum values of 12 routine physiological measurements during the first 24 hours of admission (e.g. temperature, blood pressure, GCS) that reflect the physiological impact of the illness
- Composite score out of 71
- Higher scores are given to patients with more serious underlying diagnoses, medical history or physiological instability; higher mortality correlates with higher scores

#### SOFA score

- A score of 1–4 is allocated to six organ systems (respiratory, cardiovascular, liver, renal, coagulation and neurological) to represent the degree of organ dysfunction, e.g. platelet count  $> 150 \times 10^9/L$  scores 1 point,  $< 25 \times 10^9/L$  scores 4 points
- Composite score out of 24
- Higher scores are associated with increased mortality

## Multiple Choice Questions

9.1. Regarding monitoring in the critical care area, which one of the following statements is true?

- A. The three-lead ECG does not accurately reflect the ventricular rate
- B. Oxygen saturation readings are inaccurate in severe jaundice
- C. End-tidal carbon dioxide (ETCO<sub>2</sub>) is a reliable reflection of arterial CO<sub>2</sub> in critically ill patients
- D. The central venous pressure gives an estimate of left atrial pressure
- E. The pulse oximetry trace can suggest if peripheral perfusion is poor

Answer: E.

When perfusion is poor the saturation plethysmograph can become flat as the pulsatile element of the blood plethysmography is lost. Modern SpO<sub>2</sub> monitors can compensate for a degree of reduction in perfusion and are not affected by jaundice. The ECG trace reflects ventricular rate. ETCO<sub>2</sub> becomes less reflective of arterial CO<sub>2</sub> – as the efficiency of the lungs decreases the larger the discrepancy. Central venous pressure gives an estimation of right atrial pressure.

9.2. There are several proposed physiological mechanisms that cause hypoxaemia. Which of these disease–mechanism pairings is correct?

- A. Pulmonary embolism – shunt
- B. Opiate overdose – shunt
- C. Pulmonary oedema – V/Q mismatch
- D. Chronic obstructive pulmonary disease – V/Q mismatch
- E. Lobar pneumonia – central hypoventilation

Answer: D.

COPD causes areas of hypoventilated lung; however, these areas may still have reasonable perfusion, i.e. V/Q mismatch. Pulmonary embolism likewise causes V/Q mismatch as unaffected lung units get relatively over-perfused. Opiate overdose causes central hypoventilation and lobar pneumonia typically causes shunt.

9.3. A 50-year-old man sustains a cardiac arrest while out jogging. He is resuscitated by paramedics at the scene but has sustained a severe brain injury. Four months after the event he is examined and found to have normal brainstem reflexes. He coughs spontaneously and swallows secretions, however, makes no sound other than occasional grunts. He has jerky eye movements and appears to follow people within the room but makes no movement to command and is unable to communicate. He will open his eyes to a loud noise and withdraws from a painful stimulus. Which of the following statements most accurately describes his condition?

- A. Locked-in syndrome
- B. Coma
- C. Permanent vegetative state
- D. Brain dead
- E. Minimally conscious state

Answer: E.

This patient has sustained a severe brain injury and is in a minimally conscious state. Prognosis is uncertain but after one year it becomes less likely that meaningful recovery will occur. Traumatic brain injury appears to recover to a certain extent more frequently than other aetiologies. The

difference between a vegetative state and minimally conscious state is subtle and requires an expert in neuro-rehabilitation to differentiate accurately. The diagnosis of permanent vegetative state requires it to be ongoing for greater than one year (see [Box 9.52](#)).

9.4. A 65-year-old woman is recovering from bacterial pneumonia in intensive care. She has failed extubation twice and a percutaneous tracheostomy is planned. When explaining the process of a tracheostomy to the next of kin, which of the following statements is true?

- A. A percutaneous tracheostomy is considerably safer than a surgical tracheostomy
- B. Infection at the tracheostomy site is extremely rare
- C. The patient will require moderate levels of sedation to tolerate the tracheostomy after the procedure
- D. Long-term complications such as tracheal stenosis are comparable to complication rates from prolonged oral-tracheal intubation
- E. The patient will not be able to talk or eat until the tracheostomy is removed

Answer: D.

Tracheostomy is frequently performed when a patient is unable to be successfully extubated and is a useful bridge to extubation allowing incremental reduction in support, cessation of sedation and, as weaning continues, the facility to talk (using a one-way valve on the breathing circuit and a deflated tracheostomy cuff). Swallowing can be assessed and diet commenced if appropriate. Surgical and percutaneous tracheostomy both have similar complication rates (comparative studies are skewed by the population, i.e. surgical tracheostomy is often performed on more difficult anatomy). There are insufficient data to demonstrate that a tracheostomy is safer in the long term than a prolonged intubation and probably has a comparable complication rate, albeit with less laryngeal damage but more distal airway pathology.

9.5. Severe lactic acidosis (> 10 mmol/L/ 90 mg/dL) is characteristic of the following scenarios except which?

- A. Sulphonylurea overdose
- B. Ingestion of anti-freeze (ethylene glycol)
- C. Metformin use with acute kidney injury
- D. Diarrhoea and vomiting in a patient with pyruvate decarboxylase deficiency
- E. Adrenaline (epinephrine) infusion for anaphylaxis

Answer: A.

Severe lactic acidosis regardless of cause is associated with a high mortality. Classic causes include metformin (overdose or accumulation), adrenaline infusion and certain enzyme deficiencies. Ethylene glycol typically causes an erroneously elevated lactate on the blood gas analysis (less elevated on venous lactate – termed the 'lactate gap'), however there is still frequently a coexisting genuine lactate acidosis. Profound hypoglycaemia is the usual presenting feature of sulphonylurea overdose.

9.6. A 72-year-old woman with mild COPD is recovering after coronary artery bypass grafts. She has sustained a stroke during the operation and has a dense left hemiparesis. Today she has developed a high temperature and rigors. Which of the following statements is most accurate?

- A. Administration of broad-spectrum antibiotics and 50 mL/kg of fluid in the first 2 hours would be appropriate
- B. High-flow oxygen should be commenced to obtain a SpO<sub>2</sub> of 98%–100%

- C. Three sets of peripheral cultures should be taken before commencing antibiotics as endocarditis is a possibility
- D. A saturation target of 94%–98% is appropriate
- E. The lactate should be measured and if greater than 5 mmol/L, an infusion of sodium bicarbonate should be given

Answer: D.

The 'Sepsis Six' interventions are well recognised as the first response to suspected sepsis (Box 9.33). Up to 30 mL/kg of fluid may be appropriate, a set of blood cultures should be drawn but three sets will likely delay the administration of antibiotics. Sodium bicarbonate is not usually given for a raised anion gap acidosis (such as lactic acidosis). Oxygen should be titrated to saturations of 92%–96%. Less than this reduces oxygen delivery and more than this exposes the patient to risks of hyperoxia (especially important following a stroke).

- 9.7. A 65-year-old man with peripheral vascular disease is admitted to hospital with severe abdominal pain. He has lost 10 kg of weight in the past 2 months. The abdomen is soft but diffusely tender. He is febrile, tachycardic and hypotensive. The venous lactate is 1.2 mmol/L (10 mg/dL) and the haemoglobin is 15 g/L, a creatinine of 212 µmol/L (2.4 mg/dL) from a baseline of 106 µmol/L (1.4 mg/dL). Which of the following statements is most correct?
- A. The normal lactate virtually excludes ischaemic gut as a diagnosis
  - B. Broad-spectrum antibiotics should be given to treat for potential gut translocation of bacteria
  - C. A non-contrast CT should be performed as there is an acute kidney injury
  - D. The normal haemoglobin makes bleeding very unlikely to be the cause
  - E. CT scan can wait until the following day to allow for resuscitation and conservative management to improve his condition

Answer: B.

Ischaemic gut is certainly possible in this scenario (as is undiagnosed abdominal malignancy). Lactate may remain normal in gut ischaemia until the later stages as hepatic clearance becomes saturated. Risks of a delayed diagnosis are greater than those of renal injury from contrast. Contrast is essential in making diagnostic decisions from the CT abdomen; this patient warrants urgent investigation. Haemoglobin does not usually reduce significantly in acute bleeding until the patient receives IV volume replacement so this could still be haemorrhage. Bacterial translocation and sepsis are common in the acute abdomen and broad-spectrum antibiotics should be administered early.

- 9.8. A woman is undergoing brainstem death (BSD) testing following a massive intracranial haemorrhage. The CT head scan shows a large haemorrhage in the basal ganglia with extension into the lateral ventricles bilaterally, the 3rd and 4th ventricles, with marked hydrocephalus and early tentorial herniation. Which of the following statements is true?
- A. The absence of a doll's head reflex is part of the UK BSD criteria
  - B. A temperature of 35.9°C precludes BSD testing at this time
  - C. Peripheral movements on supra-orbital pressure are just a spinal reflex and do not prevent a diagnosis of BSD to be made
  - D. The presence of seizures at presentation does not preclude the performance of BSD testing
  - E. At the end of the apnoea test, following the absence of all other brainstem reflexes some very shallow breaths are noted. The patient can still be pronounced brain dead

Answer: D.

Brain death testing must leave no room for uncertainty; where uncertainty exists the tests should be delayed, abandoned or auxiliary investigations should be undertaken, such as a perfusion brain scan or levels of some longer-acting sedative drugs. In this case the only correct answer is that seizures on presentation do not preclude the diagnosis. Absence of doll's head reflex, although suggestive of a major brain injury, does not form part of the UK test. Peripheral movements occurring on supra-orbital pressure would suggest that brain death has not occurred although occasional spontaneous peripheral movements in isolation may be spinal reflexes (see Box 9.51).

- 9.9. A 36-year-old woman presents one month post-partum. She has been referred into the medical unit with a severe headache and concerns that it could be a subarachnoid haemorrhage. The pain is mainly frontal, and described as a band across the front and top of her head. The pain came on acutely this morning but maximal intensity developed over the course of an hour. It did not have a postural element and has eased slightly with simple analgesia. On questioning she says it has been present on and off for the past three weeks. The CT brain has been reported as normal. She is afebrile, does not look unwell, has no abnormal neurology and has normal inflammatory markers although is still in quite some discomfort. Her blood pressure is 105/70 mmHg and heart rate is 60. What is the most appropriate next investigation?
- A. Lumbar puncture and oligo-clonal bands
  - B. Lumbar puncture and xanthochromia
  - C. MRI brain
  - D. Erythrocyte sedimentation rate (ESR)
  - E. EEG

Answer: C.

This scenario could just be a tension-type headache as there are no adverse features. However, there is some increased risk of venous sinus thrombosis in the peri-partum period and the severity of the headache warrants further investigation. A subarachnoid haemorrhage is unlikely given the history and normal CT, and temporal arteritis is also unlikely. A CT angiogram/venogram to look for cerebral aneurysm or sinus thrombosis would be a reasonable next step but would expose the patient to additional radiation, so if an MRI is available that is the investigation of choice.

# Poisoning

## Comprehensive evaluation of the poisoned patient 220

### General approach to the poisoned patient 222

- Triage and resuscitation 222
- Clinical assessment and investigations 222
- Psychiatric assessment 223
- General management 223

## i

### Taking a history in poisoning

- What toxin(s) have been taken and how much?
- What time were they taken and by what route?
- Have alcohol or other substances (including drugs of misuse) also been taken?
- Obtain details from witnesses (e.g. family, friends, ambulance personnel) of the circumstances of the overdose
- Assess immediate suicide risk in those with apparent self-harm (full psychiatric evaluation when patient has recovered physically)
- Assess capacity to make decisions about accepting or refusing treatment
- Establish past medical history, drug history and allergies, social and family history
- Record all information carefully

Clinical signs of poisoning by pharmaceutical agents and drugs of misuse.

Decontamination and enhanced elimination. One of the key aspects in the evaluation of a poisoned patient is deciding if decontamination and/or enhanced elimination is required.

Acute poisoning is common, accounting for about 1% of hospital admissions in the UK. Common or otherwise important substances involved are shown in [Box 10.1](#). In high-income countries, the most frequent cause is intentional drug overdose in the context of self-harm, often involving prescribed or 'over-the-counter' medicines. Accidental poisoning is also common, especially in children and older people ([Box 10.2](#)). Toxicity also results from alcohol or recreational substance use and following occupational or environmental exposure. Criminal poisoning may also occur, including drug-facilitated robbery or sexual assault. Poisoning is a major cause of death in young adults; most deaths occur before patients reach medical attention, while overall mortality is low (<1%) in those admitted to hospital.

In low- and middle-income countries, the frequency of self-harm is more difficult to estimate. Because of their widespread availability and use, household and agricultural products, such as pesticides and herbicides, are common sources of poisoning and have a much higher case fatality. In China and South-east Asia, pesticides account for about 300 000 suicides each year. Snake bite and other forms of envenomation are also important causes of morbidity and mortality internationally and are discussed in Chapter 11.

## i

### 10.1 Important substances involved in poisoning

#### In the UK

- Analgesics: paracetamol and non-steroidal anti-inflammatory drugs (NSAIDs)
- Antidepressants: selective serotonin re-uptake inhibitors (SSRIs), serotonin-norepinephrine re-uptake inhibitors, tricyclic antidepressants (TCAs) and lithium
- Cardiovascular agents:  $\beta$ -blockers, calcium channel blockers and cardiac glycosides
- Drugs of misuse: depressants (e.g. opiates, benzodiazepines), stimulants and entactogens (e.g. amphetamines, MDMA, mephedrone, cocaine), hallucinogens (e.g. cannabis, synthetic cannabinoid receptor agonists)
- Carbon monoxide
- Alcohol

#### In South and South-east Asia

- Organophosphorus and carbamate insecticides
- Aluminium and zinc phosphide
- Paraquat
- Oleander
- Corrosives
- Snake and insect venoms ([Ch. 11](#))

(MDMA = 3,4-methylene-dioxymethamphetamine, ecstasy)

### 10.2 Poisoning in old age

- **Aetiology:** may result from accidental poisoning (e.g. due to delirium or dementia) or drug toxicity as a consequence of impaired renal or hepatic function or drug interaction. Toxic prescription medicines are more likely to be available.
- **Psychiatric illness:** self-harm is less common than in younger adults, but more frequently associated with depression and other psychiatric illness, as well as chronic illness and pain. There is a higher risk of subsequent suicide.
- **Severity of poisoning:** increased morbidity and mortality result from reduced renal and hepatic function, lower functional reserve, increased sensitivity to sedative agents and frequent comorbidity.

## General approach to the poisoned patient

A general approach is shown on pages 220–221. In many countries, poisons centres are available to provide advice on management of suspected poisoning with specific substances and the use of antidotes. Information is also available online see 'Further information'.

## i

### 10.3 Substances of very low toxicity

- Writing/educational materials, e.g. pencil lead, crayons, chalk
- Decorating products, e.g. emulsion paint, wallpaper paste
- Cleaning/bathroom products (except dishwasher tablets and liquid laundry detergent capsules, which can be corrosive)
- Pharmaceuticals: oral contraceptives, most antibiotics (but not tetracyclines or antituberculous drugs), vitamins B, C and E, prednisolone, emollients and other skin creams, baby lotion
- Miscellaneous: Plasticine, silica gel, most household plants, plant food, pet food, soil

## Triage and resuscitation

Patients who are seriously poisoned must be identified early so that appropriate management is not delayed. Triage involves:

- immediately assessing vital signs
- identifying the poison(s) involved and obtaining adequate information about them
- identifying patients at risk of further attempts at self-harm and removing any remaining hazards.

Those with possible external contamination with chemical or environmental toxins should undergo appropriate decontamination (p. 221). Critically ill patients must be resuscitated (p. 176).

The Glasgow Coma Scale (GCS) is commonly employed to assess conscious level, although not specifically validated in poisoning. The AVPU (alert/verbal/painful/unresponsive) scale is also a rapid and simple method. An electrocardiogram (ECG) should be performed and cardiac monitoring instituted in all patients with cardiovascular features or where exposure to potentially cardiotoxic substances is suspected. Patients who may need antidotes should be weighed if possible, so that appropriate weight-related doses can be prescribed.

Substances involved that are unlikely to be toxic in humans should be identified so that inappropriate admission and intervention are avoided ([Box 10.3](#)).

## Clinical assessment and investigations

History and examination are described on page 220. Occasionally, patients may be unaware of or confused about what they have taken, or may exaggerate (or, less commonly, underestimate) the size of the overdose, but rarely mislead medical staff deliberately. Multiple drug exposure (including alcohol) is common in episodes of self-harm or recreational use. It is important to obtain information on all substances involved and consider the potential toxicity of the combinations that may be involved. In regions of the world where self-poisoning is illegal, patients may be reticent about giving a history.

Toxic causes of abnormal physical signs are shown on page 221. The patient may have a cluster of clinical features ('toxidrome') suggestive of poisoning with a particular drug type, such as the anticholinergic, serotonergic (see [Box 10.10](#)), stimulant, sedative, opioid (see [Box 10.12](#)) and cholinergic (see [Box 10.14](#)) feature clusters. Poisoning is a common cause of coma, especially in younger people, but it is important to exclude other potential causes (see [Box 9.31](#)).

Urea, electrolytes and creatinine should be measured in all patients with suspected systemic poisoning. Arterial blood gases should be checked in those with significant respiratory or circulatory compromise, or after poisoning with substances likely to affect acid–base status ([Box 10.4](#)). Calculation of anion and osmolar gaps may help to inform diagnosis and management ([Box 10.5](#)). Potent oxidising agents may cause methaemoglobinemia, with consequent blue discoloration of skin and blood, and reduced tissue oxygen delivery ([Fig. 10.1](#)).

For some substances, management may be facilitated by measurement of the amount of toxin in the blood. Qualitative urine screens for potential toxins, including near-patient testing kits, have a limited clinical role.

## Psychiatric assessment

Patients presenting with drug overdose in the context of self-harm should undergo psychiatric evaluation prior to discharge by a health professional with appropriate training (see p. 1243). This should occur after they have recovered from poisoning, unless there is an urgent issue, such as uncertainty about their capacity to decline medical treatment.

## General management

Patients presenting with eye/skin contamination should undergo local decontamination measures. These are described on page 221.

## Gastrointestinal decontamination

Patients who have ingested toxins in potentially harmful amounts may be considered for gastrointestinal decontamination if poisoning has been recent.

### Activated charcoal

Given orally as a slurry, activated charcoal absorbs toxins in the bowel as a result of its large surface area. It can prevent absorption of an important proportion of the ingested dose of toxin, but efficacy decreases with time. Activated charcoal is most effective if given within 1 hour of overdose, but may have useful efficacy later than this, for example if a sustained-release preparation has been taken or when gastric emptying is delayed. Use is ineffective for some toxins that do not bind to activated charcoal (Box 10.6). In patients with impaired swallowing or a reduced level of consciousness, activated charcoal given via a nasogastric tube carries a risk of aspiration pneumonitis, but this can be reduced (though not eliminated) by protecting the airway using a cuffed endotracheal tube.

Multiple doses of oral activated charcoal (50g 6 times daily in an adult) may enhance the elimination of some substances at any time after poisoning (Box 10.7). This interrupts enterohepatic circulation or reduces the concentration of free drug in the gut lumen, to the extent that drug diffuses from the blood back into the bowel to be absorbed on to the charcoal ('gastrointestinal dialysis'). A laxative is generally given with the charcoal to reduce the risk of constipation or intestinal obstruction by charcoal 'briquette' formation in the gut lumen.

Evidence suggests that single or multiple doses of activated charcoal do not improve clinical outcomes after poisoning with pesticides or oleander.

### Gastric aspiration and lavage

Gastric aspiration and/or lavage is very infrequently indicated in acute poisoning, as it is no more effective than activated charcoal for most substances and complications are common, especially pulmonary aspiration.

10

### 10.4 Causes of acidosis in the poisoned patient

Cause	Normal lactate*	High lactate
<b>Toxic</b>	Salicylates Methanol Ethylene glycol Paraldehyde	Metformin Iron Cyanide Sodium valproate Carbon monoxide
<b>Other</b>	Renal failure Ketoacidosis Severe diarrhoea	Shock

\*Unless circulatory shock is present, when it will be high in any case.

### 10.5 Anion and osmolar gaps in poisoning

	Anion gap	Osmolar gap
<b>Calculation</b>	$[Na^+ + K^+] - [Cl^- + HCO_3^-]$	$[\text{Measured osmolality}] - [(2 \times Na) + \text{Urea} + \text{Glucose}]^1$
<b>Reference range</b>	12–16 mmol/L	<10
<b>Common toxic causes of elevation<sup>2</sup></b>	Ethanol Ethylene glycol Methanol Salicylates Iron Cyanide	Ethanol Ethylene glycol Methanol

<sup>1</sup>All units should be in mmol/L, except osmolality, which should be in mOsmol/kg. For non-SI units, the corresponding formula is  $[\text{Measured osmolality (mOsmol/kg)}] - [(2 \times Na (mEq/L)) + \text{Urea}/2.8 (mg/dL) + \text{Glucose}/18 (mg/dL)]$ . <sup>2</sup>Box 19.19 gives non-toxic causes.

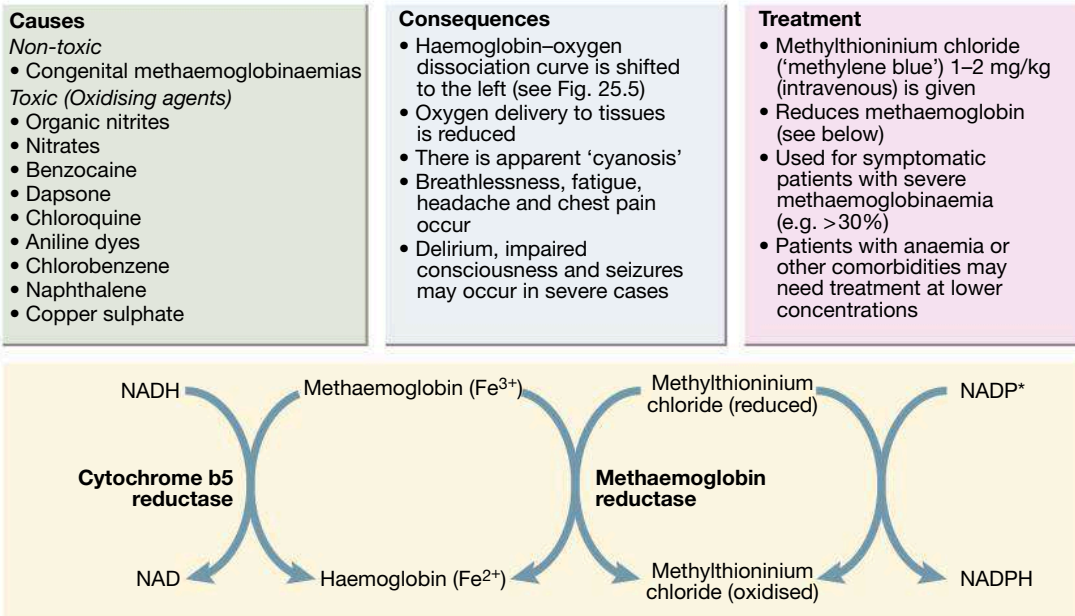

Fig. 10.1 Methaemoglobinaemia. (NAD = nicotinamide adenine dinucleotide, H = hydrogen, P = phosphate)

10.6 Substances poorly adsorbed by activated charcoal	
<b>Medicines</b>	
• Iron	• Lithium
<b>Chemicals</b>	
• Acids*	• Mercury
• Alkalis*	• Methanol
• Ethanol	• Petroleum distillates*
• Ethylene glycol	
*Gastric lavage contraindicated.	

10.7 Examples of poisons effectively eliminated by multiple doses of activated charcoal, haemodialysis or haemoperfusion	
<b>Multiple doses of activated charcoal</b>	
• Carbamazepine	• Quinine
• Dapsone	• Theophylline
• Phenobarbital	
<b>Haemodialysis</b>	
• Ethylene glycol	• Salicylates
• Isopropanol	• Sodium valproate
• Methanol	• Lithium
<b>Haemoperfusion</b>	
• Theophylline	• Phenobarbital
• Phenytoin	• Amobarbital
• Carbamazepine	

It is contraindicated if strong acids, alkalis or petroleum distillates have been ingested. Use may be justified for life-threatening overdoses of those substances that are not absorbed by activated charcoal (see [Box 10.6](#)).

### Whole bowel irrigation

This involves the administration of large quantities of osmotically balanced polyethylene glycol and electrolyte solution (1–2L/hr for an adult), usually by a nasogastric tube, until the rectal effluent is clear. It is occasionally indicated to enhance the elimination of ingested packets of illicit drugs or slow-release tablets such as iron and lithium that are not absorbed by activated charcoal. Contraindications include inadequate airway protection, haemodynamic instability, gastrointestinal haemorrhage, obstruction or ileus. Whole bowel irrigation may precipitate nausea and vomiting, abdominal pain and electrolyte disturbances.

### Urinary alkalinisation

Urinary excretion of weak acids and bases is affected by urinary pH, which changes the extent to which they are ionised. Highly ionised molecules pass poorly through lipid membranes and therefore little tubular reabsorption occurs and urinary excretion is increased. If the urine is alkalinised (pH > 7.5) by the administration of sodium bicarbonate (e.g. 1.5L of 1.26% sodium bicarbonate over 2hrs), weak acids (e.g. salicylates, methotrexate) are highly ionised, resulting in enhanced urinary excretion.

Urinary alkalinisation is currently recommended for patients with clinically significant salicylate poisoning when the criteria for haemodialysis are not met (see below). It is also sometimes used for poisoning with methotrexate. Complications include alkalaemia, hypokalaemia and occasionally alkalotic tetany (Ch. 19). Hypocalcaemia may occur, but is rare.

### Haemodialysis and haemoperfusion

These techniques can enhance the elimination of poisons that have a small volume of distribution and a long half-life after overdose; use is appropriate when poisoning is sufficiently severe. The toxin must be small

enough to cross the dialysis membrane (haemodialysis) or must bind to activated charcoal (haemoperfusion) (see [Box 10.7](#)). Haemodialysis can also correct acid–base and metabolic disturbances associated with poisoning.

### Lipid emulsion therapy

Lipid emulsion therapy is increasingly used for poisoning with lipid-soluble agents. Evidence for efficacy is most compelling for local anaesthetics, especially bupivacaine. The treatment has also been used with anecdotal reports of success for poisoning with tricyclic antidepressants, calcium channel blockers and lipid-soluble  $\beta$ -adrenoceptor antagonists ( $\beta$ -blockers) such as propranolol. It involves intravenous administration of 20% lipid emulsion (e.g. Intralipid, suggested initial dose 1.5 mL/kg, followed by a continued infusion of 0.25 mL/kg/min until there is clinical improvement). It is thought that lipid-soluble toxins partition into the intravenous lipid, reducing target tissue concentrations. The elevated myocardial free fatty acid concentrations may also have beneficial effects on myocardial metabolism and performance by counteracting the inhibition of myocardial fatty acid oxidation produced by some cardiotoxins, enabling increased adenosine triphosphate (ATP) synthesis and energy production. Some animal studies have suggested efficacy and case reports of use in human poisoning have also been encouraging, with recovery of circulatory collapse reported in cases where other treatment modalities have been unsuccessful. No controlled trials of this technique have been performed, however, and efficacy remains uncertain, especially for substances other than local anaesthetics.

### Supportive care

For most poisons, antidotes and methods to accelerate elimination are inappropriate, unavailable or incompletely effective. Outcome is dependent on appropriate nursing and supportive care, and treatment of complications ([Box 10.8](#)).

### Antidotes

Antidotes are available for some poisons and work by a variety of mechanisms ([Box 10.9](#)). The use of some of these in the management of specific poisons is described below.

## Poisoning by specific pharmaceutical agents

### Analgesics

#### Paracetamol

Paracetamol (acetaminophen) is the drug most commonly used in overdose in the UK. Toxicity is caused by an intermediate reactive metabolite that binds covalently to cellular proteins, causing cell death. This results in hepatic and occasionally renal failure. In therapeutic doses, the toxic metabolite is detoxified in reactions requiring glutathione, but in overdose, glutathione reserves become exhausted.

#### Management

Activated charcoal may be used in patients presenting within 1 hour. Antidotes for paracetamol act by replenishing hepatic glutathione, and acetylcysteine is the most commonly used. It should be administered to all patients with acute poisoning and paracetamol concentrations above a 'treatment line' provided on paracetamol poisoning nomograms ([Fig. 10.2](#)). The threshold used for these nomograms varies between countries, however, and local guidance should be followed. Liver and renal function, International Normalised Ratio (INR) and a venous bicarbonate should also be measured. Arterial blood gases and lactate should be assessed in patients with reduced bicarbonate or severe liver function abnormalities; metabolic acidosis indicates severe poisoning.

10.8 Complications of poisoning and their management		
Complication	Examples of causative agents	Management
<b>Coma</b>	Sedative agents	Appropriate airway protection and ventilatory support Oxygen saturation and blood gas monitoring Pressure area and bladder care Identification and treatment of aspiration pneumonia
<b>Seizures</b>	NSAIDs Anticonvulsants TCAs Theophylline	Appropriate airway and ventilatory support IV benzodiazepine (e.g. diazepam 10–20 mg or lorazepam 2–4 mg) Correction of hypoxia, acid–base and metabolic abnormalities
<b>Acute dystonias</b>	Typical antipsychotics Metoclopramide	Procyclidine, benztropine or diazepam
<b>Hypotension</b>		
Due to vasodilatation	Vasodilator antihypertensives Anticholinergic agents TCAs	IV fluids Vasopressors (rarely indicated; p. 210)
Due to myocardial suppression	$\beta$ -blockers Calcium channel blockers TCAs	Optimisation of volume status Inotropic agents (p. 210)
<b>Ventricular tachycardia</b>		
Monomorphic, associated with QRS prolongation	Sodium channel blockers	Correction of electrolyte and acid–base abnormalities and hypoxia Sodium bicarbonate (e.g. 50 mL 8.4% solution, repeated if necessary)
Torsades de pointes, associated with QT <sub>c</sub> prolongation	Anti-arrhythmic drugs (quinidine, amiodarone, sotalol) Antimalarials Organophosphate insecticides Antipsychotic agents Antidepressants Antibiotics (erythromycin)	Correction of electrolyte and acid–base abnormalities and hypoxia Magnesium sulphate, 2 g IV (adults) over 1–2 mins, repeated if necessary
(IV = intravenous; NSAID = non-steroidal anti-inflammatory drug; TCA = tricyclic antidepressant)		

If multiple ingestions of paracetamol have taken place over several hours ('staggered overdose') or days (e.g. chronic therapeutic excess), acetylcysteine may be indicated, but paracetamol treatment nomograms are not useful for assessing this; specific treatment recommendations are based on the reported dose ingested and vary between countries.

When indicated, acetylcysteine given intravenously (or orally in some countries) is highly efficacious if administered within 8 hours of overdose. However, efficacy declines thereafter, so administration should not be delayed to await a paracetamol blood concentration result in patients presenting after 8 hours. The antidote can be stopped if the paracetamol concentration is subsequently shown to be below the nomogram treatment line. High-dose acetylcysteine regimens are increasingly used in patients with very large paracetamol overdoses.

Non-allergic anaphylactic ('anaphylactoid') reactions are the most important adverse effects of acetylcysteine and are caused by dose-related histamine release. Common features are itching and urticaria, and in severe cases, bronchospasm and hypotension. Most cases can be

10.9 Specific antidotes used to treat poisoning		
Mechanism of action	Examples of antidote	Poisoning treated
<b>Receptor antagonists</b> (block actions of toxin)	Naloxone Flumazenil Atropine	Opioids Benzodiazepines Organophosphorus compounds Carbamates
<b>Effects on enzymes</b> Correct functional deficiencies		
Glutathione	Acetylcysteine Methionine	Paracetamol
Pyridoxine	Pyridoxine	Isoniazid
Vitamin K	Vitamin K	Warfarin
Alcohol dehydrogenase inhibitors (prevent formation of toxic metabolites)	Fomepizole Ethanol	Ethylene glycol Methanol
Cholinesterase reactivators (restore cholinesterase function)	Pralidoxime Obidoxime	Organophosphorus compounds
<b>Hydrolysing enzymes</b> (metabolise toxin)	Glucarpidase	Methotrexate
<b>Rhodanase enhancers</b> (enhance enzyme-related detoxification by donating sulphur)	Sodium thiosulphate	Cyanide
<b>Binding agents</b> (prevent toxicity by binding to toxin)		
Chelating agents	Desferrioxamine Hydroxocobalamin Dicobalt edetate DMSA Sodium calcium edetate Protamine	Iron Cyanide Lead
Decoy receptor	Andexanet alfa,	Apixaban, rivaroxaban
Antibody fragments	Digoxin Fab fragments Idarucizumab	Digoxin Dabigatran etexilate
<b>Reducing agents</b> (convert methaemoglobin to haemoglobin)	Methylthionium chloride	Aniline dyes, organic nitrites, phenacetin, sulphonamides
<b>Oxidising agents</b> (convert haemoglobin to methaemoglobin, which has high affinity for binding cyanide)	Sodium nitrite	Cyanide
(DMSA = dimercaptosuccinic acid)		

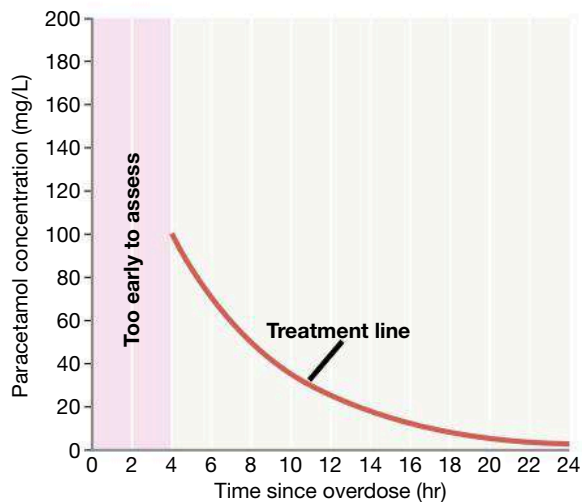

managed by temporary discontinuation of acetylcysteine and administration of an antihistamine.

An alternative antidote is methionine 2.5 g orally (adult dose) every 4 hours to a total of four doses, but this may be less effective, especially after delayed presentation. Liver transplantation should be considered for paracetamol poisoning with life-threatening liver failure (p. 872).

## Salicylates (aspirin)

### Clinical features

Salicylate overdose commonly causes nausea, vomiting, sweating, tinnitus and deafness. Direct stimulation of the respiratory centre produces

**Fig. 10.2** Paracetamol treatment nomogram (UK). Above the treatment line, benefits of treatment outweigh risk. Below it, risks of treatment outweigh benefits.

hyperventilation and respiratory alkalosis. Peripheral vasodilatation with bounding pulses and profuse sweating occurs in moderately severe cases. Serious poisoning is associated with metabolic acidosis, hypoprothrombinaemia, hyperglycaemia, hyperpyrexia, renal failure, pulmonary oedema, shock and cerebral oedema. Agitation, delirium, coma and fits may occur, especially in children. Toxicity is enhanced by acidosis, which increases salicylate transfer across the blood–brain barrier.

### Management

Activated charcoal should be administered if the patient presents sufficiently early. Multiple doses may enhance salicylate elimination, but are not routinely recommended.

The plasma salicylate concentration should be measured at least 2 (symptomatic patients) or 4 hours (asymptomatic patients) after overdose and repeated in suspected serious poisoning, as concentrations may continue to rise for several hours. Clinical status, however, is more important than the salicylate concentration when assessing severity.

Dehydration should be corrected carefully because of the risk of pulmonary oedema. Metabolic acidosis should be treated with intravenous sodium bicarbonate (8.4%), after plasma potassium has been corrected. Urinary alkalinisation is indicated for adults with salicylate concentrations above 500 mg/L.

Haemodialysis is very effective for removing salicylate and correcting associated acid–base and fluid balance abnormalities. It should be considered when serum concentrations are above 700 mg/L in adults with severe toxic features, or in renal failure, pulmonary oedema, coma, convulsions or refractory acidosis.

## Non-steroidal anti-inflammatory drugs

### Clinical features

Overdose of most non-steroidal anti-inflammatory drugs (NSAIDs) usually causes only minor abdominal discomfort, vomiting and/or diarrhoea, but convulsions can occur occasionally, especially with mefenamic acid. Coma, prolonged seizures, apnoea, liver dysfunction and renal failure may follow substantial overdose but are rare. Features of toxicity are unlikely to develop in patients who are asymptomatic more than 6 hours after overdose.

### Management

Electrolytes, liver function tests and a full blood count should be checked in all but the most trivial cases. Activated charcoal may be given if the patient presents within 1 hour. Symptomatic treatment for nausea and gastrointestinal irritation may be needed.

## Antidepressants

### Tricyclic antidepressants

Overdose with tricyclic antidepressants (TCAs) carries a high morbidity and mortality because of their sodium channel-blocking, anticholinergic and  $\alpha$ -adrenoceptor-blocking effects.

### Clinical features

Anticholinergic effects are common (Box 10.10). Severe complications include convulsions, coma and arrhythmias (ventricular tachycardia, ventricular fibrillation and, less commonly, heart block). Hypotension results from inappropriate vasodilatation or impaired myocardial contractility. Serious complications appear more common with dosulepin and amitriptyline.

### Management

Activated charcoal should be administered if the patient presents within 1 hour. A 12-lead ECG should be taken and continuous cardiac monitoring maintained for at least 6 hours. Prolongation of the QRS interval (especially if  $>0.16$  secs) indicates severe sodium channel blockade and a high risk of arrhythmia (Fig. 10.3). QT interval prolongation may also occur. Arterial blood gases should be measured in suspected severe poisoning.

In patients with arrhythmias, significant QRS or QT prolongation or acidosis, intravenous sodium bicarbonate (50 mL of 8.4% solution) should be administered and repeated to correct pH. The correction of the acidosis and the increased extracellular sodium loading that improve sodium channel function and may bring about rapid improvement in ECG features and arrhythmias. Hypoxia and electrolyte abnormalities should also be corrected. Anti-arrhythmic drugs should be given only on specialist

### 10.10 Anticholinergic and serotonergic feature clusters

	Anticholinergic	Serotonin syndrome
<b>Common causes</b>	Benzodiazepines Antipsychotics TCAs Antihistamines Scopolamine Benzatropine Belladonna Some plants and mushrooms (see Box 10.18)	SSRIs MAOIs TCAs Amphetamines Tryptamines Buspirone Bupropion (especially in combination)
<b>Clinical features</b>		
Cardiovascular	Tachycardia, hypertension	Tachycardia, hyper- or hypotension
Central nervous system	Delirium, hallucinations, sedation	Delirium, hallucinations, sedation, coma
Muscle	Myoclonus	Shivering, tremor, myoclonus, raised creatine kinase
Temperature	Fever	Fever
Eyes	Diplopia, mydriasis	Normal pupil size
Abdomen	Ileus, palpable bladder	Diarrhoea, vomiting
Mouth	Dry	
Skin	Flushing, hot, dry	Flushing, sweating
<b>Complications</b>	Seizures	Seizures Rhabdomyolysis Renal failure Metabolic acidosis Coagulopathies

(MAOI = monoamine oxidase inhibitor; SSRI = selective serotonin re-uptake inhibitor; TCA = tricyclic antidepressant)

**Fig. 10.3** ECG in severe tricyclic antidepressant poisoning. This rhythm strip shows a broad QRS complex due to impaired conduction.

advice. Prolonged seizures should be treated initially with intravenous benzodiazepines (see [Box 10.8](#)).

### Selective serotonin and noradrenaline re-uptake inhibitors

Selective serotonin re-uptake inhibitor (SSRI) antidepressants (e.g. fluoxetine, paroxetine, fluvoxamine, sertraline, citalopram, escitalopram) are commonly used to treat depression and are less toxic in overdose than TCAs. The related serotonin–noradrenaline re-uptake inhibitors (SNRIs), such as venlafaxine and duloxetine, are also commonly used and are more toxic than SSRIs in overdose. The pre-synaptic  $\alpha_2$ -antagonist mirtazapine, which increases central noradrenergic and serotonergic neurotransmission, is also increasingly encountered in overdose.

#### Clinical features and management

Overdose of SSRIs may produce nausea and vomiting, tremor, insomnia and sinus tachycardia. Agitation, drowsiness and convulsions occur infrequently and may be delayed for several hours. Serotonin syndrome may occur (see [Box 10.10](#)), especially if SSRIs are taken in combination or with other serotonergic agents. Cardiac arrhythmias occur infrequently and most patients require supportive care only. The toxic effects of SNRIs are similar but tachycardia, hypertension or hypotension and ECG changes (QRS and QT prolongation) may be more prominent and hypoglycaemia can also arise. Mirtazapine has lower toxicity, but high doses may cause sedation, tachycardia and serotonin syndrome.

### Lithium

Severe lithium toxicity is uncommon after intentional acute overdose, but is more often encountered in patients taking therapeutic doses as a result of interactions with drugs such as diuretics or NSAIDs or because of worsening renal function. Severe toxicity is more common after acute overdose in patients already taking chronic therapy ('acute on chronic' poisoning).

#### Clinical features

Nausea, diarrhoea, polyuria, dizziness and tremor may progress to muscular weakness, drowsiness, delirium, myoclonus, fasciculations, choreoathetosis and renal failure. Coma, seizures, ataxia, cardiac dysrhythmias such as heart block, blood pressure disturbances and renal failure may occur in severe poisoning.

#### Management

Activated charcoal is ineffective. Early gastric lavage is of theoretical benefit, but lithium tablets are likely to remain intact in the stomach and may be too large for aspiration via a lavage tube. Whole bowel irrigation is often used after substantial overdose, but efficacy is unproven.

Lithium concentrations should be measured immediately (symptomatic patients) or after at least 6 hours (asymptomatic patients) following acute overdose. The usual therapeutic range is 0.4–1.0 mmol/L. Adequate hydration should be maintained with intravenous fluids. Seizures should be treated as in [Box 10.8](#).

Haemodialysis should be considered for severe toxicity associated with high lithium concentrations (e.g. >4.0 mmol/L after chronic or 'acute on chronic' poisoning, or >7.5 mmol/L after acute poisoning). Lithium

concentrations are reduced substantially during dialysis, but rebound increases occur after discontinuation and multiple sessions are usually required.

### Cardiovascular medications

Although not common, cardiovascular drug overdose is important because features of toxicity are often severe.

#### Beta-blockers

Major features of toxicity are bradycardia and hypotension; heart block, pulmonary oedema and cardiogenic shock occur in severe poisoning. Those with additional sodium channel-blocking effects (e.g. propranolol, acebutolol, carvedilol) may cause seizures, delirium and coma, while sotalol, which also blocks potassium channels, may cause QT<sub>c</sub> prolongation and torsades de pointes (see [Box 10.8](#) and p. 418).

#### Management

Intravenous fluids may reverse hypotension, but care is required to avoid pulmonary oedema. Bradycardia and hypotension may respond to high doses of atropine (up to 3 mg in an adult) or an infusion of isoproterenol. Glucagon (5–10 mg IV over 10 mins, then 50–150 microgram/kg/hr by infusion) counteracts  $\beta$ -blockade by stimulating intracellular cyclic adenosine monophosphate (cAMP) production and is now more commonly used. In severe cases, 'hyperinsulinaemia euglycaemic therapy' has been used, as described under calcium channel blockers below. The efficacy of lipid emulsion therapy in severe poisoning with lipid-soluble  $\beta$ -blockers, such as propranolol, carvedilol and oxprenolol, is uncertain.

#### Calcium channel blockers

In therapeutic doses, dihydropyridine calcium channel blockers (e.g. nifedipine, amlodipine) cause vasodilatation, whereas diltiazem and verapamil have predominantly cardiac effects, including bradycardia and reduced myocardial contractility. All L-type calcium channel blockers, however, are highly toxic in overdose.

#### Clinical features

Hypotension due to vasodilatation or myocardial depression is common and bradycardias and heart block may also occur, especially with verapamil and diltiazem. Gastrointestinal disturbances, delirium, metabolic acidosis, hyperglycaemia and hyperkalaemia may also be present.

#### Management

Hypotension should be corrected with intravenous fluids, taking care to avoid pulmonary oedema. Persistent hypotension may respond to intravenous calcium gluconate (10 mg IV over 5 mins, repeated as required). Isoproterenol and glucagon may also be useful. Successful use of high-dose intravenous insulin with glucose (10%–20% dextrose with insulin initially at 0.5–2.0 U/kg/hr, increasing to 5–10 U/kg/hr according to clinical response), so-called 'hyperinsulinaemia euglycaemic therapy', has been reported in patients unresponsive to other strategies. The mechanism of action remains to be fully elucidated, but in states of shock myocardial metabolism switches from use of free fatty acids to glucose. Calcium channel blocker poisoning is also associated with hypoinsulinaemia and insulin resistance, impeding glucose uptake by myocytes. High doses of insulin inhibit lipolysis and increase glucose uptake and the efficiency of glucose utilisation. Cardiac pacing may be needed for severe unresponsive bradycardias or heart block. Lipid emulsion therapy has also been used in severe poisoning with apparent benefit, although evidence is largely anecdotal.

#### Digoxin and oleander

Poisoning with digoxin (a cardiac glycoside; p. XXX) is usually accidental, arising from prescription of an excessive dose, impairment of renal function or drug interactions. In South Asia, deliberate self-poisoning with

the plant yellow oleander (*Thevetia peruviana*), which contains cardiac glycosides, is common.

### Clinical features

Cardiac effects include tachyarrhythmias (either atrial or ventricular) and bradycardias, with or without atrioventricular block. Ventricular bigeminy is common and atrial tachycardia with evidence of atrioventricular block is highly suggestive of the diagnosis. Severe poisoning is often associated with hyperkalaemia. Non-cardiac features include delirium, headache, nausea, vomiting, diarrhoea and (rarely) altered colour vision. Digoxin poisoning can be confirmed by elevated plasma concentration (usual therapeutic range 1.3–2.5 mmol/L). After chronic exposure, concentrations >5 mmol/L suggest serious poisoning, although this may sometimes also occur with lower concentrations.

### Management

Activated charcoal is commonly administered to patients presenting soon after acute ingestion, although evidence of benefit is lacking. Urea, electrolytes and creatinine should be measured, a 12-lead ECG performed and cardiac monitoring instituted. Hypoxia, hypokalaemia (sometimes caused by concurrent diuretic use), hypomagnesaemia and acidosis increase the risk of arrhythmias and should be corrected. Significant bradycardias may respond to atropine, although temporary pacing is sometimes needed. Ventricular arrhythmias may respond to intravenous magnesium (see Box 10.8). If available, digoxin-specific antibody fragments should be administered when there are severe refractory ventricular arrhythmias or bradycardias. These are effective for both digoxin and yellow oleander poisoning.

## Iron

Overdose with iron can cause severe and sometimes fatal poisoning, with toxicity of individual iron preparations related to their elemental iron content.

### Clinical features

Early features include gastrointestinal disturbance with the passage of grey or black stools, progressing to hyperglycaemia, leucocytosis, haematemesis, rectal bleeding, drowsiness, convulsions, coma, metabolic acidosis and cardiovascular collapse in severe cases. Early symptoms may improve or resolve within 6–12 hours, but hepatocellular necrosis can develop 12–24 hours after overdose and occasionally progresses to hepatic failure. Gastrointestinal strictures are late complications.

### Management

Activated charcoal is ineffective, but gastric lavage or whole bowel elimination may be considered in patients presenting soon after substantial overdose, although efficacy is unknown. Serum iron concentration should be measured at least 4 hours after overdose or earlier if there are features of toxicity. Desferrioxamine chelates iron and should be administered immediately in patients with severe features (e.g. coma, shock, metabolic acidosis, haemolysis), without waiting for serum iron concentrations, as well as symptomatic patients with high serum iron concentrations (e.g. >5 mg/L). Desferrioxamine may cause hypotension, allergic reactions and occasionally pulmonary oedema. Otherwise, treatment is supportive and directed at complications.

## Antipsychotic drugs

Antipsychotic drugs (see Box 31.26) are often prescribed for patients at high risk of self-harm or suicide and are often taken in overdose.

### Clinical features

Anticholinergic features (see Box 10.10) including drowsiness, tachycardia and hypotension are common and convulsions may occur. Acute dystonias, including oculogyric crisis, torticollis and trismus, may occur after overdose with typical antipsychotics like haloperidol or

chlorpromazine (Box 10.8). QT interval prolongation and torsades de pointes can occur with some typical (e.g. haloperidol) and atypical (e.g. quetiapine, amisulpride, ziprasidone) agents.

### Management

Activated charcoal may be of benefit if given early. Cardiac monitoring should be undertaken for at least 6 hours. Management is largely supportive, with treatment directed at complications (see Box 10.8).

## Antidiabetic agents

Overdose is uncommon, but toxic effects can be severe.

### Clinical features

Sulphonylureas, meglitinides (e.g. nateglinide, repaglinide) and parenteral insulin cause hypoglycaemia when taken in overdose, although insulin is non-toxic if ingested by mouth. The duration of hypoglycaemia depends on the half-life or release characteristics of the preparation and may be prolonged over several days with long-acting agents such as glibenclamide, insulin degludec or insulin glargine.

Features of hypoglycaemia include nausea, agitation, sweating, aggression, delirium, tachycardia, hypothermia, drowsiness, convulsions and coma (p. 719). Permanent neurological damage can occur if hypoglycaemia is prolonged. Hypoglycaemia can be diagnosed using bedside glucose strips, but venous blood should also be sent for laboratory confirmation.

Metformin is uncommonly associated with hypoglycaemia. Its major toxic effect is lactic acidosis, which can have a high mortality, and is particularly common in older patients and those with renal or hepatic impairment, or when ethanol has been co-ingested. Other features of metformin overdose are nausea, vomiting, diarrhoea, abdominal pain, drowsiness, coma, hypotension and cardiovascular collapse.

There is limited experience of overdose involving thiazolidinediones (e.g. pioglitazone) and dipeptidyl peptidase 4 (DPP-4) inhibitors (e.g. sitagliptin), but significant hypoglycaemia is unlikely.

### Management

Activated charcoal should be considered for recent substantial overdose. Venous blood glucose and urea and electrolytes should be measured and measurement repeated regularly. Hypoglycaemia should be corrected using oral or intravenous glucose (50 mL of 50% dextrose); an infusion of 10%–20% dextrose may be required to prevent recurrence. Intramuscular glucagon can be used as an alternative, especially if intravenous access is unavailable. If the patient remains hypoglycaemic in spite of these measures, subcutaneous or intravenous octreotide may be used. Failure to regain consciousness within a few minutes of normalisation of the blood glucose can indicate that a central nervous system (CNS) depressant has also been ingested, the hypoglycaemia has been prolonged, or there is another cause of coma (e.g. cerebral haemorrhage or oedema).

Arterial blood gases and plasma lactate should be taken after metformin overdose; acidosis should be corrected with intravenous sodium bicarbonate (250 mL 1.26% solution or 50 mL 8.4% solution, repeated as necessary). In severe cases, haemodialysis or haemodiafiltration is used.

## Pharmaceutical agents less commonly taken in poisoning

An overview of the clinical features and management for drugs less commonly involved in poisoning is provided in Box 10.11.

## Drugs of misuse

Drugs of misuse are common causes of toxicity causing presentation to hospitals. Management has recently become more complex because of the emergence of 'new psychoactive substances' (NPS). These are often

chemically related to traditional drugs of misuse, but with structural modifications made to evade legal control. The constituents of branded NPS products are often unknown and knowledge about the clinical features and management of NPS toxicity is limited.

## Depressants

These produce CNS depression, including drowsiness, ataxia, delirium and coma, sometimes with respiratory depression, airway compromise, aspiration pneumonia and respiratory arrest (Box 10.12). Other complications of coma include pressure blisters or sores and rhabdomyolysis. Effects are potentiated by other CNS depressants, including alcohol.

Essential supportive care is detailed in Box 10.8. Antidotes are available for some depressants.

## Benzodiazepines

Benzodiazepines (e.g. diazepam, lorazepam, midazolam) and related substances (e.g. zopiclone) are of low toxicity when taken alone in overdose, but can enhance CNS and respiratory depression when taken with other sedative agents, including alcohol or heroin. They are more hazardous in older people and those with chronic lung or neuromuscular disease (see Box 10.12). Dependency develops after chronic use over a few weeks and features of withdrawal commonly occur after rapid discontinuation of use. Highly potent novel benzodiazepines, such as etizolam, flualprazolam and flubromazolam, have recently been encountered, especially in counterfeit tablets purchased from dealers or via the internet; these can cause toxic effects after very low doses.

### 10.11 Clinical features and specific management of drugs less commonly involved in poisoning

Substance	Clinical features	Management
<b>Anticonvulsants</b>		
Carbamazepine, phenytoin	Cerebellar signs Convulsions Cardiac arrhythmias Coma	Multiple-dose activated charcoal (carbamazepine)
Sodium valproate	Coma Metabolic acidosis Hepatotoxicity	Haemodialysis for severe poisoning L-carnitine may be useful for severe cases with hyperammonaemia or hepatotoxicity
Isoniazid	Peripheral neuropathy Convulsions	Activated charcoal IV pyridoxine
Theophylline	Cardiac arrhythmias Convulsions Coma	Multiple-dose activated charcoal
<b>Antimalarial drugs</b>		
Chloroquine	Acidosis and hypokalaemia Visual loss Convulsions, coma ECG changes and arrhythmias	Correction of pH (but not potassium) Monitoring and treatment of cardiac rhythm High-dose diazepam with mechanical ventilation
Quinine	Tremor, tinnitus, deafness, ataxia, convulsions, coma Haemolysis ECG changes and arrhythmias Retinal toxicity	Correction of pH (but not potassium) Monitoring and treatment of cardiac rhythm Multiple-dose activated charcoal No effective treatment for visual loss

The specific benzodiazepine antagonist flumazenil (0.5 mg IV, repeated if needed) increases conscious level in patients with benzodiazepine overdose, but carries a risk of seizures and is contraindicated in patients co-ingesting pro-convulsants (e.g. TCAs, cocaine) and in those with a history of epilepsy.

## Opioids

Toxicity may result from misuse of illicit drugs such as heroin or from intentional or accidental overdose of medicinal opiates. In recent years, fentanyl and its analogues have increasingly been used to fortify heroin preparations in North America. These synthetic compounds are highly potent, their presence increases the risk of overdose and there has been a sharp increase in deaths related to opioid overdose in the United States and Canada.

### 10.12 Stimulant, sedative and opioid feature clusters

	Stimulant	Sedative hypnotic	Opioid
<b>Common causes</b>	Amphetamines MDMA ('ecstasy') Ephedrine Pseudoephedrine Cocaine Cannabis Phencyclidine Cathinones (e.g. mephedrone) Benzylpiperazine	Benzodiazepines Barbiturates Ethanol GHB	Heroin Morphine Methadone Fentanyl and derivatives Oxycodone Dihydrocodeine Codeine Pethidine Buprenorphine Dextropropoxyphene Tramadol
<b>Clinical features</b>			
Respiratory	Tachypnoea	Reduced respiratory rate and ventilation <sup>1</sup>	Reduced respiratory rate and ventilation
Cardiovascular	Tachycardia, hypertension	Hypotension <sup>1</sup>	Hypotension, relative bradycardia
Central nervous system	Restlessness, anxiety, anorexia, insomnia Hallucinations	Delirium, hallucinations, slurred speech Sedation, coma <sup>1</sup>	Delirium, hallucinations, slurred speech Sedation, coma <sup>2</sup>
Muscle	Tremor	Ataxia, reduced muscle tone	Ataxia, reduced muscle tone
Temperature	Fever	Hypothermia	Hypothermia
Eyes	Mydriasis	Diplopia, strabismus, nystagmus Normal pupil size	Miosis
Abdomen	Abdominal pain, diarrhoea	–	Ileus
Mouth	Dry	–	–
Skin	Piloerection	Blisters, pressure sores	Needle tracks <sup>2</sup>
<b>Complications</b>	Seizures Myocardial infarction Dysrhythmias Rhabdomyolysis Renal failure Intracerebral haemorrhage or infarction	Respiratory failure <sup>1</sup> Aspiration	Respiratory failure <sup>2</sup> Non-cardiogenic pulmonary oedema Aspiration

<sup>1</sup>Especially barbiturates. <sup>2</sup>Intravenous use. (GHB = gamma hydroxybutyrate; MDMA = 3,4-methylene-dioxymethamphetamine)

Intravenous or smoked heroin gives a rapid, intensely pleasurable experience, often accompanied by heightened sexual arousal. Physical dependence occurs within a few weeks of regular high-dose use. Withdrawal can start within 12 hours, causing intense craving, rhinorrhoea, lacrimation, yawning, perspiration, shivering, piloerection, vomiting, diarrhoea and abdominal cramps. Examination reveals tachycardia, hypertension, mydriasis and facial flushing.

Commonly encountered opioids and clinical features of poisoning are shown in [Box 10.12](#). Needle tracks may be visible in intravenous users and there may be drug-related paraphernalia. Methadone may also cause QT<sub>c</sub> prolongation and torsades de pointes. Features of opioid poisoning can be prolonged for up to 48 hours after use of long-acting agents such as methadone or oxycodone.

Use of the specific opioid antagonist naloxone (0.4–2 mg IV in an adult, repeated if necessary) may obviate the need for intubation, although excessive doses may precipitate acute withdrawal in chronic opiate users and breakthrough pain in those receiving opioids for pain management. Repeated doses or an infusion are often required because the half-life of the antidote is short compared to that of most opiates, especially those with prolonged elimination. Patients should be monitored for at least 6 hours after the last naloxone dose. Rare complications of naloxone therapy include fits, ventricular arrhythmias and pulmonary oedema.

### Gamma hydroxybutyrate

Gamma hydroxybutyrate (GHB), and the related compounds gamma butyrolactone (GBL), 1,4 butanediol, gamma-hydroxyvaleric acid (GHV) and gamma-valerolactone (GVL), are sedative substances with psychedelic and body-building effects. They are usually supplied as clear fluids and have been administered surreptitiously to enable drug-facilitated sexual assaults or other crimes.

As well as sedative hypnotic features (see [Box 10.12](#)), toxicity may cause nausea, diarrhoea, vertigo, tremor, myoclonus, extrapyramidal signs, euphoria, bradycardia, convulsions, metabolic acidosis, hypokalaemia and hyperglycaemia. Coma usually resolves abruptly within a few hours, but occasionally persists for several days. Dependence may develop in regular users, who experience severe, prolonged withdrawal effects if use is discontinued suddenly.

Management is largely supportive. All patients should be observed for a minimum of 2 hours and until symptoms resolve, with monitoring of blood pressure, heart rate, respiratory rate and oxygenation. Withdrawal symptoms may require treatment with very high doses of benzodiazepine.

### Stimulants and entactogens

These are sympathomimetic and serotonergic amines that have overlapping clinical features, depending on the balance of their stimulant (see [Box 10.12](#)) and serotonergic (see [Box 10.10](#)) effects. As well as traditional drugs such as cocaine, amphetamines and ecstasy, the group includes many more recently emerging new psychoactive substances, including cathinones (e.g. mephedrone), piperazines (e.g. benzylpiperazine), piperadines (e.g. ethylphenidate), benzofurans (e.g. 5-aminopropylbenzofuran) and NBOMe compounds (e.g. 25I-NBOMe).

### Cocaine

Cocaine is available as a water-soluble hydrochloride salt powder suitable for nasal inhalation ('snorting'), or as insoluble free-base ('crack' cocaine) 'rocks' that, unlike the hydrochloride salt, vaporise at high temperature and can be smoked, giving a more rapid and intense effect.

Effects appear rapidly after inhalation and especially after smoking. Sympathomimetic stimulant effects predominate (see [Box 10.12](#)). Serious complications usually occur within 3 hours of use and include coronary artery spasm, leading to myocardial ischaemia or infarction, hypotension and ventricular arrhythmias. Cocaine toxicity should be considered in younger adults presenting with ischaemic chest pain.

Hyperpyrexia, rhabdomyolysis, acute renal failure and disseminated intravascular coagulation may occur.

A 12-lead ECG and ECG monitoring should be undertaken. ST segment elevation may occur in the absence of myocardial infarction and troponin T estimations are the most sensitive and specific markers of myocardial damage. Benzodiazepines and intravenous nitrates are useful for managing patients with chest pain or hypertension. Acidosis should be corrected and physical cooling measures used for hyperpyrexia. Beta-blockers may be contraindicated because of the risk of unopposed  $\alpha$ -adrenoceptor stimulation, but this is debated. Coronary angiography should be considered in patients with myocardial infarction or acute coronary syndromes.

### Amphetamines and cathinones

Amphetamine-related compounds include amphetamine sulphate ('speed'), methylamphetamine ('crystal meth') and 3,4-methylenedioxymethamphetamine (MDMA, 'ecstasy'). Synthetic cathinones include mephedrone, methylenedioxypropylvalerone (MDPV) and n-ethyl pentylone. Tolerance is common, leading regular users to seek ever-higher doses.

Toxic features usually appear within a few minutes of use and last 4–6 hours, or substantially longer after a large overdose. Sympathomimetic stimulant and serotonergic effects are common (see [Boxes 10.10](#) and [10.12](#)). Some users develop hyponatraemia as a result of excessive water-drinking or inappropriate vasopressin (antidiuretic hormone, ADH) secretion. Muscle rigidity, pain and bruxism (clenching of the jaw), hyperpyrexia, rhabdomyolysis, metabolic acidosis, acute renal failure, disseminated intravascular coagulation, hepatocellular necrosis, acute respiratory distress syndrome (ARDS) and cardiovascular collapse have all been described following MDMA use. Cerebral infarction and haemorrhage have been reported, especially after intravenous amphetamine use.

Management is supportive and directed at complications (see [Box 10.8](#)).

### Hallucinogens

#### Cannabis

Derived from the dried leaves and flowers of *Cannabis sativa*, cannabis produces euphoria, perceptual alterations and conjunctival injection, followed by enhanced appetite, relaxation and occasionally hypertension, tachycardia, slurred speech and ataxia. Effects occur 10–30 minutes after smoking or 1–3 hours after ingestion, and last 4–8 hours. Solutions are also available for 'vaping' using electronic cigarettes. High doses of cannabis may produce anxiety, delirium, hallucinations and psychosis, but serious acute toxicity is uncommon and supportive treatment is all that is required. Psychological dependence is common, but tolerance and withdrawal symptoms are unusual. Long-term use is thought to increase the lifetime risk of psychosis and a cannabis hyperemesis syndrome is also recognised, involving episodes of vomiting that respond poorly to antiemetics, but improve on discontinuation of cannabis use.

#### Synthetic cannabinoid receptor agonists

Synthetic cannabinoid receptor agonists (SCRAs), sometimes referred to collectively as 'spice', have recently been in common use as legal alternatives to cannabis. More than 150 different SCRAs have been encountered, with recently prevalent examples including MDMB-CHMICA, 5F-MDMB-PINACA and AMB-FUBINACA. They are usually sprayed on to a herbal smoking mix and packaged as smoking products with appealing brand names. These may contain more than one SCRA and content may change with time. 'Vaping' of SCRA solutions has also been reported.

The toxic effects of SCRAs differ from those of cannabis, being generally more marked and including agitation, panic, delirium, hallucinations, tachycardia, ECG changes, hypertonia, dyspnoea and vomiting. Coma, respiratory acidosis, seizures, hypokalaemia and renal dysfunction may also occur. There is increasing evidence of pharmacological tolerance and dependence with SCRA use and features of withdrawal may occur after discontinuation. Treatment of intoxication is supportive.

## Tryptamines

These are predominantly 5-hydroxytryptamine (5-HT, serotonin; especially 5-HT<sub>2A</sub>) agonists with associated stimulant effects. Typical clinical features include hallucinations, agitation, delirium, hypertension, tachycardia, sweating, anxiety and headache. Serotonin syndrome may occur (see Box 10.10), especially if tryptamines are used in combination with other serotonergic agents. Naturally occurring examples are psilocin and psilocybin, found in 'magic mushrooms', and dimethyltryptamine (DMT) in traditional ayahuasca brews. Synthetic tryptamines, such as alpha-methyltryptamine (AMT), have also been encountered.

## D-Lysergic acid diethylamide

D-Lysergic acid diethylamide (LSD) is a synthetic ergoline usually ingested as small squares of impregnated absorbent paper (often printed with a distinctive design) or as 'microdots'. The drug causes perceptual effects, such as heightened visual awareness of colours or distortion of images. Hallucinations may be pleasurable or terrifying ('bad trip'). Other features are delirium, agitation, aggression, dilated pupils, hypertension, pyrexia and metabolic acidosis. Psychosis may sometimes last several days.

Patients with psychotic reactions or CNS depression should be observed in hospital, preferably in a quiet, dimly lit room to minimise external stimulation. A benzodiazepine can be used for sedation if required, avoiding antipsychotics if possible because these may precipitate cardiovascular collapse or convulsions.

## Dissociative drugs

Ketamine, its *N*-ethyl derivative methoxetamine and phencyclidine (now rarely encountered) produce a sense of dissociation from reality, often associated with visual and auditory distortions. Memory loss, impaired consciousness, agitation, hallucinations, tremors and numbness may also occur. Long-term ketamine or methoxetamine use can cause severe chronic cystitis with dysuria, frequency, urgency, haematuria and incontinence. These features are often severe, debilitating and difficult to treat. Management of acute intoxication is supportive.

## Volatile substances

Inhalation of volatile nitrites (e.g. amyl nitrite, isobutyl nitrite), often sold in bottles or vials as 'poppers', is reported to produce a feeling of pleasure and warmth, relax the anal sphincter and prolong orgasm. These potent vasodilators commonly provoke headache, dizziness, hypotension and tachycardia. They also oxidise haemoglobin to produce methaemoglobinemia, with resulting breathlessness and delirium. Severe methaemoglobinemia is treated with methylnthionium chloride ('methylene blue', see Fig. 10.1) Regular use may also precipitate maculopathy with visual loss.

Several volatile solvents found in household products, such as propane, butane, toluene and trichloroethylene, have a mild euphoriant effect if inhaled. Serious toxic effects can occur, including reduced level of consciousness, seizures and cardiac arrhythmias; there is also a risk of asphyxia from some methods of inhalation.

Nitrous oxide is an anaesthetic gas, but small canisters of it are sold for the domestic production of whipped cream and the contents of these can be transferred to balloons for inhalation. The gas has euphoriant effects ('laughing gas'), but hazards include asphyxia from inhalation without oxygen, or vitamin B<sub>12</sub> inactivation from chronic use leading to megaloblastic anaemia, psychosis and other neurological sequelae.

## Body packers and body stuffers

Body packers ('mules') attempt to smuggle illicit drugs (usually cocaine, heroin or amphetamines) by ingesting multiple small packages wrapped in several layers of clingfilm or in condoms. Body stuffers are those who have ingested unpackaged or poorly wrapped substances, often to avoid

**Fig. 10.4** Abdominal X-ray of a body packer showing multiple drug-filled condoms.

arrest. Both groups are at risk of severe toxicity if the packages rupture. This is more likely for body stuffers, who may develop symptoms of poisoning within 8 hours of ingestion. The risk of poisoning depends on the quality of the wrapping, and the amount and type of drug ingested. Cocaine, for example, presents a much higher risk than heroin because of its high toxicity and lack of a specific antidote.

Patients suspected of body packing or stuffing should be admitted for observation. A careful history taken in private is important, but for obvious reasons patients may withhold details of the drugs involved. Examination of the mouth, rectum and vagina as possible sites for concealed drugs should be arranged with patient consent, consistent with local laws. A urine toxicology screen performed at intervals may provide evidence of leakage, although positive results may reflect earlier drug use. Packages may be visible on plain abdominal films (Fig. 10.4), but ultrasound and computed tomography (CT) are more sensitive. One of these (preferably CT) should be performed in all suspected body packers.

Antimotility agents are often used by body packers to prevent premature passage of packages; it can take several days for packages to pass spontaneously, during which the carrier is at risk from package rupture. Whole bowel irrigation is commonly used to accelerate passage and is continued until all packages have passed. Surgery may be required when there is mechanical bowel obstruction or when evolving clinical features suggest package rupture, especially with cocaine.

## Chemicals and pesticides

### Carbon monoxide

Carbon monoxide (CO) is a colourless, odourless gas produced by faulty appliances burning organic fuels. It is also present in vehicle exhaust fumes and sometimes in smoke from house fires or barbecues. It binds with haemoglobin (to form carboxyhaemoglobin) and cytochrome oxidase, reducing tissue oxygen delivery and inhibiting cellular respiration. CO is a common cause of death by poisoning and most patients die before reaching hospital.

### Clinical features

Early features include headache, nausea, irritability, weakness and tachypnoea. The cause of these non-specific features may not be obvious if the exposure is occult, such as from a faulty domestic appliance. Subsequently, ataxia, nystagmus, drowsiness and hyper-reflexia may develop, progressing to coma, convulsions, hypotension, respiratory

depression, cardiovascular collapse and death. Myocardial ischaemia may result in arrhythmias or myocardial infarction. Cerebral oedema is common and rhabdomyolysis may cause myoglobinuria and renal failure. In those who recover from acute toxicity, longer-term neuropsychiatric effects are common, such as personality change, memory loss and concentration impairment. Extrapyramidal effects, urinary or faecal incontinence, and gait disturbance may also occur. Poisoning during pregnancy may cause fetal hypoxia and intrauterine death.

## Management

Patients should be removed from exposure as soon as possible and resuscitated as necessary. A high concentration of oxygen should be administered via a tightly fitting facemask; this reduces the half-life of carboxyhaemoglobin from 4–6 hours to about 40 minutes. Measurement of carboxyhaemoglobin is useful for confirming exposure; levels >20% suggest significant exposure, but do not correlate well with the severity of poisoning, partly because concentrations fall rapidly after removal of the patient from exposure, especially if supplemental oxygen has been given.

An ECG should be performed in all patients with acute CO poisoning, especially those with pre-existing heart disease. Arterial blood gas analysis should be checked in those with serious poisoning. Pulse oximetry may provide misleading oxygen saturation levels because the devices do not distinguish between carboxyhaemoglobin and oxyhaemoglobin. Excessive intravenous fluid administration should be avoided, particularly in the older patients, because of the risk of pulmonary and cerebral oedema. Convulsions should be controlled with diazepam.

Hyperbaric oxygen therapy is controversial. At 2.5 atmospheres, the half-life of carboxyhaemoglobin is reduced to about 20 minutes and the amount of oxygen dissolved in plasma is increased 10-fold, but systematic reviews have not consistently shown improved clinical outcomes. The logistical difficulties of transporting sick patients to hyperbaric chambers and managing them therein are substantial.

## Organophosphorus insecticides and nerve agents

Organophosphorus (OP) compounds (Box 10.13) have been widely used as pesticides, especially in low- and middle-income countries. Case fatality following deliberate ingestion is high (5%–20%). Legal controls banning the most toxic examples have substantially reduced local rates of suicide, for example in Sri Lanka.

Nerve agents, developed for chemical warfare, are derived from OP insecticides and are much more toxic. They are commonly classified as G (originally synthesised in Germany) or V ('venomous') agents. The 'G' agents, such as tabun, sarin and soman, are volatile, absorbed by inhalation or via the skin, and dissipate rapidly after use. 'V' agents, such as

10.13 Organophosphorus compounds	
<b>Nerve agents</b>	<ul style="list-style-type: none"> <li>• G agents: sarin, tabun, soman</li> <li>• V agents: VX, VE</li> <li>• Novichok agents</li> </ul>
<b>Insecticides</b>	
<b>Dimethyl compounds</b>	<ul style="list-style-type: none"> <li>• Dichlorvos</li> <li>• Fenthion</li> <li>• Malathion</li> <li>• Methamidophos</li> </ul>
<b>Diethyl compounds</b>	<ul style="list-style-type: none"> <li>• Chlorpyrifos</li> <li>• Diazinon</li> <li>• Parathion-ethyl</li> <li>• Quinalphos</li> </ul>

VX, are contact poisons unless aerosolised and contaminate ground for weeks or months. Novichok agents, originally developed in the former Soviet Union, have also recently been encountered.

The toxicology and management of nerve agent and pesticide poisoning are similar.

## Mechanism of toxicity

OP compounds inactivate acetylcholinesterase (AChE), resulting in the accumulation of acetylcholine (ACh) in cholinergic synapses (Fig. 10.5). Initially, spontaneous hydrolysis of the OP–enzyme complex allows reactivation of the enzyme but, subsequently, loss of a chemical group from the OP–enzyme complex prevents further enzyme reactivation. After this process (termed 'ageing') has taken place, new enzyme needs to be synthesised before function can be restored. The rate of 'ageing' is an important determinant of toxicity and is more rapid with dimethyl (3.7 hours) than diethyl (31 hours) compounds (see Box 10.13) and especially rapid after exposure to nerve agents (soman in particular), which cause 'ageing' within minutes.

## Clinical features and management

OP poisoning causes an acute cholinergic phase, which may occasionally be followed by the 'intermediate syndrome' and organophosphate-induced delayed polyneuropathy (OPIDN). The onset, severity and duration depend on the route of exposure and agent involved.

### Acute cholinergic syndrome

This usually starts within a few minutes of exposure and nicotinic or muscarinic features may be present (Box 10.14). Vomiting and profuse diarrhoea are typical following ingestion. Bronchoconstriction, bronchorrhoea and salivation may cause severe respiratory compromise. Excess sweating and miosis are characteristic and the presence of muscular fasciculations strongly suggests the diagnosis, although this feature is often absent, even in serious poisoning. Subsequently, generalised flaccid paralysis may develop and affect respiratory and ocular muscles,

Fig. 10.5 Mechanism of toxicity of organophosphorus compounds and treatment with oxime.

## 10.14 Cholinergic features in poisoning\*

	Muscarinic	Nicotinic
<b>Respiratory</b>	Bronchorrhoea, bronchoconstriction	Reduced ventilation
<b>Circulation</b>	Bradycardia, hypotension	Tachycardia, hypertension
<b>Higher mental function</b>	Anxiety, delirium, psychosis	
<b>Muscle</b>	–	Fasciculation, paralysis
<b>Temperature</b>	Fever	–
<b>Eyes</b>	Diplopia, miosis, lacrimation	Mydriasis
<b>Abdomen</b>	Vomiting, profuse diarrhoea	–
<b>Mouth</b>	Salivation	–
<b>Skin</b>	Sweating	–
<b>Complications</b>	Coma, seizures, respiratory depression	

\*Both muscarinic and nicotinic features occur in OP poisoning. Nicotinic features occur in nicotine poisoning and Black Widow spider bites. Cholinergic features are sometimes seen with some mushrooms.

resulting in respiratory failure. Ataxia, coma, convulsions, cardiac repolarisation abnormalities and torsades de pointes may occur.

### Management

The airway should be cleared of excessive secretions, breathing and circulation assessed, high-flow oxygen administered and intravenous access obtained. Appropriate external decontamination is needed (p. 221). Gastric lavage or activated charcoal may be considered if the patient presents sufficiently early. Seizures should be treated as described in Box 10.8. The ECG, oxygen saturation, blood gases, temperature, urea and electrolytes, amylase and glucose should be monitored closely.

Early use of sufficient doses of atropine is potentially life-saving in patients with severe toxicity. Atropine reverses ACh-induced bronchospasm, bronchorrhoea, bradycardia and hypotension. When the diagnosis is uncertain, a marked increase in heart rate associated with skin flushing after a 1 mg intravenous dose makes OP poisoning unlikely. In OP poisoning, atropine (2 mg IV) should be administered and this dose should be doubled every 5–10 minutes until clinical improvement occurs. Further bolus doses should be given until secretions are controlled, the skin is dry, blood pressure is adequate and heart rate is >80 bpm. Large doses may be needed, but excessive doses may cause anticholinergic effects (see Box 10.10).

In severe poisoning requiring atropine, an oxime (such as pralidoxime chloride or obidoxime) is generally recommended if available, although efficacy is debated. This may reverse or prevent muscle weakness, convulsions or coma, especially if given rapidly after exposure. Oximes reactivate AChE that has not undergone 'ageing' and are therefore less effective with dimethyl compounds and nerve agents, especially soman. Oximes may provoke hypotension, especially if administered rapidly.

Intravenous magnesium sulphate has been reported to increase survival in animals and in small human studies of OP poisoning; however, further clinical trial evidence is needed before this can be recommended routinely.

Ventilatory support should be instituted before the patient develops respiratory failure. Benzodiazepines may be used to treat agitation, fasciculations and seizures and for sedation during mechanical ventilation.

Exposure is confirmed by measurement of plasma or red blood cell cholinesterase activity, but antidote use should not be delayed pending results. Plasma cholinesterase is reduced more rapidly, but is less specific than red cell cholinesterase. Values correlate poorly with the severity of clinical features, but are usually <10% in severe poisoning, 20%–50% in moderate poisoning and >50% in subclinical poisoning.

The acute cholinergic phase usually lasts 48–72 hours, with most patients requiring intensive cardiorespiratory support and monitoring. Cholinergic features may be prolonged over several weeks with some lipid-soluble agents.

### Intermediate syndrome

About 20% of patients with OP poisoning develop weakness that spreads rapidly from the ocular muscles to those of the head and neck, proximal limbs and the muscles of respiration, resulting in ventilatory failure. This 'intermediate syndrome' generally develops 1–4 days after exposure, often after resolution of the acute cholinergic syndrome and may last 2–3 weeks. There is no specific treatment and supportive care is needed, including maintenance of airway and ventilation.

### Organophosphate-induced delayed polyneuropathy

Organophosphate-induced delayed polyneuropathy (OPIDN) is a rare complication that usually occurs 2–3 weeks after acute exposure. It is a mixed sensory/motor polyneuropathy, affecting long myelinated neurons especially, and appears to result from inhibition of enzymes other than AChE. It is a feature of poisoning with some OPs such as triorthocresyl phosphate, but is less common with nerve agents. Early clinical features are muscle cramps followed by numbness and paraesthesiae, proceeding to flaccid paralysis of the lower and subsequently the upper limbs, with foot and wrist drop and a high-stepping gait, progressing to paraplegia. Sensory loss may also be present but is variable. Initially, tendon reflexes are reduced or lost but mild spasticity may develop later.

There is no specific therapy for OPIDN. Regular physiotherapy may limit deformity caused by muscle wasting. Recovery is often incomplete and may be limited to the hands and feet, although substantial functional recovery after 1–2 years may occur, especially in younger patients.

## Carbamate insecticides

Carbamate insecticides such as bendiocarb, carbofuran, carbaryl and methomyl inhibit a number of tissue esterases, including AChE. The mechanism, clinical features and management of toxicity are similar to those of OP compounds. However, clinical features are usually less severe and of shorter duration, because the carbamate–AChE complex dissociates quickly, with a half-life of 30–40 minutes, and does not undergo ageing. Also, carbamates penetrate the CNS poorly. Intermediate syndrome and OPIDN are not common features of carbamate poisoning. In spite of this, case fatality can be high for some carbamates, depending on their formulation.

Atropine may be given intravenously as for OP poisoning (see above, this section) is unnecessary.

## Paraquat

Paraquat is a herbicide that has been widely used across the world, although it has been banned in the European Union and some other countries for many years. It is highly toxic if ingested, with clinical features including oral burns, vomiting and diarrhoea, progressing to pneumonitis, pulmonary fibrosis and multi-organ failure.

Exposure can be confirmed by a urinary dithionite test, while the plasma paraquat concentration gives an indication of prognosis. There is no specific antidote, but activated charcoal is commonly administered. Immunosuppression with glucocorticoids and cyclophosphamide is sometimes used, but evidence for benefit is weak. Irrespective of treatment, death is common and may occur within 24 hours with substantial poisoning or after 1–2 weeks with lower doses.

## Alcohols and glycols

Ethanol (alcohol, ethyl alcohol) is commonly consumed in alcoholic beverages but is also found in some cosmetics, perfumes and antiseptic hand gels. It may also be used as an industrial solvent or produced illicitly. It can also be used as an antidote in ethylene glycol or methanol

poisoning (see below). The health effects of chronic alcohol use are described in [Chapter 31](#).

Acute alcohol consumption causes concentration-related toxicity, although it is unusual for ethanol toxicity alone to precipitate hospital admission. Severe and fatal toxicity, however, is more likely in children or when alcohol has been used with other sedative substances such as opioids or benzodiazepines. High concentrations of alcohol produce incoordination and slurred speech, and this may progress to unconsciousness with respiratory depression, loss of airway reflexes, hypotension, metabolic acidosis and occasionally hypothermia, hypoglycaemia and convulsions. Investigations should include measurement of blood alcohol concentration, arterial blood gases as well as full blood count, glucose, renal and hepatic function. Management involves protection of the airway, maintenance of ventilation and oxygenation, fluid resuscitation, correction of hypoglycaemia with glucose and treatment of convulsions. Thiamine should be administered if chronic excess alcohol use is suspected. Haemodialysis is effective for increasing alcohol clearance and should be considered in severe cases associated with very high ethanol concentrations.

Ethylene glycol (1,2-ethanediol) is found in antifreeze, brake fluids and, in lower concentrations, windscreen washes. Methanol is present in some antifreeze products and commercially available industrial solvents, and in low concentrations in some screen washes and methylated spirits. It may also be an adulterant of illicitly produced alcohol. Both are rapidly absorbed after ingestion. Methanol and ethylene glycol are not of high intrinsic toxicity, but are converted via alcohol dehydrogenase to toxic metabolites that are largely responsible for their clinical effects ([Fig. 10.6](#)).

Early features of poisoning with either methanol or ethylene glycol include vomiting, ataxia, drowsiness, dysarthria and nystagmus. As toxic metabolites are formed, metabolic acidosis, tachypnoea, coma and seizures may develop.

Toxic effects of ethylene glycol include ophthalmoplegia, cranial nerve palsies, hyporeflexia and myoclonus. Renal pain and acute tubular necrosis occur because of renal calcium oxalate precipitation. Hypocalcaemia, hypomagnesaemia and hyperkalaemia are common.

Methanol poisoning causes headache, delirium and vertigo. Visual impairment and photophobia develop, associated with optic disc and retinal oedema and impaired pupil reflexes. Blindness may be permanent, although some recovery may occur over several months. Pancreatitis and abnormal liver function have also been reported.

Urea and electrolytes, chloride, bicarbonate, glucose, calcium, magnesium, albumin, plasma osmolarity and arterial blood gases should be measured in all patients with suspected methanol or ethylene glycol toxicity. The osmolar and anion gaps should be calculated (see [Box 10.5](#)).

**Fig. 10.6** Metabolism of methanol and ethylene glycol.

Initially, poisoning is associated with an increased osmolar gap, but as toxic metabolites are produced an increased anion gap develops associated with metabolic acidosis. The diagnosis can be confirmed by measurement of ethylene glycol or methanol concentrations, but assays are not widely available.

An antidote, ideally fomepizole or otherwise ethanol, should be administered to all patients with suspected significant exposure while awaiting the results of laboratory investigations. These block alcohol dehydrogenase and delay the formation of toxic metabolites until the parent drug is eliminated in the urine or by dialysis. The antidote should be continued until ethylene glycol or methanol concentrations are undetectable. Metabolic acidosis should be corrected with sodium bicarbonate (e.g. 250 mL of 1.26% solution, repeated as necessary). Convulsions should be treated with an intravenous benzodiazepine. In ethylene glycol poisoning, hypocalcaemia should be corrected only if there are severe ECG features or if seizures occur, as this may increase calcium oxalate crystal formation. In methanol poisoning, folinic acid should be administered to enhance the metabolism of the toxic metabolite, formic acid.

Haemodialysis or haemodiafiltration should be used in severe poisoning, especially if renal failure is present or there is visual loss in the context of methanol poisoning. It should be continued until acute toxic features are no longer present and ethylene glycol/methanol concentrations are undetectable.

## Corrosive substances

Products containing acids (e.g. hydrochloric or sulphuric acid) or alkalis (e.g. sodium hydroxide, calcium carbonate) may be ingested accidentally or intentionally, causing gastrointestinal pain, ulceration and necrosis, with risk of perforation. Severity depends on the volume and pH of the substance ingested.

External decontamination (p. 221), if needed, should be performed after initial resuscitation. Gastric lavage should not be attempted and neutralising chemicals should not be administered after large ingestions because of the risk of tissue damage from heat release. Cardiorespiratory monitoring is necessary and full blood count, renal function, coagulation and acid–base status should be assessed. An erect chest X-ray should be performed if perforation is suspected and may show features of mediastinitis or gas under the diaphragm. Strong analgesics should be administered for pain.

Severe abdominal or chest pain, abdominal distension, shock or acidosis may indicate perforation and should prompt an urgent CT scan of chest and abdomen and surgical review. In the absence of perforation, drooling, dysphagia, stridor or oropharyngeal burns suggest possible severe oesophageal damage and early endoscopy by an experienced operator should be considered. Delayed endoscopy (e.g. after several days) may carry a higher risk of perforation.

## Aluminium and zinc phosphide

These rodenticides and fumigants are a common means of self-poisoning in northern India. The mortality rate for aluminium phosphide ingestion has been estimated at 60%; zinc phosphide ingestion appears less toxic (mortality about 2%). When ingested, both compounds react with gastric acid to form phosphine, a potent pulmonary and gastrointestinal toxicant. Clinical features include severe gastrointestinal disturbances, chest tightness, cough and breathlessness progressing to ARDS and respiratory failure, tremor, paraesthesiae, convulsions, coma, tachycardia, metabolic acidosis, electrolyte disturbances, hypoglycaemia, myocarditis, liver and renal failure, and leucopenia. Ingestion of a few tablets can be fatal.

Treatment is supportive and directed at correcting electrolyte abnormalities and treating complications; there is no specific antidote. Early gastric lavage is sometimes used, often with vegetable oil to reduce the release of toxic phosphine, but the benefit is uncertain.

## Copper sulphate

This is used as a fungicide. If ingested, clinical features of toxicity include nausea, vomiting, abdominal pain, diarrhoea, discoloured (blue/green) secretions, corrosive effects on the gastrointestinal tract, renal or liver failure, methaemoglobinaemia, haemolysis, rhabdomyolysis, convulsions and coma. Treatment is as for other corrosive substances (see above) and should address complications, including use of methylthioninium chloride for methaemoglobinaemia (see Fig. 10.1). Chelation therapy is unlikely to be beneficial after acute exposure.

## Chemicals less commonly taken in poisoning

An overview of the clinical features and management for chemicals less commonly involved in poisoning is provided in Box 10.15.

## Chemical warfare agents

Some toxins have been developed for use as chemical warfare agents. These are summarised in Box 10.16.

### i

#### 10.15 Clinical features and specific management of chemicals less commonly involved in poisoning

Substance	Clinical features	Management
<b>Lead</b> e.g. chronic occupational exposure, leaded paint, water contaminated by lead pipes, use of kohl cosmetics	Abdominal pain Microcytic anaemia with basophilic stippling Headache and encephalopathy Motor neuropathy Nephrotoxicity Hypertension Hypocalcaemia	Prevention of further exposure Measurement of blood lead concentration, full blood count and blood film, urea and electrolytes, liver function tests and calcium Abdominal X-ray in children to detect pica Bone X-ray for 'lead lines' Chelation therapy with DMSA or sodium calcium edetate
<b>Barium salts</b>	GI upset, haematemesis, hypersalivation, perioral paraesthesia, Cyanosis, bradycardia, chest pain, breathlessness. Profound hypokalaemia	Abdominal X-ray to confirm ingestion of radio-opaque material. Aggressive correction of hypokalaemia Haemodialysis in severe cases (removes barium and may correct hypokalaemia)
<b>Strychnine</b>	Rapid onset of gastrointestinal symptoms Agitation, sweating, tachycardia, chest pain, Muscular stiffness and twitching, convulsions and respiratory arrest.	Supportive care including treatment of agitation and convulsions
<b>Thallium</b>	Gastrointestinal disturbances including bleeding Subsequently pancreatitis, parotid swelling, confusion, peripheral neuropathy, alopecia, renal, liver, cardiac or bone marrow failure Coma and death developing over 7–21 days.	Oral Prussian blue or repeated doses of activated charcoal (adsorb thallium in the gut). Supportive care including treatment of convulsions and cardiac complications
<b>Petroleum distillates</b> e.g. white spirit, kerosene	Vomiting Aspiration pneumonitis	Gastric lavage contraindicated Activated charcoal ineffective Oxygen and nebulised bronchodilators Chest X-ray to assess pulmonary effects
<b>Organochlorines</b> e.g. DDT, lindane, dieldrin, endosulfan	Nausea, vomiting Agitation Fasciculation Paraesthesiae (face, extremities) Convulsions Coma Respiratory depression Cardiac arrhythmias Hyperthermia Rhabdomyolysis Pulmonary oedema Disseminated intravascular coagulation	Activated charcoal (with nasogastric aspiration for liquid preparations) within 1 hr of ingestion Cardiac monitoring
<b>Pyrethroid insecticides</b> e.g. cypermethrin, permethrin, imiprothrin	Skin contact: dermatitis, skin paraesthesiae. Systemic features may occur after substantial exposure Eye contact: lacrimation, photophobia and oedema of the eyelids Inhalation: dyspnoea, nausea, headaches Ingestion: epigastric pain, nausea, vomiting, hypersalivation, headache, coma, convulsions, pulmonary oedema	Symptomatic and supportive care Washing contaminated skin makes irritation worse Hyoscine (20 mg subcutaneously every 4 hrs) may be useful for severe hypersalivation
<b>Anticoagulant rodenticides</b> e.g. brodifacoum, bromadiolone and warfarin	Abnormal bleeding (prolonged)	Monitor INR/prothrombin time Vitamin K <sub>1</sub> by slow IV injection if there is coagulopathy Fresh frozen plasma or specific clotting factors for bleeding

(DMSA = dimercaptosuccinic acid; INR = International Normalised Ratio; IV = intravenous)

10.16 Chemical warfare agents		
Examples	Clinical effects	Antidotes*
<b>Nerve agents</b>		
Tabun Sarin Soman VX Novichok agents	Eyes: miosis (sometimes painful) GI tract: diarrhoea, vomiting, salivation Respiratory: bronchoconstriction, respiratory paralysis/failure Neurological: fasciculations, tremor, ataxia, convulsions, flaccid muscular paralysis See also p. 232 and Box 10.13	Atropine Oximes (e.g. pralidoxime, obidoxime) (see Fig. 10.5)
<b>Blistering agents</b>		
Nitrogen/sulphur Mustard Lewisite	Eyes: watering, blepharospasm, corneal ulceration Skin: erythema, blistering Respiratory: cough, hoarseness, dyspnoea, pneumonitis	None
<b>Choking agents</b>		
Chlorine Phosgene	Eyes: watering, blepharospasm, corneal ulceration Respiratory: cough, hoarseness, dyspnoea, pneumonitis	None
<b>Blood agents</b>		
Cyanide	Cardiovascular: dizziness, shock Respiratory: dyspnoea, cyanosis CNS: anxiety, headache, delirium, convulsions, coma, fixed dilated pupils Other: vomiting, lactic acidosis	Dicobalt edetate Hydroxocobalamin Sodium nitrite Sodium thiosulphate
*Appropriate resuscitation, decontamination and supportive care are essential after exposure to all chemical warfare agents. Use appropriate personal protective equipment.		

## Environmental poisoning

### Arsenism

Chronic arsenic exposure from drinking water has been reported in many countries, especially India, Bangladesh, Nepal, Thailand, Taiwan, China, Mexico and South America, where a large proportion of the drinking water (ground water) has a high arsenic content, placing large populations at risk. The World Health Organization (WHO) guideline value for arsenic content in tube well water is 10 µg/L.

Health effects associated with chronic exposure to arsenic in drinking water are shown in Box 10.17. In exposed individuals, high concentrations of arsenic are present in bone, hair and nails. Specific treatments are of no benefit in chronic arsenic toxicity and recovery from the peripheral neuropathy may never be complete, so the emphasis should be on prevention.

### Fluorosis

Fluoride poisoning can result from exposure to excessive quantities of fluoride (>10 ppm) in drinking water, industrial exposure to fluoride dust or consumption of brick teas. Clinical features include yellow staining

10.17 Clinical features of chronic arsenic poisoning	
<b>Gastrointestinal tract</b>	
<ul style="list-style-type: none"> <li>Anorexia, vomiting, weight loss, diarrhoea, increased salivation, metallic taste</li> </ul>	
<b>Neurological</b>	
<ul style="list-style-type: none"> <li>Peripheral neuropathy (sensory and motor) with muscle wasting and fasciculation, ataxia</li> </ul>	
<b>Skin</b>	
<ul style="list-style-type: none"> <li>Hyperpigmentation, palmar and plantar keratosis, alopecia, multiple epitheliomas, Mee's lines (transverse white lines on fingernails)</li> </ul>	
<b>Eyes</b>	
<ul style="list-style-type: none"> <li>Conjunctivitis, corneal necrosis and ulceration</li> </ul>	
<b>Bone marrow</b>	
<ul style="list-style-type: none"> <li>Aplastic anaemia</li> </ul>	
<b>Other</b>	
<ul style="list-style-type: none"> <li>Low-grade fever, vasospasm and gangrene, jaundice, hepatomegaly, splenomegaly</li> </ul>	
<b>Increased risk of malignancy</b>	
<ul style="list-style-type: none"> <li>Lung, liver, bladder, kidney, larynx and lymphoid system</li> </ul>	

and pitting of permanent teeth, osteosclerosis, soft tissue calcification, deformities (e.g. kyphosis) and joint ankylosis. Changes in the bones of the thoracic cage may lead to rigidity that causes dyspnoea on exertion. Very high doses of fluoride may cause abdominal pain, nausea, vomiting, seizures and muscle spasm. In calcium-deficient children, the toxic effects of fluoride manifest even at marginally high exposures to fluoride.

In endemic areas, such as Jordan, Turkey, Chile, India, Bangladesh, China and Tibet, fluorosis is a major public health problem, especially in communities engaged in physically strenuous agricultural or industrial activities. Dental fluorosis is endemic in East Africa and some West African countries.

## Food-related poisoning

### Paralytic shellfish poisoning

Paralytic shellfish poisoning is caused by consumption of bivalve molluscs (e.g. mussels, clams, oysters, cockles and scallops) contaminated with saxitoxins, which are concentrated in the shellfish as a result of constant filtration of toxic algae during algal blooms (e.g. 'red tide'). Symptoms develop within 10–120 minutes of eating the contaminated shellfish and include gastrointestinal disturbances, paraesthesia around the mouth or in the extremities, ataxia, mental state changes and dysphagia. In severe cases, paralysis and respiratory failure can develop. There is no specific antidote and treatment is supportive. Most cases resolve over a few days.

### Ciguatera poisoning

Ciguatera toxin and related toxins are produced by dinoflagellate plankton that adhere to algae and seaweed. These accumulate in the tropical herbivorous fish that feed on these and in their larger predators (e.g. snapper, barracuda), especially in the Pacific and Caribbean. Human exposure occurs through eating contaminated fish, even if well cooked. Nausea, vomiting, diarrhoea and abdominal pain develop within a few hours, followed by paraesthesia, ataxia, blurred vision, ataxia and tremor. Convulsions and coma can occur, although death is uncommon. Fatigue and peripheral neuropathy can be long-term effects. There is no specific treatment. In the South Pacific and Caribbean, there are approximately 50 000 cases per year, with a case fatality of 0.1%.

## 10.18 Some poisonous plants and fungi, with their clinical effects

Species (common name)	Toxins	Important features of toxicity
<b>Plants</b>		
<i>Abrus precatorius</i> (jequirity bean)	Abrin	Gastrointestinal effects, drowsiness, delirium, convulsions, multi-organ failure
<i>Ricinus communis</i> (castor oil plant)	Ricin	
<i>Aconitum napellus</i> (aconite, wolf's bane, monkshood)	Aconite	Gastrointestinal effects, paraesthesiae, convulsions, ventricular tachycardia
<i>Aconitum ferox</i> (Indian aconite, bikh)		
<i>Atropa belladonna</i> (deadly nightshade)	Atropine,	Anticholinergic toxidrome (see <a href="#">Box 10.10</a> )
<i>Datura stramonium</i> (Jimson weed, thorn apple)	scopolamine,	
<i>Brugmansia</i> spp. (angel's trumpet)	hyocymine	
<i>Colchicum autumnale</i> (autumn crocus)	Colchicine	Gastrointestinal effects, hypotension, cardiogenic shock
<i>Conium maculatum</i> (hemlock)	Toxic nicotinic alkaloids	Hypersalivation, gastrointestinal effects, followed by muscular paralysis
<i>Digitalis purpurea</i> (foxglove)	Cardiac glycosides	Nausea, vomiting, bradycardia and heart block, supraventricular and ventricular tachyarrhythmias, visual disturbances, confusion (p. 224)
<i>Nerium oleander</i> (pink oleander)		
<i>Thevetia peruviana</i> (yellow oleander)		
<i>Laburnum anagyroides</i> (laburnum)	Cytosine	Gastrointestinal effects; convulsions in severe cases
<i>Taxus baccata</i> (yew)	Taxane alkaloids	Hypotension, bradycardia, respiratory depression, convulsions, coma, arrhythmias
<b>Fungi</b>		
<i>Amanita phalloides</i> (death cap mushroom)	Amatoxins	Gastrointestinal effects, progressing to liver failure
<i>Cortinarius</i> spp.	Orellanine	Gastrointestinal effects, fever, progressing to renal failure
<i>Psilocybe semilanceata</i> ('magic mushrooms')	Psilocybin, psilocin	Hallucinations

### Scombrototoxic fish poisoning

Under poor storage conditions, histidine in scombroid fish (e.g. tuna, mackerel, bonito, skipjack and the dark meat of canned sardines) may be converted by bacteria to histamine and other chemicals. Within minutes of consumption, flushing, burning, sweating, urticaria, pruritus, headache, colic, nausea and vomiting, diarrhoea, bronchospasm and hypotension may occur. Management is with nebulised salbutamol, intravenous antihistamines and, occasionally, intravenous fluid replacement.

### Tetrodotoxin poisoning

The highly toxic tetrodotoxin is found in the skin and viscera of Puffer fish. Tetrodotoxin blocks voltage-gated sodium channels, inhibiting action potential generation and propagation. Clinical features include paraesthesiae, salivation, gastrointestinal disturbances, sweating, headache, tachycardia, hypokalaemia, twitching or tremor, vertigo, dysphonia and dysphagia. In severe cases ataxia, paralysis and fixed dilated pupils occur, mimicking brain death. Without appropriate ventilator support, respiratory paralysis can be fatal. Otherwise there is no specific treatment and management is supportive.

### Plant poisoning

A substantial number of plants and fungi are potentially toxic if consumed, with patterns of poisoning depending on their geographical distribution. Some toxic examples and the clinical features of toxicity are shown in [Box 10.18](#).

## Multiple Choice Questions

10.1. Multiple doses of activated charcoal are useful in the treatment of patients with poisoning involving which one of the following:

- A. Ferrous sulphate
- B. Yellow oleander (*Thevetia peruviana*)
- C. Pesticides
- D. Lithium carbonate
- E. Dapsone

Answer: E.

Ferrous sulphate and lithium are not adsorbed by activated charcoal. A clinical trial of multiple-dose activated charcoal for patients with yellow oleander or pesticide poisoning showed no benefit. The clearance of dapsone is enhanced by multiple-dose activated charcoal. This is also true for carbamazepine, phenobarbital, quinine and theophylline (Box 10.7).

10.2. A 2-year-old child is assessed because the parents are concerned he has swallowed some aspirin tablets. Which one of the following clinical features is NOT consistent with a diagnosis of salicylate poisoning in a child?

- A. Respiratory alkalosis
- B. Metabolic alkalosis
- C. Hypoprothrombinaemia
- D. Hypothermia
- E. Hypotension

Answer: D.

Respiratory alkalosis is a common feature of salicylate poisoning, especially in children. Metabolic acidosis can also occur and is associated with a worse prognosis. Hypoprothrombinaemia is typical of salicylate poisoning. Shock, including hypotension, and hyperpyrexia may also be seen in severe poisoning. Hypothermia is not a feature of salicylate toxicity.

10.3. An adult male is found unconscious after a suspected drug overdose. ECG findings are as follows: heart rate 78/min, PR interval 162 ms, QRS interval 162 ms and QT interval 363 ms. The corrected QT interval (QTc, using Bazett's formula) is 414 ms. Which ONE of the following statements is correct?

- A. Severe cardiac potassium channel blockade is present
- B. Conduction velocity is increased in the bundles of His
- C. First-degree heart block is present
- D. Overdose with flecainide could account for the ECG findings
- E. Magnesium sulphate should be administered urgently

Answer: D.

The only abnormality identified is prolongation of the QRS interval, which is a feature caused by severe sodium channel blockade. This results in delayed phase 0 depolarisation and reduced conduction velocity in the bundles of His and in ventricular myocytes. Drugs that cause sodium channel blockade in overdose include class 1a (e.g. quinidine) and 1c (e.g. flecainide) anti-dysrhythmic drugs, tricyclic antidepressants, some  $\beta$ -blockers (e.g. propranolol), cocaine and diphenhydramine (Box 10.8). Cardiac sodium channel blockade is associated with an increased risk of monomorphic ventricular tachycardia and ventricular fibrillation. Treatment is with intravenous sodium bicarbonate. Potassium blockade is indicated by QTc prolongation and may culminate in torsades de pointes ventricular tachycardia, which is treated with magnesium sulphate; in this case, however, the QTc interval is normal, as is the PR interval, so first-degree heart block is also not present.

10.4. A homeless man aged 23 is found unconscious in the street after smoking an unidentified illicit drug. No further history is available. On examination his Glasgow Coma Scale (GCS) is 9, pupils are mid-sized and equal, heart rate is 110/min, blood pressure is 116/84 mmHg, and temperature is 36.8°C. Arterial blood gases show a mild respiratory acidosis. General physical examination is otherwise normal. No needle marks are found. Which of the following is the most likely substance causing this presentation?

- A. Heroin
- B. AMB-FUBINACA
- C. Alprazolam
- D. Ecstasy
- E. Gamma hydroxybutyrate

Answer: B.

Ecstasy does not cause a reduction in level of consciousness, but this can be caused by any of the other four drugs listed. Alprazolam (a benzodiazepine) and gamma hydroxybutyrate (GHB) could both cause this clinical presentation but are not used by smoking. Heroin can be smoked ('chasing the dragon') but would usually cause small pupils. AMB-FUBINACA is a synthetic cannabinoid receptor agonist. These compounds, commonly referred to as 'spice', are usually smoked; they can cause reduced level of consciousness and respiratory acidosis, without pupillary changes.

10.5. Which of the following antidotes does NOT act by binding to the toxin it is used to treat?

- A. Fomepizole
- B. Digoxin-specific antibody fragments
- C. Idarucizumab
- D. Hydroxocobalamin
- E. Desferrioxamine

Answer: A.

Fomepizole is an alcohol dehydrogenase inhibitor. It prevents the metabolism of ethylene glycol and methanol to the toxic metabolites responsible for the clinical features of poisoning. Digoxin-specific antibody fragments bind to digoxin (and other cardiac glycosides) and idarucizumab is a monoclonal antibody that binds to dabigatran etexilate. Hydroxocobalamin complexes with cyanide to form cyanocobalamin and desferrioxamine complexes with iron to form ferrioxamine. In all four of these examples, drug bound to the antidote no longer causes toxicity.

# Comprehensive evaluation of the evenomed patient

**1 Airway, breathing, circulation**

- Blood pressure
- Pulse
- Respiration rate
- Oxygen saturation
- Dysrhythmias

**2 Level of consciousness**

- Confusion
- Agitation
- Seizures

**3 Mouth, gums**

- Evidence of bleeding
- Increased salivation
- Drooling

**4 Cranial nerves**

- Drooling
- Dysarthria
- Dysphagia
- Upper airway compromise

▲ Bilateral mild ptosis

▲ Ptosis and lateral ophthalmoplegia

▲ Fixed dilated pupils

**5 Chest**

- Pulmonary oedema
- Diminished respiration

**12 Eyes**

- Miosis or mydriasis
- Increased lacrimation
- Corneal injury (venom spit injury)

▲ Chemosis – can indicate capillary leak syndrome

**11 Skin**

- In addition to (6):
- Piloerection
- Erythema
- Blistering
- Infection

▲ Local increased sweating

**10 Abdomen**

- Intra-abdominal, retroperitoneal or renal pathology

**9 Lymph nodes**

- Tender or enlarged nodes draining bite/sting area

**8 Muscles**

- Weakness
- Tenderness
- Pain

**7 Reflexes**

- Decreased or absent reflexes

**6 Bite/sting site**

- Pain
- Swelling
- Bruising
- Discoloration
- Necrosis

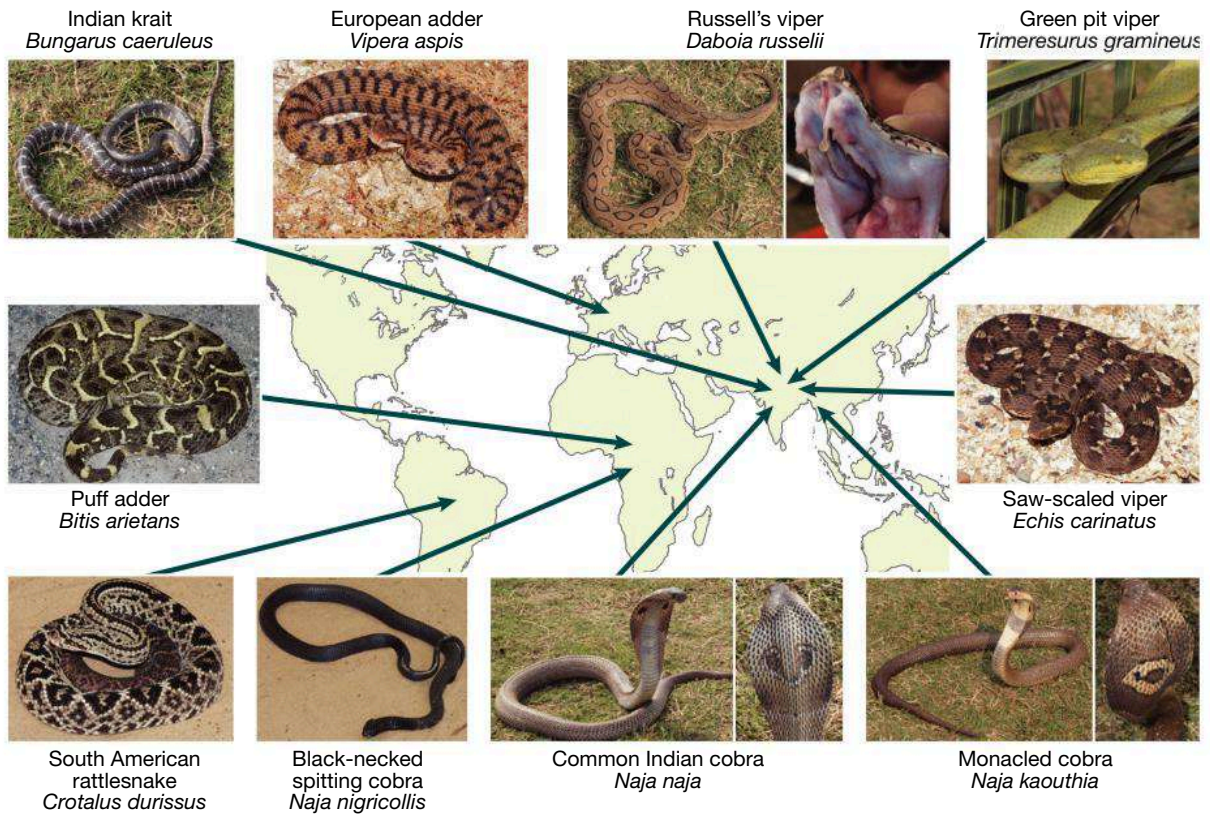

▲ Local bleeding, blistering

▲ Local bleeding

## Geographical distribution of venomous snakes

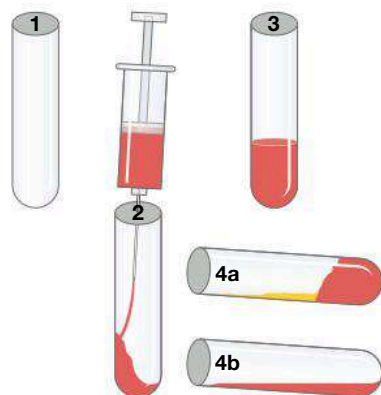

The geographical location of a snakebite determines the likely animal(s) involved and the nature and risks of the envenomation. Copyright © Julian White.

## Bedside tests in the envenomed patient

Examination of urine. Haematuria may indicate a coagulopathy. Dark urine is suggestive of myoglobinuria, which is a sign of extensive rhabdomyolysis. Copyright © Julian White.

- 1 Obtain a clean **glass** container (test tube or bottle) that is either new, or has only been washed with water (not detergent/soap)
- 2 Place 2–3 mL venous blood in the **glass** container
- 3 Allow to stand undisturbed for 20 mins
- 4 Gently invert/tip the glass container checking for presence of a blood clot
- 4a Clot present = negative test (no coagulopathy present)
- 4b Clot absent = positive test (coagulopathy present)

Twenty-minute whole-blood clotting test (20WBCT). The presence of coagulopathy is a key indicator of major envenoming for some species. While full laboratory coagulation studies may be the ideal, the 20WBCT has emerged as a simple standardised bedside test of coagulopathy, applicable even in areas with limited health facilities. Copyright © Julian White.

## Overview of envenomation

Envenomation occurs when a venomous animal injects sufficient venom by a bite or a sting into a prey item or perceived predator to cause deleterious local and/or systemic effects. This is defined as a venom-induced disease (VID). Venomous animals generally use their venom to acquire and, in some cases, pre-digest prey, with defensive use a secondary function for many species. Where defensive use of venom is an important evolutionary driver, immediate and severe local pain is a common feature, though the toxin mechanisms causing pain are diverse. Accidental encounters between venomous animals and humans are frequent, particularly in the rural tropics, where millions of cases of venomous bites and stings occur annually. Globally, an increasing number of exotic venomous animals are kept privately, so cases of envenoming may present to hospitals where doctors have insufficient knowledge to manage potentially complex presentations. Doctors everywhere should thus be aware of the basic principles of management of envenomation and how to seek expert support. It is important for doctors to know what types of venomous animal are likely to occur in their geographical area (hospital hinterland; see p. 241) and the types of envenoming they may cause.

## Venom

Venom is a complex mixture of diverse components, often with several separate toxins that can cause adverse effects in humans, with each potentially capable of multiple effects (Box 11.1). Venom is produced at considerable metabolic cost, so is used sparingly; only some bites/stings by venomous animals result in significant envenoming, the remainder are 'dry bites'. The concept of dry bites is important in understanding approaches to first aid and medical management.

## Venomous animals

There are many animal groups that contain venomous species (Box 11.2). The epidemiological estimates of envenomation episodes reflect the importance of snakes and scorpions as causes of severe or

lethal envenomation, but also the fragmentary nature of the data. For snakebites, recent studies have proposed widely varying estimates, but even the higher estimates may be too low. In India, studies indicate there are at least 45 000 snakebite-related deaths annually, far above both government figures and previous estimates. In many areas of the rural tropics, health resources are limited and few envenoming cases are either seen or recorded within the official hospital system, compared to the actual community burden of disease. While fatal cases may gain most attention, long-term disability from envenomation affects significantly more people and has a major social and economic cost. The World Health Organization (WHO) has recently recognised snakebite as a 'Neglected Tropical Disease' and this may improve access to funding.

### 11.2 Venomous animals and human envenoming

Phyla	Principal venomous animal groups	Estimated number of human cases/year	Estimated number of human deaths/year
Chordata	Snakes	> 2.5 million	> 100 000
	Spiny fish	? > 100 000	Close to zero
	Stingrays	? > 100 000	? < 10
Arthropoda	Scorpions	> 1 million	? < 5000
	Spiders	? > 100 000	? < 100
	Paralysis ticks	? > 1000	? < 10
	Insects	? > 1 million	? > 1000*
Mollusca	Cone snails	? < 1000	? < 10
	Blue-ringed octopus	? < 100	? < 10
Coelenterata	Jellyfish	? > 1 million	? < 10

\*Social insect stings cause death by anaphylaxis rather than primary venom toxicity, except for massive multiple sting attacks.

### 11.1 Key venom effects\*

Venom component	Clinical effects	Type of venomous animal
<b>Neurotoxin</b>		
Paralytic	Flaccid paralysis (may develop in a <i>descending</i> pattern, commencing first in cranial nerves, or in an <i>ascending</i> pattern, with early ataxia)	Some snakes (descending) Paralysis ticks (ascending) Cone snails (descending) Blue-ringed octopus (descending)
Excitatory	Neuroexcitation: autonomic storm, cardiotoxicity, pulmonary oedema	Some scorpions, spiders, jellyfish (irukandji)
<b>Myotoxins</b>	Systemic or local myolysis	Some snakes
<b>Cardiotoxins</b>	Direct or indirect cardiotoxicity; cardiac collapse, shock	Some snakes, scorpions, spiders and jellyfish (box jellyfish)
<b>Haemostasis system toxins</b>	Variation from rapid coagulopathy and bleeding to thrombosis, deep venous thrombosis and pulmonary emboli	Many snakes and a few scorpions ( <i>Hemiscorpius</i> ) Brazilian caterpillars ( <i>Lonomia</i> )
<b>Haemorrhagic toxins</b>	Local vessel damage, fluid extravasation, blistering, ecchymosis, shock	Mainly some snakes
<b>Nephrotoxins</b> (direct or indirect)	Renal damage	Some snakes, massed bee and wasp stings
<b>Necrotoxins</b>	Local tissue injury/necrosis, shock	Some snakes, a few scorpions ( <i>Hemiscorpius</i> ), spiders (recluse spiders), jellyfish and stingrays
<b>Allergic toxins</b>	Induction of acute allergic response (direct and indirect)	Almost all venoms but particularly those of social insects (i.e. bees, wasps, ants)

\*All venom components have lethal potential.  
Copyright © Julian White.

Snakebite occurs frequently in low resource areas of the rural tropics and so is an important poverty trap; it is also a predominantly occupational disease, with farmers and other agricultural workers at particularly high risk. Although snakebite is undoubtedly the most impactful form of envenoming globally, there are some areas where scorpion stings have a higher impact on health systems than snakebite.

Stings by social insects such as bees and wasps may also cause lethal anaphylaxis and mass stings may cause severe, even lethal, envenomation. Other venomous animals may commonly envenom humans, but cause mostly non-lethal effects. A few animals only rarely envenom humans, but have a high potential for severe or lethal envenoming. These include box jellyfish, cone snails, blue-ringed octopus, paralysis ticks and Australian funnel web spiders. Within any given group, particularly snakes, there may be a wide range of clinical presentations. Some are described here, but for a more detailed discussion of the types of venomous animal, their venoms and their effects on humans, see [toxinology.com](http://toxinology.com).

## Clinical effects

With the exception of dry bites, where no significant toxin effects occur, venomous bites/stings can result in three broad classes of effect.

### Local effects

These vary from trivial to severe (Box 11.3). There may be minimal or no local effects with some snakebites (not even pain), yet lethal systemic envenoming may still be present (e.g. kraits in Asia). For other species, local effects predominate over systemic, and for some, (e.g. certain snakes) both are important (p. 240). Some species commonly cause local necrosis, notably some snakes, brown recluse spiders, an Iranian scorpion (*Hemiscorpius lepturus*) and some stingrays. Globally, amputations secondary to snakebite are an important cause of long-term morbidity and social disadvantage.

### General systemic effects

By definition, these are non-specific (see Box 11.3). Shock is an important complication of major local envenoming by some snake species and if inadequately treated can prove lethal, especially in children.

## 11.3 Local and systemic effects of envenomation

### Local effects

- Pain
- Sweating
- Erythema
- Major direct tissue trauma (e.g. stingray injuries)
- Blistering
- Necrosis
- Swelling
- Bleeding and bruising

### Non-specific systemic effects

- Headache
- Nausea
- Vomiting and diarrhoea
- Abdominal pain
- Tachycardia or bradycardia
- Hypertension or hypotension
- Pulmonary oedema
- Dizziness
- Collapse
- Convulsions
- Shock
- Cardiac arrest

### Specific systemic effects

- Neurotoxic flaccid paralysis (descending or ascending)
- Excitatory neurotoxicity (catecholamine storm-like and similar)
- Rhabdomyolysis (systemic or local)
- Coagulopathy (procoagulants, anticoagulants, fibrinolytics and platelet-active toxins)
- Cardiotoxicity (decreased/abnormal cardiac function or arrhythmia or arrest)
- Acute kidney injury (polyuria or oliguria or anuria or isolated elevated creatinine/urea)

Copyright © Julian White.

## Specific systemic effects

These are important in both diagnosis and treatment.

- *Neurotoxic flaccid paralysis* can develop very rapidly, progressing from mild weakness to full respiratory paralysis in less than 30 minutes (blue-ringed octopus bite, cone snail sting), or may develop far more slowly, over hours (e.g. kraits, some cobras) to days (paralysis tick). For neurotoxic snakes, the cranial nerves are usually involved first, with bilateral ptosis a common initial sign, often progressing to partial and later complete ophthalmoplegia, fixed dilated pupils, drooling and loss of upper airway protection (p. 240). From this, paralysis may extend to the limbs, with weakness and loss of deep tendon reflexes, the neck ('broken neck' sign), then finally respiratory paralysis affecting the diaphragm.
- *Excitatory neurotoxins* cause an 'autonomic storm', often with profuse sweating (p. 240), variable cardiac effects and cardiac failure, sometimes with pulmonary oedema (notably, Australian funnel web spider bite, some scorpions such as Indian red scorpion). This type of envenomation can be rapidly fatal (many scorpions, funnel web spiders), or may cause distressing symptoms with a lesser risk of death (widow spiders, banana spiders).
- *Myotoxicity* can be localised in the bitten limb, or systemic, affecting mostly skeletal muscles. It can initially be silent, then present with generalised muscle pain, tenderness, myoglobinuria (p. 241) and substantial rises in serum creatine kinase (CK). Secondary renal failure can precipitate potentially lethal hyperkalaemic cardiotoxicity.
- *Cardiotoxicity* is often secondary, but symptoms and signs are non-specific in most cases. For some scorpions, envenomation can cause direct cardiac effects, including decreased cardiac output, arrhythmias and pulmonary oedema.
- *Haemostasis system toxins* cause a variety of effects, depending on the type of toxin (Fig. 11.1). Coagulopathy may present as bruising and bleeding from the bite site (p. 240), gums and intravenous sites. Surgical interventions are high risk in such cases. Other venoms cause thrombosis, usually presenting as deep venous thrombosis (DVT), pulmonary embolus or stroke (particularly Caribbean/Martinique vipers).
- *Haemorrhagic toxins* (associated with some snakebites) cause vascular damage, especially in the bitten limb, with extravasation of fluid and sometimes hypotensive shock. They may also cause internal bleeding such as retroperitoneal haemorrhage. The role of these toxins in causing late-developing capillary leak syndrome (p. 240) is uncertain (seen notably with Russell's viper),
- *Renal damage* in envenoming is mostly secondary, although some species (such as Russell's vipers) can cause primary renal damage. The presentation is similar in both scenarios, with changes in urine output (polyuria, oliguria or anuria), proteinuria, or rises in creatinine and urea. In cases with intravascular haemolysis, secondary renal damage is likely. The clinical effects of specific animals in different regions of the world are shown in Boxes 11.4–11.6.

## General approach to the envenomed patient

### First aid

First aid can be crucial in determining the outcome for envenomed patients, yet throughout much of the world inappropriate and dangerous first aid is often administered.

A significant proportion of venom is transported from the bite/sting site via the lymphatic system, particularly for venoms with larger molecular weight toxins, such as many snake venoms. It is recommended that for most forms of envenoming, the patient should be kept still, the bitten limb immobilised with a splint and vital systems supported, where required. A patent upper airway should be ensured and respiratory

Fig. 11.1 Sites of action of venoms on the haemostasis system. Copyright © Julian White.

11.4 Selected important venomous animals in Asia			
Scientific name <sup>1</sup>	Common name	Clinical effects	Antivenom/antidote/treatment
<b>South Asia</b>			
<i>Bungarus</i> spp. (E)	Kraits	Flaccid paralysis <sup>2,3</sup> , myolysis <sup>4</sup> , hyponatraemia <sup>5</sup>	Indian PV or specific
<i>Naja</i> spp. (E)	Cobras	Flaccid paralysis <sup>3</sup> , local necrosis/blistering, shock	Indian PV or specific
<i>Ophiophagus hannah</i> (E)	King cobra	Flaccid paralysis <sup>3</sup> , local necrosis, shock	Indian PV or specific
<i>Echis</i> spp. (Vv)	Saw-scaled vipers	Procoagulant coagulopathy, local necrosis/blistering, renal failure	Indian PV or specific
<i>Daboia russellii</i> (Vv)	Russell's viper	Procoagulant coagulopathy, local necrosis/blistering, myolysis, renal failure, shock, flaccid paralysis <sup>2</sup>	Indian PV or specific
<i>Hypnale</i> spp. (Vc)	Hump-nosed vipers	Procoagulant coagulopathy, shock, renal failure	No available AV; Indian PV unlikely to be effective
<i>Trimeresurus</i> <sup>6</sup> spp. (Vc)	Green pit vipers	Procoagulant coagulopathy, local necrosis, shock	Indian PV unlikely to be effective; consider specific AV from Thailand
<i>Hottentotta</i> spp. (Sc)	Indian scorpions	Neuroexcitation, cardiotoxicity	Indian specific AV Prazosin
<b>East Asia</b>			
<i>Bungarus</i> spp. (E)	Kraits	Flaccid paralysis <sup>2,3</sup>	Specific AV from country
<i>Naja</i> spp. (E)	Cobras (some spitters)	Flaccid paralysis <sup>3</sup> , local necrosis/blistering, shock	Specific AV from country
<i>Ophiophagus hannah</i> (E)	King cobra	Flaccid paralysis <sup>3</sup> , local necrosis, shock	King cobra AV
<i>Calloselasma rhodostoma</i> (Vc)	Malayan pit viper	Procoagulant coagulopathy, local necrosis/blistering, renal failure, shock	Specific AV from country
<i>Daboia siamensis</i> (Vv)	Russell's viper	Procoagulant coagulopathy, local necrosis/blistering, renal failure, capillary leak syndrome, shock, anterior pituitary haemorrhage and failure	Specific AV from country
<i>Gloydius</i> spp. (Vc)	Mamushis, pit vipers	Procoagulant coagulopathy, local necrosis/blistering, shock, renal failure, flaccid paralysis <sup>2</sup>	Specific AV from country
<i>Trimeresurus</i> <sup>6</sup> spp. (Vc)	Green pit vipers, habus	Procoagulant coagulopathy, local necrosis/blistering, shock	Specific AV from country
<i>Hydrophis schistosus</i> + other species	Sea snakes (all species globally)	Flaccid paralysis and/or myolysis	Seqirus sea snake AV

<sup>1</sup>Family names: C = 'Colubridae' (mostly 'non-venomous'; family subject to major taxonomic revisions); E = Elapidae (all venomous); Sc = Scorpionoidea; Vc = Viperidae Crotalinae (New World and Asian vipers); Vv = Viperidae viperinae (Old World vipers). <sup>2</sup>Pre-synaptic. <sup>3</sup>Post-synaptic. <sup>4</sup>Only reported so far for *B. candidus*, *B. niger* and *B. caeruleus*. <sup>5</sup>Only reported so far for *B. multicinctus* and *B. candidus*. <sup>6</sup>Genus is subject to major taxonomic change (split into at least eight genera). (AV = antivenom; PV = polyvalent)

### 11.5 Selected important venomous animals in the Americas and Australia

Scientific name <sup>1</sup>	Common name	Clinical effects	Antivenom/antidote/treatment
<b>North America</b>			
<i>Crotalus</i> spp. (Vc)	Rattlesnakes	Procoagulant coagulopathy, local necrosis/blistering (flaccid paralysis <sup>2</sup> rare), shock	CroFab (Fab') AV or Anavip (F(ab') <sub>2</sub> ) AV
<i>Sistrurus</i> spp. (Vc)	Massasaugas	Procoagulant coagulopathy, local necrosis/blistering, shock	CroFab (Fab') AV or Anavip (F(ab') <sub>2</sub> ) AV
<i>Agkistrodon</i> spp. (Vc)	Copperheads and moccasins	Procoagulant coagulopathy, local necrosis/blistering, shock	CroFab (Fab') AV or Anavip (F(ab') <sub>2</sub> ) AV
<i>Micrurus</i> spp. (E)	Coral snakes	Flaccid paralysis <sup>3</sup>	Bioclon Coralmyrn AV
<i>Latrodectus mactans</i>	Widow spider	Neuroexcitation	MSD Widow spider AV
<i>Centruroides sculpturatus</i>	Arizona bark scorpion	Neuroexcitation	Bioclon Anascorp AV
<b>Central and South America</b>			
<i>Crotalus</i> spp. (Vc)	Rattlesnakes	Flaccid paralysis <sup>2</sup> , myolysis, procoagulant coagulopathy, shock, renal failure	Specific AV from country
<i>Bothrops</i> spp. (Vc)	Lancehead vipers	Procoagulant coagulopathy, local necrosis/blistering, shock, renal failure	Specific AV from country
<i>Bothriechis</i> spp. (Vc)	Eyelash pit vipers	Shock, pain and swelling	Specific AV from country
<i>Lachesis</i> spp. (Vc)	Bushmasters	Procoagulant coagulopathy, shock, renal failure, local necrosis/blistering	Specific AV from country
<i>Micrurus</i> spp. (E)	Coral snakes	Flaccid paralysis <sup>2,3</sup> , myolysis, renal failure	Specific AV from country
<i>Tityus serrulatus</i>	Brazilian scorpion	Neuroexcitation, shock	Instituto Butantan scorpion AV
<i>Loxosceles</i> spp.	Recluse spiders	Local necrosis	Instituto Butantan spider AV
<i>Phoneutria nigriventer</i>	Banana spider	Neuroexcitation, shock	Instituto Butantan spider AV
<i>Potamotrygon, Dasyatis</i> spp.	Freshwater stingrays	Necrosis of bite area, shock, severe pain and oedema	No available AV; good wound care
<b>Australia</b>			
<i>Pseudonaja</i> spp. (E)	Brown snakes	Procoagulant coagulopathy, renal failure, flaccid paralysis <sup>2</sup> (rare)	Seqirus brown snake AV or PVAV
<i>Notechis</i> spp. (E)	Tiger snakes	Procoagulant coagulopathy, myolysis, flaccid paralysis <sup>2,3</sup> , renal failure	Seqirus tiger snake AV or PVAV
<i>Oxyuranus</i> spp. (E)	Taipans	Procoagulant coagulopathy, flaccid paralysis <sup>2,3</sup> , myolysis, renal failure	Seqirus taipan or PVAV
<i>Acanthophis</i> spp. (E)	Death adders	Flaccid paralysis <sup>3</sup>	Seqirus death adder or PVAV
<i>Pseudechis</i> spp.	Black and mulga snakes	Anticoagulant coagulopathy, myolysis, renal failure	Seqirus black snake AV or PVAV
<i>Hydrophis schistosus</i> + other species	Sea snakes (all species globally)	Flaccid paralysis and/or myolysis	Seqirus sea snake AV
<i>Atrax, Hadronyche</i> spp.	Funnel web spiders	Neuroexcitation, shock	Seqirus funnel web spider AV
<i>Latrodectus hasseltii</i>	Red back spider	Neuroexcitation, pain and sweating	Seqirus red back spider AV
<i>Chironex fleckeri</i>	Box jellyfish	Neuroexcitation, cardiotoxicity, local necrosis	Seqirus box jellyfish AV
<i>Synanceia</i> spp.	Stonefish	Severe local pain	Seqirus stonefish AV

support provided, if required. For some animals, notably snakes in certain regions, the use of a local pressure pad bandage over the bite site (Myanmar) or a pressure immobilisation bandage (Australia, New Guinea) is recommended.

Ineffective or dangerous first aid, such as suction devices, 'cut and suck', local chemicals, snake stones (stones of some sort placed over the snakebite), electric shock devices and tourniquets, should not be used. Tourniquets, in particular, have the potential to cause catastrophic ischaemic distal limb injuries in snakebite when applied too narrowly or too tightly, or left on too long. Caution is required when removing tourniquets or other constricting first aid, as there may be a sudden rush of venom into the circulation causing rapid effects and cardiorespiratory collapse.

### Transporting patients

Where possible, transport should be brought to the patient. It is vital to obtain medical assessment and intervention at the earliest opportunity, so any delay in transporting the patient to a medical facility should be avoided. Severely envenomed patients may develop life-threatening problems during transport, such as shock or respiratory failure, so ideally the transport method should allow for management of these problems en route.

In resource-poor environments, simple solutions for rapid transport have been successfully employed, such as motorbikes or similar with the patient supported between the driver in front and another person behind the patient. However, this method cannot cope with a patient developing airway compromise or respiratory failure, such as from developing neurotoxicity.

## 11.6 Selected important venomous animals in Africa and Europe

Scientific name <sup>1</sup>	Common name	Clinical effects	Antivenom/antidote/treatment
<b>Africa</b>			
<i>Naja</i> spp. (E)	Cobras		
	Non-spitters	Flaccid paralysis <sup>3</sup> ± local necrosis/blistering	South African PV or other appropriate African-specific AV
	Spitters	Local necrosis/blistering (flaccid paralysis <sup>3</sup> uncommon)	South African PV or other appropriate African-specific AV
<i>Dendroaspis</i> spp. (E)	Mambas	Mamba neurotoxic flaccid paralysis and muscle fasciculation, shock, necrosis (uncommon)	South African PV or other appropriate African-specific AV
<i>Hemachatus haemachatus</i> (E)	Rinkhals	Flaccid paralysis <sup>3</sup> , local necrosis, shock	South African PV
<i>Atheris</i> spp. (Vv)	Bush vipers	Procoagulant coagulopathy, shock, pain and swelling	No available AV (can try South African AV)
<i>Bitis</i> spp. (Vv)	Puff adders etc.	Procoagulant coagulopathy, shock, cardiotoxicity, local necrosis/blistering	South African PV or other appropriate African-specific AV
<i>Causus</i> spp. (Vv)	Night adders	Pain and swelling	No available AV
<i>Echis</i> spp. (Vv)	Carpet vipers	Procoagulant coagulopathy, shock, renal failure, local necrosis/blistering	Specific anti- <i>Echis</i> AV for species/geographical region or other appropriate African-specific AV
<i>Cerastes</i> spp. (Vv)	Horned desert vipers	Procoagulant coagulopathy, local necrosis, shock	Specific or polyspecific AV covering <i>Cerastes</i> from country of origin
<i>Dispholidus typus</i> (C)	Boomslang	Procoagulant coagulopathy, shock	Boomslang AV
<i>Androctonus</i> spp.	North African scorpions	Neuroexcitation	Specific scorpion AV (Algeria, Tunisia, Sanofi Pasteur Scorpifav)
<i>Leiurus quinquestriatus</i>	Yellow scorpion	Neuroexcitation, shock	Specific scorpion AV (Algeria, Tunisia, Sanofi Pasteur Scorpifav)
<b>Europe</b>			
<i>Vipera</i> spp. (Vv)	Vipers and adders	Shock, local necrosis/blistering, procoagulant coagulopathy (flaccid paralysis <sup>2</sup> rare)	ViperaTab AV or Zagreb AV or Sanofi Pasteur Viperfav AV

<sup>1</sup>For family name, see Box 11.4. <sup>2</sup>Pre-synaptic. <sup>3</sup>Post-synaptic.  
(AV = antivenom; PV = polyvalent)

### Assessment and management in hospital

On arrival at a health station or hospital, there are two immediate priorities:

- identifying and treating any life-threatening problems (e.g. circulatory shock, respiratory failure; see Ch. 16)
- determining whether envenomation has occurred and if that requires urgent treatment.

### Assessment and management of life-threatening problems

Patients who are seriously envenomed must be identified early so that appropriate management is not delayed. Critically ill patients must be resuscitated (Ch. 9) and this takes precedence over administration of any antivenom. Clinicians should look for signs of:

- shock/hypotension
- airway and/or respiratory compromise (likely to be secondary to flaccid paralysis)
- major bleeding, including internal bleeding (especially intracranial, intra- or retro-peritoneal)
- impending limb compromise from inappropriate first aid (e.g. a tourniquet).

In a patient with severe neurotoxic flaccid paralysis, who is still able to maintain sufficient respiratory function for survival, clinical assessment

may erroneously suggest irretrievable brain injury (fixed dilated pupils, absent reflexes, no withdrawal response to painful stimuli, no movement of limbs, fixed forward gaze with gross ptosis; p. 240) when, in fact, the patient is conscious and terrified.

### Assessment for evidence of envenoming

As in other areas of medicine, comprehensive assessment of a patient bitten/stung by a venomous animal requires a good history, a careful targeted examination and, where appropriate, 'laboratory' testing (though the latter may just consist of simple bedside tests performed by the doctor; p. 241). Animals that are unlikely to cause serious envenomation in humans should be identified so that inappropriate admission and intervention are avoided. Occasionally, patients may be unaware they have been bitten/stung and thus provide a misleading history. In regions of the world where keeping or handling venomous animals is illegal, patients may be reticent in giving a truthful history. Multiple bites or stings are more likely to cause major envenoming.

The following key questions should be asked:

- When was the patient exposed to the venomous bite/sting?
- Was the organism causing it seen and what did it look like (size, colour)?
- What were the circumstances (on land, in water etc.)?
- Was there more than one bite/sting? (multiple bites/stings are more likely to be severe)

- What first aid was used, how quickly was it applied and how long has it been in place?
- What symptoms has the patient had (local and systemic)?
- Are there symptoms suggesting systemic envenomation (paralysis, rhabdomyolysis, coagulopathy etc.)?
- Is there any significant past medical history and medication use?
- Is there a past exposure to antivenom/venom and allergies?

If patients state that they have been bitten by a particular species, ensure this information is accurate. Private keepers of venomous animals may not have accurate knowledge of what they are keeping and misidentification of a snake, scorpion or spider can have dire consequences if the wrong antivenom is used.

An outline of some principal findings on examination of the envenomed patient is shown on page 240. The patient may have a cluster of clinical features suggestive of a particular type of envenoming (see Box 11.1). There are documented envenoming syndromes for some groups of snakes that, in some regions, can guide diagnosis and treatment (see Box 11.7). Detail of this syndromic approach is available in free WHO guides on snakebite in Asia and in Africa.

Even with dangerously venomous animals, some bites/stings will be dry bites and will not require antivenom. The time to onset of first symptoms and signs of envenomation is variable, depending on both animal and patient factors. It may range from a matter of minutes post-bite/sting to 24 hours later in some cases. Therefore, if the initial assessment is normal, it must be repeated multiple times during the first 24 hours. Some types of envenomation will not cause symptoms or signs at all, or may appear very late, long after the optimum time for treatment has passed. Evidence of envenomation may become apparent only through laboratory testing.

### Laboratory investigations

Specific tests for venom are currently commercially available only for Australian snakebites, but may be developed for snakebites in other regions. They are not available for other types of envenomation, where venom concentrations are low. For snakebite, a screen for envenomation includes full blood count, coagulation screen, urea and electrolytes, creatinine, CK and electrocardiogram (ECG). Lung function tests, peripheral oximetry or arterial blood gases may be indicated in cases with potential or established respiratory failure. In areas without access to routine laboratory tests, the 20-minute whole-blood clotting test (20WBCT) is useful (p. 241).

### Treatment

Once a diagnosis of likely envenoming has been made, the next and urgent decision is whether to give antivenom. However, antivenom may not be the only crucial treatment required. For a snakebite by a potentially lethal species such as Russell's viper, the patient may have local effects with oedema, blistering, necrosis and resultant fluid shifts causing shock, and at the same time have systemic effects such as intractable vomiting, coagulopathy, paralysis and secondary renal failure. Specific treatment with antivenom will be required to reverse the coagulopathy and may prevent worsening of the paralysis and reduce the vomiting, but will not greatly affect the local tissue damage or the renal failure or shock. The latter will require intravenous fluid therapy, possibly respiratory support, renal dialysis and local wound care, perhaps including antibiotics. In Myanmar at least, each hour of delay in giving antivenom after Russell's viper bite markedly increases the likelihood of developing renal failure.

Each venomous animal will cause a particular pattern of envenomation, requiring a tailored response (envenoming syndrome). Listing all of these is beyond the scope of this chapter (see 'Further information').

## 11.7 Snakebite envenomation syndromes for South-East Asia

Clinical definition/characteristics of syndrome	Likely snakes causing the syndrome
<b>Syndrome 1</b>	
Local envenoming (swelling etc.) + bleeding, clotting disturbances	Viper bite (many possible species)
<b>Syndrome 2</b>	
Local envenoming (swelling etc.) + bleeding, clotting disturbances + shock or AKI	Russell's viper
2a – ± conjunctival oedema and acute pituitary insufficiency	2a – Russell's viper in Myanmar and South India
2b – ± bilateral ptosis, external ophthalmoplegia, flaccid paralysis, dark urine (myoglobinuria)	2b – Russell's viper in Sri Lanka and South India
<b>Syndrome 3</b>	
Local envenoming (swelling etc.) + flaccid paralysis (bilateral ptosis, ophthalmoplegia, etc.)	Cobra or king cobra
<b>Syndrome 4</b>	
Minimal or no local envenoming + flaccid paralysis (bilateral ptosis, ophthalmoplegia, etc.)	
4a – If bitten on land (patient sleeping on ground at night) ± abdominal pain	4a – krait
4b – If bitten in water (sea, some lakes) ± dark urine (myoglobinuria)	4b – sea snake
4c – If bitten on land in New Guinea ± coagulopathy	4c – Australasian Elapid (taipan, small-eyed snake, etc.)
<b>Syndrome 5</b>	
Variable local effects + flaccid paralysis + dark urine (myoglobinuria) and AKI	
5a – If bitten on land (sleeping on ground)	5a – krait
5b – If bitten in water (sea, some lakes) + no coagulopathy	5b – sea snake
5c – If bitten on land + coagulopathy/bleeding	5c – Russell's viper (Sri Lanka and South India)
<small>(AKI = acute kidney injury). After World Health Organization, Regional Office for South-East Asia. Guidelines for the management of snake-bites, 2nd edn; 2016.</small>	

### Antivenom

Antivenom, sometimes inappropriately labelled as 'anti-snake venom' (ASV), is the most important tool in treating envenomation. It is made by hyperimmunising an animal, usually horses, to produce antibodies against venom. Once refined, these bind to venom toxins and render them inactive or allow their rapid clearance. Antivenom is available only for certain venomous animals and cannot reverse all types of envenomation. With a few exceptions, it should be given intravenously, with adrenaline (epinephrine) ready in case of anaphylaxis. It should be used only when clearly indicated and indications will vary between venomous animals (Box 11.8). It is critical that the correct antivenom is used at the appropriate dose. Doses vary widely between antivenoms. In some situations (such as South Asia), pre-treatment with subcutaneous adrenaline may reduce the chance of anaphylaxis to antivenom.

Antivenom can sometimes reverse post-synaptic neurotoxic paralysis ( $\alpha$ -bungarotoxin-like neurotoxins), but will not usually reverse established pre-synaptic paralysis ( $\beta$ -bungarotoxin-like neurotoxins), so should be given before major paralysis has occurred (Fig. 11.2). Coagulopathy is best reversed by antivenom, but even after all venom is neutralised, there

11.8 Indications for antivenom	
<b>General indications</b>	
<ul style="list-style-type: none"> <li>Shock/cardiac collapse</li> <li>Respiratory compromise</li> <li>Rapidly increasing swelling of the bitten limb</li> </ul>	<ul style="list-style-type: none"> <li>Active bleeding</li> <li>Intractable non-specific symptoms, including recurrent vomiting</li> </ul>
<b>Specific indications</b>	
<ul style="list-style-type: none"> <li>Developing paralytic features (ptosis etc.)</li> <li>Developing rhabdomyolysis</li> <li>Developing coagulopathy</li> </ul>	<ul style="list-style-type: none"> <li>Developing renal failure</li> <li>Developing neuroexcitatory envenoming</li> </ul>

**Fig. 11.2** Principal snake venom neurotoxins acting at the neuromuscular junction (NMJ). The pre-synaptic neurotoxins ( $\beta$ -bungarotoxin-like) bind to the cell membrane of the terminal axon (1), form a synaptosome (2) and enter the cell, where they disrupt acetylcholine (ACh) production (3) and damage intracellular structures, including ion channels (4). On initial entry, they cause release of excess ACh, followed by cessation of all ACh release, causing irreversible paralysis until the cell is repaired (days to weeks later). The post-synaptic neurotoxins ( $\alpha$ -bungarotoxin-like) bind adjacent to the ACh receptor on the external surface of the muscle end plate and block ACh binding (5), thereby ceasing neurotransmission. Because this action is external to the cell and does not cause cell damage, it is potentially a reversible paralysis. Copyright © Julian White.

may be a delay of hours before normal coagulation is restored. More antivenom should not be given because coagulopathy has failed to normalise fully in the first 1–3 hours (except in very particular circumstances). Thrombocytopenia may persist for days despite antivenom. The role of antivenom in reversing established rhabdomyolysis and renal failure is uncertain. Antivenom may help limit local tissue effects or injury in the bitten limb, but this is quite variable and time-dependent. Neuroexcitatory envenoming can respond very well to antivenom (Australian funnel web

spider bites and Mexican, South American and Indian scorpion stings), but there is controversy about the effectiveness of antivenom for some species (some North African and Middle Eastern scorpions). The role of antivenom in limiting local venom effects, including necrosis, is also controversial; it is most likely to be effective when given early.

All patients receiving antivenom are at risk of both early and late adverse reactions, including anaphylaxis (early; not always related to immunoglobulin E (IgE)) and serum sickness (late).

## Non-antivenom treatments

Anticholinesterases are used as an adjunctive treatment for post-synaptic paralysis.

Prazosin, an  $\alpha$ -adrenoceptor antagonist ( $\alpha$ -blocker) has been used in the management of hypertension or pulmonary oedema in scorpion sting cardiotoxicity, particularly for Indian red scorpion stings, though antivenom is now the preferred treatment.

Antibiotics are not routinely required for most bites/stings, though a few animals, such as some South American pit vipers and stingrays, regularly cause significant wound infection or abscess. Tetanus is a risk in some types of bite or sting, such as snakebite, but intramuscular toxoid should not be given until any coagulopathy is reversed.

Mechanical ventilation (p. 207) is vital for established respiratory paralysis that will not reverse with antivenom and may be required for prolonged periods (up to several months in some cases).

Fasciotomy as a treatment for potential compartment syndrome or severe limb swelling is an overused and often disastrous surgical intervention in snakebite and is associated with poor functional outcomes. It should be reserved as a treatment of last resort and used only in cases where compartment syndrome is confirmed by intra-compartment pressure measurement and after first trying limb elevation, antivenom and ensuring that any coagulopathy has resolved.

## Follow-up

Cases with significant envenomation and those receiving antivenom should be followed up to ensure any complications have resolved and to identify any delayed envenoming.

## Prevention

Community education promoting prevention should be an important part of health delivery, particularly in low resource nations where access to health care may be suboptimal. For snakebite, avoiding sleeping on the ground, walking barefoot or without illumination at night should be emphasised. Use of mosquito netting over raised beds may prevent both mosquito-borne diseases and nocturnal snakebite (kraits in Asia). Use of boots in paddy fields may reduce the risk of snakebite. Installation of glossy tiles around the base of buildings may discourage scorpion entry in endemic areas.

## Envenomation by specific animals

### Venomous snakes

Venomous snakes represent the single most important cause of envenomation globally, affecting millions of humans annually and resulting in large numbers of deaths and patients left with long-term disability. Of the 3000-plus snake species, more than 1000 either are venomous or produce oral toxins. The most important venomous snake families are the Viperidae (vipers; includes typical vipers (subfamily Viperinae) and pit vipers, with heat-sensing pit organs (subfamily Crotalinae)) and the Elapidae (cobras, kraits, mambas, coral snakes, sea snakes, Australian snakes). However, there are also dangerous species among the Atractaspidinae (side-fanged burrowing vipers of Africa and the Middle East) and the non-front-fanged colubroids (NFFC snakes; several

families, including the 'back-fanged' boomslang and vine snakes of Africa and the keelbacks of Asia).

A selection of important species is included in [Boxes 11.4–11.6](#).

### Clinical features and management

As with other forms of envenomation, the management of snakebite follows the standard assessment guidelines described previously (p. 240). The nature of the risks posed will depend on the specific snake fauna in a given region (p. 241). For example, in South Asia, the major snakebite risks are claimed to come from the 'big four': cobras, kraits, Russell's viper and saw-scaled vipers. This list is misleading, though, as it omits other important snakes, including the hump-nosed vipers, king cobra and green pit vipers, all of which can cause severe or lethal envenoming and may not be covered by current Indian antivenoms. Even for those snakes recognised as causing envenoming, there may be major geographical variation in venom and features of envenoming. For Russell's viper (*Daboia* spp.), Sri Lankan specimens can cause rhabdomyolysis and flaccid paralysis, in addition to classic severe coagulopathy, haemorrhage, local bite site injury and acute kidney injury (AKI). Most Indian populations of the same snake are not associated with either rhabdomyolysis or paralysis, but in parts of Southern India may cause anterior pituitary haemorrhage and/or capillary leak syndrome (hypotensive shock plus vascular leakage resulting in pulmonary oedema). Capillary leak syndrome is also encountered with populations of Burmese Russell's viper (Myanmar), where AKI is especially common and severe.

Antivenom raised against venom from one population of snakes may be poorly effective against bites from snakes from other regions; this is particularly true for Russell's vipers. Similarly, each of the several species of saw-scaled vipers (*Echis* spp.) spread from West Africa across the Middle East to South Asia (including Sri Lanka) has specific venoms that may not be neutralised by antivenoms raised against other species in the genus; Indian antivenoms are ineffective against African species. It follows that, in managing snakebite envenomation, it is critically important to choose the appropriate antivenom and to understand that this may not include every antivenom claimed to cover a given species.

It is unwise to assume that everything is known about envenoming by snakes because new clinical information and syndromes are emerging as more detailed studies are carried out. For instance, krait bites (*Bungarus* spp.), long associated with 'painless' bites, later development of devastating flaccid paralysis and a high mortality rate, are now known to have some venom diversity. At least some species can cause rhabdomyolysis (black krait, Bangladesh) and/or severe hyponatraemia, and while bites may be painless, systemic envenomation can cause severe abdominal pain in at least some patients. Among cobra bites, the previous division into 'non-spitting', neurotoxic species and 'spitting', less neurotoxic species that cause local necrosis is less clear. Non-spitters are now known to spit in parts of their range (e.g. *Naja kaouthia* in West Bengal) and may cause local necrosis in addition to paralysis. Previously clear diagnostic indicators for envenomation by particular types of snakes, such as Russell's vipers and saw-scaled vipers causing coagulopathy, have also become less sure, as other snakes, such as hump-nosed vipers (*Hypnale* spp.) and green pit vipers (*Trimeresurus* spp.), found in similar regions, can also cause marked coagulopathy and yet are often not covered by available antivenoms. The ability to cause life-threatening coagulopathy, associated with snakes previously considered harmless, such as the keelbacks in Asia (*Rhabdophis* spp.), can further complicate the diagnostic and management process, as antivenom against these snakes is currently available only in Japan.

## Scorpions

Scorpions are second only to snakes in their venomous impact on humankind. Most medically important scorpions are in the family Buthidae and have complex neuroexcitatory venoms with highly specific ion-channel toxins. Classically, stings by these scorpions (some key genera listed in [Boxes 11.4–11.6](#)) cause moderate to severe local pain and

rapid-onset systemic envenoming with development of a catecholamine storm-like syndrome as the toxins target the nervous system. There may be tachycardia or bradycardia, hyper- or hypotension, profuse sweating, salivation, cardiac dysfunction and pulmonary oedema. Cardiac collapse can occur, especially in children. Other clinical features may vary, depending on the scorpion species.

The Iranian scorpion, *Hemiscorpius lepturus* (principally south-west Iran), causes a quite different presentation, with an initial minor sting, followed by progressive development of bite site or limb necrosis and a potentially lethal systemic envenoming, characterised by intravascular haemolysis, disseminated intravascular coagulation (DIC), secondary renal failure and shock.

### Clinical features and management

The approach to management varies with species and region. In South America, specific antivenoms are routinely used and associated with improved outcomes and reduced mortality. In India, the past reliance on prazosin has been replaced with use of specific antivenom, again with improved outcomes. In contrast, in parts of North Africa, past reliance on antivenom has been replaced with use of cardiac support and arguably poorer outcomes.

In Iran, *H. lepturus* stings are treated with antivenom, though as presentation is often delayed because the sting initially appears to be minor, the role of late antivenom is unclear.

## Spiders

There are vast numbers and great species diversity of spiders, with two broad taxonomic groupings: the more 'primitive' Mygalomorphs (several medically important species, especially Australian funnel web spiders (*Atrax*, *Hadronyche* and *Illawarra*)) and the far more diverse Araneomorphs (main clinically important species in the genera *Latrodectus* (widow spiders), *Loxosceles* (brown recluse spiders) and *Phoneutria* (banana or wandering spiders)).

### Clinical features and management

While spiders and spider bites are common, only those genera noted above commonly cause medically significant effects. In most cases this is a neuroexcitatory envenoming, sometimes similar to severe scorpion envenoming (notable from Australian funnel web spiders), but the recluse spiders cause an often painless bite that develops into local skin necrosis and sometimes a systemic illness similar to that caused by the Iranian scorpion, *H. lepturus*, and with similar lethal potential. Widow spiders cause 'latrodectism', with initial local pain and sweating. In some, the pain becomes severe, sometimes spreading regionally followed by generalised pain, with associated hypertension, nausea and malaise.

For most of these spiders, antivenom remains the key treatment and is life-saving in some cases. Studies suggesting that anti-*Latrodectus* antivenom is ineffective have not been confirmed by independent studies and are in contrast to decades of positive clinical experience.

## Paralysis ticks

Most ticks are vectors for disease but a few species in Australia, North America and parts of Africa can cause flaccid paralysis. Toxins in the saliva act as potent pre-synaptic neurotoxins that can cause gradual-onset ascending flaccid paralysis.

There are no antivenoms for tick paralysis. Treatment is based on removal of all ticks and supportive care, including intubation/ventilation where required. The paralysis usually resolves by about 48 hours following removal of all ticks, although embedded ticks may be hard to find, hiding in the scalp, ears and skin folds.

## Venomous insects

A number of insects are venomous, but very few cause significant envenoming in humans.

## Venomous lepidopterans

The *Lonomia* caterpillars of South America, especially Brazil, have numerous protective venomous spines that, on contact with the skin, can discharge a potent procoagulant venom that can cause a progressive and sometimes fatal consumptive coagulopathy, with terminal haemorrhagic and/or organ failure events. Treatment includes use of a Brazilian specific antivenom and supportive care.

## Venomous hymenopterans

Many bees, wasps, hornets and some ants have modified ovipositors in the abdomen that act as stings, attached to venom glands. The quantity of venom injected in a single sting is insufficient to cause significant envenomation, but as many of these venoms are potentially allergenic, it can cause severe and sometimes fatal anaphylaxis in sensitised persons (p. 183). Massed stings by hundreds of these insects in a swarm, however, can cause life-threatening systemic envenoming, often with intravascular haemolysis, DIC, shock and multi-organ failure. 'Africanised' bees are a particular risk for such attacks in South America and now in parts of North America. The giant wasps and hornets of Asia can similarly cause systemic envenoming with multiple attacks, even from a few individual insects. Invasive ants, such as *Solenopsis* spp., are colonising new regions and can cause both allergic reactions and unpleasant local reactions.

## Marine venomous and poisonous animals

The marine environment is dominated by animal life, and many species utilise toxins, either self-produced or taken up from the environment, to arm themselves for either defence or predation. Many of these animals can cause adverse effects in humans, either as a direct venom effect on bites/stings (venomous spiny fish, sea snakes, stingrays, jellyfish, sea urchins, some starfish, cone snails, selected octopuses etc.), or through poisoning if eaten (fugu, ciguatera, scombroid, several types of shellfish poisoning; p. 236).

For venomous marine animals, there is antivenom available only for sea snakes, which can cause rhabdomyolysis and/or paralytic neurotoxicity; box jellyfish, which can cause very rapid cardiac collapse; and

stonefish, which cause intense sting-site pain and sometimes local necrosis. In general, marine venoms respond to heat; thus a hot water immersion or shower (about 45°C) is effective at reducing local pain, particularly for jellyfish, stinging fish and stingray stings. For stingray stings, the venom may cause local tissue damage both through sting trauma and a venom effect. Wounds penetrating the abdomen or chest are potentially lethal and should be adequately explored, cleaned and allowed to heal by secondary intention, with antibiotic treatment of secondary infection if indicated. For bites by the blue-ringed octopus and stings by cone snails, rapid-acting venom can cause early cardiovascular collapse and flaccid paralysis. Supportive care is crucial in ensuring survival from these potentially lethal and seemingly trivial local wounds. Sea urchin and venomous starfish wounds can result in multiple penetrating spines, which cause pain and act as a nidus for secondary infection, but surgical removal of spines can be difficult and unrewarding. Contact with venomous sessile animals (coral, anemones, some sponges etc.) can result in painful local envenoming.

## Multiple Choice Questions

- 11.1. Snakebite has been classified as a major Neglected Tropical Disease, but venomous snakes are not the most common and important cause of envenoming in some regions. In those regions, such as North Africa, which of these animal groups is the most important?
- A. Spiders
  - B. Hymenopteran insects (bees, wasps and ants)
  - C. Scorpions
  - D. Jellyfish
  - E. Stingrays

Answer: C.

While there are far more spider species than scorpions, and many scorpions are not dangerous for humans, scorpion sting can be severe and life threatening. Scorpion sting causes more hospitalisations than snakebite in some regions such as North Africa, parts of the Middle East and parts of Latin America, including Mexico. Globally hymenopteran insect stings causing major allergy are also important, but with fewer hospitalisations. Jellyfish stings and stingray injuries are important in some regions, but again with comparatively fewer hospitalisations.

- 11.2. Descending neurotoxic flaccid paralysis is a feature of envenoming by a number of animals, both terrestrial and marine, but most notably some species of snakes. Which is the common key first sign to look for as evidence of developing neurotoxicity?
- A. Limb weakness
  - B. Ophthalmoplegia
  - C. Difficulty speaking and swallowing
  - D. Loss of deep tendon reflexes
  - E. Bilateral ptosis

Answer: E.

All of the listed signs can occur with neurotoxic descending flaccid paralysis, but cranial nerves are usually affected first and bilateral ptosis is usually the first clear sign and should be a standard part of repeated examinations of patients with suspected snakebite, as important and frequently tested as pulse, blood pressure and respiratory rate. Ophthalmoplegia often first manifests as partial paralysis affecting medial gaze and generally occurs after ptosis becomes apparent. As neurotoxicity progresses the patient may develop difficulty with speech, swallowing and may start drooling and at this point pharyngeal airway protection may become imperilled and require airway support. Limb weakness and loss of deep tendon reflexes usually occur later in the progression of neurotoxicity. Ideally, as soon as ptosis develops the patient should receive an appropriate antivenom to try to prevent paralysis progressing through to full respiratory paralysis.

- 11.3. Procoagulants in some snake venoms can cause consumption of clotting factors, particularly fibrinogen, resulting in a bleeding tendency. In West Africa which of the following snakes is most likely to cause this type of coagulopathy?
- A. Puff adder
  - B. Night adder
  - C. Spitting cobra
  - D. Saw-scaled viper
  - E. Forest cobra

Answer: D.

Saw-scaled vipers are a classic cause of procoagulant-mediated consumptive coagulopathy throughout their range, including West Africa, where they pose a major hazard to humans. Their venom also contains potent haemorrhagins and severe local and systemic bleeding effects can occur. Cobras do not cause coagulopathy. Puff adders and night adders can cause local bleeding, but not this severe systemic coagulopathy.

- 11.4. Which of the following common causes of snakebite in parts of India and Sri Lanka is not covered by current polyvalent antivenoms available in this region?
- A. Common cobra
  - B. Saw-scaled viper
  - C. Hump-nosed viper
  - D. Russell's viper
  - E. Common krait

Answer: C.

Hump-nosed vipers, *Hypnale* spp., are common in some parts of India and Sri Lanka, causing a significant number of bites and can cause coagulopathy and acute kidney injury in addition to local effects at the bite site. Envenoming by these snakes can appear similar to envenoming caused by Russell's viper and saw-scaled vipers, however their venom is distinct and not used in production of current antivenoms. Therefore these antivenoms are unlikely to provide benefit in treating hump-nosed viper bites. A new antivenom is being developed for Sri Lanka that will include venom from these snakes in the immunising mix and this may become a better treatment option in future, if clinical trials prove both effectiveness and safety.

- 11.5. Most scorpions causing medically significant envenoming have potent neuroexcitatory venoms that cause rapid development of both local pain and systemic envenoming which can, in some cases, cause a catecholamine-storm-like effect, but one scorpion causes a quite different type of envenoming, with minimal initial pain and development over many hours to days of local sting site necrosis, with a systemic illness. Which of the following scorpions causes this local necrotic effect?
- A. *Tityus serrulatus* (Brazil)
  - B. *Hemiscorpius lepturus* (Iran)
  - C. *Leiurus quinquestriatus* (Middle East)
  - D. *Hottentotta tamulus* (India)
  - E. *Androctonus australis* (North Africa)

Answer: B.

Most medically significant scorpions globally are in the family Buthidae and cause local pain and systemic neuroexcitatory envenoming and do not cause sting site tissue injury/necrosis. The Iranian scorpion, *Hemiscorpius lepturus*, is in the family Hemiscorpiidae and is unique amongst scorpions in having a locally necrotic and systemically haemolytic and tissue-damaging venom, similar in clinical presentation to recluse spider (*Loxosceles* spp.) envenoming. In parts of SW Iran it is the most important cause of scorpion stings and despite antivenom, probably because presentation is often delayed until after the optimum time to use antivenom, stings can cause sometimes fatal envenoming, especially in children.

## Medicine in austere environments

### Extremes of temperature 252

The cold environment 252  
Heat-related illness 254

### Acute high altitude illness 256

Illness at high altitude 256  
Subaquatic medicine 257

'Wilderness medicine' can be defined as medical care delivered in environments greater than one hour away from definitive care, however in practice it often represents the care of patients that are multiple hours, if not days, away from the nearest hospital. This covers a broad range of scenarios from expeditions to commercial work and research projects, often in austere conditions. Adventure tourism is also becoming increasingly popular, and projected to grow further in the future.

Delivery of exemplary care in this context is summarised in **Box 12.1**. It involves a core understanding of the interaction between the environment and human health, alongside strong situational awareness and consideration of human factors. As the environment continually alters, whether through population growth, economic development or climate change, it plays an important role in disease causation – one that may increase over time. This chapter deals principally with the acute effects of environmental hazards on individuals and should be read in conjunction with the chapters on Acute Medicine and Critical Illness (**Ch. 9**) and Poisoning (**Ch. 10**).

## Extremes of temperature

### Thermoregulation

Body heat is generated by basal metabolic activity and muscle movement, and lost by four main mechanisms: conduction, convection, evaporation and radiation (**Fig. 12.1**). Body temperature is controlled in the hypothalamus, which is directly sensitive to changes in core temperature and indirectly responds to temperature-sensitive neurons in the skin. The normal 'set-point' of core temperature is tightly regulated within the range  $37 \pm 0.5^\circ\text{C}$ , which is necessary to preserve the normal function of many enzymes and metabolic processes. Aspects of thermoregulation specific to old age are detailed in **Box 12.2**.

### The cold environment

Protective mechanisms in a cold environment include activation of the sympathetic nervous system with cutaneous vasoconstriction, shivering and increases in both heart rate and cardiac contractility. Shivering, an involuntary contraction and relaxation of muscles, is an early adaptive cold response that results in a two- to fivefold increase in heat generation. As core temperature drops these protective mechanisms fail; shivering stops between  $29^\circ\text{C}$  and  $31^\circ\text{C}$ .

### Physiological effects

The cold environment has six main effects on physiological systems:

#### Metabolism

Regional organ blood flow is reduced in the cold environment with marked variation; the kidneys demonstrate the most significant change, similar in response to that seen with haemorrhage or sepsis. The stress response results in glycogenolysis and gluconeogenesis with a relatively defective insulin efficacy resulting in hyperglycaemia.

### 12.1 Key factors in the delivery of exemplary wilderness medicine

- Optimise participant fitness (e.g. pre-departure health screening)
- Understand the patterns of injury and anticipate issues
- Appropriate technical equipment, medical kit and drugs
- Effective logistical support
- Multiple communication options (awareness of limitations of each)
- Understand environmental factors that affect ingress and egress
- Proactive rather than reactive approach (e.g. daily skin checks/blister care)
- Established standard operating procedures (SOPs)

**Fig. 12.1** Mechanisms of heat loss.

### 12.2 Thermoregulation in old age

- **Age-associated changes:** impairments in vasomotor function, skeletal muscle response and sweating mean that older people react more slowly to changes in temperature.
- **Increased comorbidity:** thermoregulatory problems are more likely in the presence of pathology such as atherosclerosis and hypothyroidism, and medication such as sedatives and hypnotics.
- **Hypothermia:** this may arise as a primary event, but more commonly complicates other acute illness, e.g. pneumonia, stroke or fracture.
- **Ambient temperature:** financial pressures and older equipment may result in inadequate heating during cold weather.

### Fluid and electrolytes

As the body cools there is a relative decrease in plasma volume as fluid moves intracellularly with subsequent inadequate tissue perfusion. There is a decrease in intracellular potassium below a core temperature of  $25^\circ\text{C}$ , which is linked to the risk of arrhythmias.

### Respiratory

For every  $1^\circ\text{C}$  reduction in core temperature there is a 6% drop in oxygen consumption. The initial increased respiratory rate declines with ongoing cooling, with animal studies suggesting a cessation of breathing at a core temperature of  $24^\circ\text{C}$ . There is direct respiratory centre depression from a reduction in both oxygen expenditure and production of carbon dioxide.

### Cardiovascular

As the core temperature falls there is a reduction in cardiac output with initial maintenance of stroke volume. At around  $28^\circ\text{C}$  the heart rate is reduced by 50% with a subsequent increased risk of arrhythmias. Initial conduction abnormalities include a sinus bradycardia, progressing to slow atrial fibrillation (AF) and then to ventricular fibrillation (VF). VF may be induced below  $30^\circ\text{C}$  with excessive stimulation/movement, which is why handling of a hypothermic patient needs to be performed with great care.

### Haematological

There is an increased plasma viscosity, with a 150% rise in haematocrit documented at a core temperature of  $25^\circ\text{C}$ . Enzymatic reactions within the coagulation cascade are prolonged, alongside platelet trapping within the liver and spleen, resulting in an increased bleeding risk.

## Neurological

There is a decline in cognitive function in the cold environment with unconsciousness occurring at a core temperature around 28–30°C. Slurred speech, ataxia and paradoxical undressing are all described with lowering core temperatures. Absence of brain electrical activity is seen below 20°C; this is generally considered to be neuroprotective. It is believed that the cold stabilises the blood–brain barrier and cerebral cell membranes that would otherwise be disrupted by hypoxia.

## Hypothermia

Hypothermia is defined as a core temperature below 35°C and can be sub-categorised into primary hypothermia due to environmental exposure and secondary hypothermia due to abnormal thermoregulatory mechanisms as a result of an underlying altered physiological state. Measurement of core temperature can be challenging, with tympanic measurements often considered inaccurate; monitors are often not calibrated below 35.5°C. Alternatives such as oesophageal temperature can be difficult to achieve in practice, and rectal measurements (considered the gold standard measurement) can lag behind the true core temperature.

Traditionally, hypothermia is categorised as mild (32–35°C), moderate (28–32°C) and severe (<28°C), however, newer staging systems, such as the Swiss Staging System, adopted by some ambulance services, define the level of hypothermia based on symptoms (Fig. 12.2). This has been shown to overestimate the degree of hypothermia in around 20% of cases but remains a helpful classification when an accurate core temperature cannot be obtained.

## Management

Following resuscitation, the objectives of management are to rewarm the patient in a controlled manner whilst treating associated hypoxia (by oxygenation and ventilation if necessary), fluid and electrolyte disturbance, and cardiovascular abnormalities. Careful handling is essential to avoid precipitating arrhythmias. The Swiss Staging System can be used to guide treatment at various levels of hypothermia (see Fig. 12.2).

### Mild hypothermia

Continued heat loss can be prevented by sheltering the patient from the cold, replacing wet clothing, covering the head and insulating the patient from the ground. Hibler's method is the best available technique for packaging a patient, which involves wrapping the patient in an insulating layer, followed by an outer vapour-tight layer. Warm drinks and active movement can raise the core temperature by 2°C per hour. Forced-air re-warming blankets and heat packs can increase core temperature by 0.1–3.4°C per hour. Warmed intravenous fluids have been shown to provide no active warming but they do prevent further cooling.

### Severe hypothermia

For severe hypothermia a number of invasive warming methods can be instigated in hospital. This includes bladder lavage, which involves flushing the bladder with 300 mL of warm saline resulting in a 1–2°C rise in core temperature per hour. Thoracic lavage through two unilateral chest drains (anterior and lateral) can result in a 2–3°C rise per hour. A single chest drain approach can be used by clamping a 32–36 French tube for 2–3 minutes after flushing in 300 mL of warm saline, then allowing it to drain.

Extracorporeal membrane oxygenation (ECMO) and cardiopulmonary bypass (CPB) are performed in specialist hospitals and represent the best warming strategies, with increases in core temperature of 6–10°C per hour.

## Cardiac arrest

There are a number of adaptations to resuscitation algorithms for hypothermic patients in cardiac arrest (Box 12.3). There is an old adage that 'you're not dead until you're warm and dead' with documented cases of full recovery following extended periods of ECMO and CPB (Box 12.4). There are, however, some markers of futility. These include: obvious

Stage/core temperature	Symptoms	Treatment
01: 32–35° 	Alert and shivering	Pragmatic support. Warm environment and clean warm clothes. Hot sugary drinks. Active movement – can increase temperature generation by 20 times the basal metabolic rate
02: 28–<32° 	Drowsy and not shivering	Insulate whole body, wind and vapour barrier and external rewarming (warming blanket or chemical packs around axilla and groin). Warm fluids (this prevents further cooling but doesn't actively warm). Try to reduce movement to avoid arrhythmias. Keep horizontal.
03: 24–<28° 	Unconscious with vital signs, no shivering	Same as stage 2 but added airway support as needed. May require more invasive warming methods including extracorporeal membrane oxygenation (ECMO) or cardiopulmonary bypass (CPB)
04: <24° 	Unconscious with no vital signs	Same as stage 3 but manage as cardiac arrest

Fig. 12.2 Swiss Staging System and the treatment of hypothermia.

### 12.3 Management of cardiac arrest in hypothermic patients

- Assessment for signs of life should be extended to 1 minute
- Ventricular fibrillation and ventricular tachycardia can be defibrillated, however if after three shocks there is no response, additional shocks should be delayed until core temperature is >30°C (3-shock 'stacked' sequences are not recommended)
- Withhold adjunctive medications (adrenaline, amiodarone etc.) if the temperature is below 30°C; or double the interval between doses when temperature is 30–35°C

### 12.4 Cases of full recovery following extended periods of ECMO and CPB

- In 1999 a 29-year-old Norwegian radiology registrar fell whilst skiing into an ice waterfall gully. She was cut out after 1 hour and 20 minutes with a core temperature of 13.7°C. Following 9 hours of CPR and CPB she survived with no neurological impairment.
- In 2011 a 7-year-old Swedish girl fell from a cliff into the sea and was found in the water after 3–4 hours with a core temperature of 13.2°C. Following CPR and warming she survived with no neurological impairment.

(CPB = cardiopulmonary bypass; CPR = cardiopulmonary resuscitation; ECMO = extracorporeal membrane oxygenation)

lethal injury, prolonged asphyxia (mouthful of snow etc.), incompressible thorax (distinct from a stiff chest which is common), frozen abdomen, or potassium > 12 mmol/L.

## Cold injury

### Freezing cold injury ('frostbite')

Hypothermia-induced vasoconstriction results in tissue cooling and frostbite refers to ice formation and freezing within the tissue, most commonly affecting the hands and feet (around 90% of cases). Risk factors include alcohol consumption (which impairs decision-making and results

in peripheral vasodilatation), previous frostbite, drug use, inappropriate clothing, fatigue and dehydration. There are two distinct phases to cold injury: a 'cooling–supercooling–freezing' stage during exposure; and a vascular stage during re-warming. When skin tissues cool to below 0°C ice crystal formation causes microvascular and cell damage. During warming, this results in a degree of circulatory failure and fluid loss. The release of inflammatory mediators causes ischaemia and clot production. Re-freezing following warming is particularly destructive, resulting in massive cell inflammatory changes, therefore re-warming should only be initiated if there is no risk of further re-freezing.

Patients often describe an initial numbness and woody sensation followed by a severe pain during warming with a persistent throbbing sensation. Pain can endure for months alongside potentially permanent sensory changes. The skin can look waxy, discoloured or blistered (Fig. 12.3), however prognostication using initial skin changes can be very challenging.

### Management

If concerned about the possibility of cold injury, immediate pre-hospital treatment is to try to shelter from the environment, consume warm drinks, remove shoes, wet clothing and jewellery and re-dress in warm, dry clothing. If there is absolutely no risk of re-freezing then warming the area can be achieved by placing the area into a companion's armpit or groin. Aspirin 75–300mg and ibuprofen 800mg are recommended. Do not rub the area and do not place heat sources directly onto the area. Evacuation for formal medical review should be obtained. Warmed areas need to be made non-load-bearing and therefore prior thought about extraction needs to be considered. Aloe vera gel has anti-prostaglandin effects and can be applied before application of a non-adherent dressing, splinting and elevation of the affected region.

Definitive warming involves placing the affected area into circulating water between 37°C and 42°C with small amounts of antiseptic for around an hour, avoiding contact with the sides of the container. Additional treatment involves fluid replacement with warmed fluids (due to cold diuresis), strong analgesia and blister care. Blisters may present as clear, cloudy or haemorrhagic. Blister management remains controversial, with current evidence recommending débridement of all blisters in hospital (likely under a general anaesthetic) to improve wound healing. There is no evidence for prophylactic antibiotics and tetanus prophylaxis should be given according to local protocols; frostbite wounds are not considered tetanus-prone.

In-hospital management includes specialist imaging (e.g. angiography and technetium bone scanning) to inform prognosis. A combination of thrombolysis and vasodilators (such as nitroglycerin), given within 24 hours, has evidence of good outcomes. Iloprost, a prostacyclin analogue that causes vasodilation and reduces the requirement for amputation, can be given intravenously after 24 hours of injury. Early

Fig. 12.3 Frostbite in a female Everest sherpa.

amputations have a higher morbidity and surgery should be delayed unless there is evidence of sepsis. There is also a potential role for hyperbaric oxygen treatment and this is an area of current research.

### Non-freezing cold injury

This results from prolonged exposure to cold, damp conditions and is often seen in individuals who become wet but are unable to dry out. The important distinction from frostbite is that the tissues do not freeze. It is almost exclusively seen in the lower limb and feet, however concomitant injury to the hands is sometimes seen. It is often described as a patch of numbness, which when rewarmed, changes in colour from pale to red, with associated swelling and pain. These symptoms can last for months or indefinitely; often far longer than an equivalent freezing injury. The pathology remains uncertain but probably involves endothelial injury. Gradual re-warming is associated with less pain than rapid re-warming. The pain and associated paraesthesia are difficult to control with conventional analgesia and may benefit from early use of amitriptyline. The patient is at risk of further damage on subsequent exposure to the cold.

## Heat-related illness

Heat-related illness defines a spectrum of pathology from benign heat oedema to lethal heat stroke, the definitions of which are found in Box 12.5. There is a growing risk of heat-related illness with global temperatures predicted to rise by between 1.7°C and 5.6°C within this century alone; the World Health Organization predicts over 250 000 additional deaths a year from 2050 as a result of heat exposure.

Heat-related illness is often categorised as either environmental or exertional heat illness depending on the primary underlying mechanism. Environmental heat illness results from elevated ambient temperatures,

### 12.5 Definitions of heat-related illness

Heat-related illness	Definition
Heat oedema	Mild swelling to the limbs during the first few days of heat exposure due to increased plasma volume, peripheral vasodilation and interstitial pooling of blood
Heat cramps	Muscle spasms related to sodium loss. Generally occur after exercise in non-acclimatised individuals who sweat freely and replace losses with water or other hypotonic solutions, so they become salt depleted. Salt supplementation reduces the incidence
Heat syncope	Heat syncope refers to a multi-factorial syndrome involving transient loss of consciousness in the context of heat exposure with a relatively rapid return to normal function and baseline. Contributing factors may include peripheral vasodilation, orthostatic pooling of blood, prolonged standing, advanced age and dehydration, as well as coexisting medical conditions such as ischaemic heart disease that reduce cardiac output
Heat exhaustion	Characterised by volume and salt depletion. It is an inability to continue an activity due to heat stress. It presents with thirst, lethargy, headache, nausea but importantly a normal mental status. Some literature describes it as benign as it may be protective in the development of heat stroke, causing an individual to stop an activity and thus the generation of heat
Heat stroke	Neurological impairment with core body temperature $\geq 40^{\circ}\text{C}$ (rectal temperature is gold standard in a pre-hospital environment). Symptoms can involve a coarse muscle tremor, confusion, aggression and loss of consciousness. Sweating may be absent due to dehydration and failure of thermoregulatory mechanisms

with increased incidence seen at the extremes of age, due to sub-optimal homeostatic thermoregulation. Peaks of incidence are common during heatwaves, exemplified by the 70 000 heat-related deaths reported during the 2003 European heatwave. Conversely, exertional heat illness predominantly affects young, physically fit individuals (such as soldiers and athletes), reflecting a failure to dissipate intrinsic heat production from physical activity.

Risk factors for the development of heat illness are well established (Box 12.6).

### Pathophysiology of heat stroke

The pathophysiology of heat stroke can be summarised as organ dysfunction from the high temperature itself, and end-organ ischaemia from diminished blood flow. Increased sweating results in dehydration and blood pools in vasodilated peripheral vasculature resulting in a decreased effective blood volume. The blood viscosity increases resulting in heart strain. Enzymes denature at 40 °C and at 41 °C mitochondrial activity stops; the subsequent loss of oxidative phosphorylation results in organ ischaemia. The muscles and gastrointestinal tract are affected first, followed by the central nervous system, circulatory and clotting systems. The pathophysiology is similar to sepsis, severe trauma and extensive burns (Box 12.7).

### Management

Mortality of heat illness is around 30% and is directly proportional to the duration and magnitude of hyperthermia, therefore immediate cooling should begin at the scene, before transfer to hospital. The aim should be to reduce core temperature to approximately 39 °C.

12.6 Risk factors for the development of heat-related illness	
Risk factor	Mechanism
High ambient temperatures	Increased radiant heat gain
High humidity	Ineffective evaporative heat loss at humidities > 75%
Little shade	Increased radiant heat gain
Intercurrent illness	Raised core temperature
Extremes of age	Suboptimal homeostatic thermoregulation
Overweight/unfit	The main identifiable risk factor for heat illness during military training was a body mass index (BMI) $\geq 30$ kg/m <sup>2</sup>
Effects of alcohol and medication (diuretics, ACE inhibitors, $\beta$ -adrenoceptor antagonists, vasodilators, antidepressants, anticholinergics, antihistamines and stimulants)	Either through dehydration, decreased cardiovascular and peripheral response to dissipate heat, reduced sweating or increased metabolic rate
Inappropriate clothing	Reduced heat loss through combination of radiation, convection and evaporation
Dehydration	Regardless of body habitus or fitness level, fluid losses that result in a 2%–3% decrease in body weight correlate with decreased aerobic performance, increased perception of fatigue, and greater core temperatures at a given workload
Previous heat-related illness	Impaired homeostatic thermoregulation
No acclimatisation	Body fluid deficits are reduced by around 30% in acclimatised individuals, despite increased sweat rates of up to 18%, as a result of a more accurate thirst response
Intense work/duration	Increased heat generation

A patient should be removed from the heat source and put into shade to reduce radiant heat gain. Resting in an air-conditioned room has cooling rates of 0.03–0.06 °C/min. Clothes should be removed, high-flow oxygen administered, intravenous access established and a rectal temperature taken. If temperature measurement is unavailable but the history and clinical findings are consistent with heat illness, initiation of treatment with cooling techniques should not be delayed.

A number of cooling strategies exist (Box 12.8), and their implementation will depend on what is feasible within each particular environment. Two meta-analyses have concluded that ice water immersion is the most effective treatment strategy with cooling rates of 0.20–0.35 °C/min for iced water and 0.11 °C/min for wet towels. Immersion is unlikely to be feasible in the wilderness environment and many hospitals, with further consideration of the potential dangers of immersing a patient with a reduced conscious level. Immersing the hands and forearms in cold water results in reduction of heat stress in normal subjects, but has not been evaluated in the treatment of heat stroke patients.

The placement of ice/cold packs in the axillae, groin and neck has been recommended as an easy method to use in the field, but when compared with evaporative cooling in healthy subjects, cooling times were longest when the ice packs were used alone and shortest when both methods were used simultaneously. Evaporative cooling involves the removal of clothing, spraying tepid or cool water over the patient, and facilitating evaporation and convection with the use of a fan.

The role of invasive cooling methods such as gastric, bladder or peritoneal lavage has not been fully established. Neither hyperhydration nor dantrolene (used in the treatment of malignant hyperthermia) have

12.7 Pathophysiology of heat stroke	
	Increased heart rate and an increase in cardiac output by 3L/min for each 1 °C rise in core temperature. Increased peripheral blood flow from 0.2L/min up to 8L/min. Dehydration with sweat rates increasing from 0.5L/day up to 15L/day. Risk of heart failure if pre-existing cardiac disease
	Ischaemia and cerebral oedema due to the high temperature itself and vascular endothelial damage
	Intestinal mucosal impairment results in toxins entering the portal vein and circulating systemically resulting in sepsis
	Tachypnoea and pulmonary vasodilatation result in acute respiratory distress syndrome (ARDS) (p. 201)
	Acute renal failure due to ischaemia, dehydration and rhabdomyolysis (p. 198)
	Acute liver injury from ischaemia and high levels of circulating inflammatory cytokines (p. 879)
	Microthrombus formation causing further ischaemia and disseminated intravascular coagulation (p. 988)
	Multiple electrolyte abnormalities including hypokalaemia, hypomagnesaemia, hypoglycaemia and metabolic acidosis

## i

## 12.8 Summary of cooling rates

Cooling technique (target < 39°C)	Cooling rate
Ice water immersion	0.20–0.35°C/min
Wet towels	0.11°C/min
Evaporative and convective combined	0.034–0.31°C/min
Air-conditioned room	0.03–0.06°C/min
Intravenous cold saline	0.03°C/min
Intravenous room-temperature saline	0.015°C/min

## i

## 12.9 Wet Bulb Globe Temperature (WBGT)

Meteorological conditions affect environmental temperatures and a widely used index to calculate this is the WBGT, originally developed by the US Marines. WBGT is an apparent temperature measurement taking into account temperature, humidity, wind speed and solar radiation. This gives a much more accurate representation of the degree of heat stress experienced. WBGT is used to formulate a set of guidelines that guide activity levels, hydration and rest periods. For example, a 'do not start' WBGT of 21°C has been suggested for American marathons based on an unsuccessful attempt of 160 per 1000 finishers above this level, although the incidence of heat-related illness is not well described.

evidence of benefit. Cold intravenous fluids may supplement cooling. In a study of healthy volunteers, infusion of 4°C saline over 30 minutes cooled the body by 1°C, compared to 0.5°C with room-temperature saline.

### Prevention

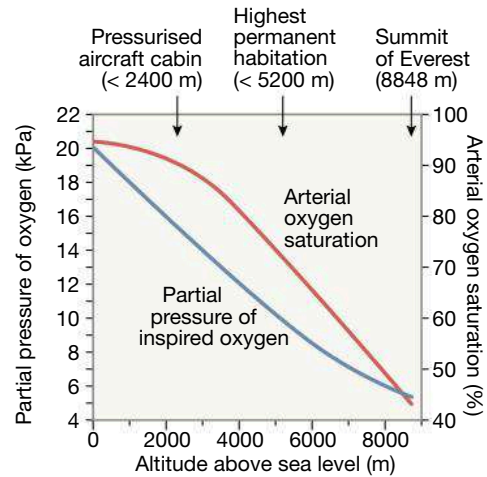

Cooling in a wilderness setting may be incredibly challenging, with likely no access to ice or cold fluids. Prevention of heat illness is therefore paramount. Strategies include:

1. Ensuring adequate hydration. The 2019 Wilderness Medical Society heat illness guidelines identify hydration as the 'most readily modifiable physiologic risk factor'. Fluid ingestion is also identified as the most effective approach to mitigate the rise in core temperature amongst athletes. Military guidelines recommend a 0.25–1.25L/hr hydration strategy that varies for work rates (low/medium/high/very high) at a given Wet Bulb Globe Temperature (WBGT) (Box 12.9).
2. Consider accepted WBGT cut-offs for activities (Box 12.9).
3. Expedition participants should receive high-level education pre-departure on the dangers of heat-related illness with evidence-based advice on risk reduction. Increased hydration and cooling strategies have been documented following educational material targeting older people prior to heatwaves.
4. If possible, implementing a period of acclimatisation with at least 1–2 hours of mild exertion in a hot environment for at least 8 days. Body fluid deficits are reduced by around 30% in acclimatised individuals as a result of a more accurate thirst response.

## Acute high altitude illness

Illness due to high altitudes represents over a quarter of all serious medical incidents from reviews of expeditions in a range of environments. High altitude is generally considered to be over 2500m and extreme altitude over 5500m. The summit of Mount Everest stands at 8848m, where the barometric pressure and atmospheric partial pressure of oxygen ( $PO_2$ ) is around one-third of that at sea level; the percentage of oxygen remains the same at 20.9%.

Unconsciousness secondary to hypoxia normally occurs within 3 minutes if the body is exposed to an altitude over 8000m. However, with a

**Fig. 12.4** Change in inspired oxygen tension and blood oxygen saturation at altitude. The blue curve shows changes in oxygen availability at altitude and the red curve shows the typical resultant changes in arterial oxygen saturation in a healthy person. Oxygen saturation varies between individuals according to the shape of the oxygen–haemoglobin dissociation curve and the ventilatory response to hypoxaemia. (To convert kPa to mmHg, multiply by 7.5.)

period of acclimatisation, the body is able to adapt and overcome even profound hypoxaemia with arterial partial pressures of oxygen ( $PaO_2$ ) of 2.55 kPa recorded at 8400m in a healthy climber (normally > 10.6 kPa at sea level).

## Physiological effects of high altitude

There are a number of physiological systems affected by altitude.

### Respiratory

Reduction in oxygen tension results in a fall in arterial oxygen saturation (Fig. 12.4). This varies widely between individuals, depending on the shape of the sigmoid oxygen–haemoglobin dissociation curve (see Fig. 25.5) and the ventilatory response. Alveolar ventilation increases with altitude, lowering carbon dioxide and resulting in a respiratory alkalosis, with metabolic compensation via renal bicarbonate loss. At high altitude, individuals are at the steep section of the oxygen dissociation curve whereby a small fall in  $PaO_2$  can result in a substantial decrease in oxygen saturation. The initial respiratory alkalosis shifts the curve to the left but with a period of acclimatisation, increased production of 2,3-diphosphoglycerate moves the curve rightwards towards a sea-level position.

### Haematological

Measured haemoglobin concentration increases with acclimatisation – a 20% fall in plasma volume causes haemoconcentration and erythropoietin release (stimulated by hypoxia) leads to increased production of haemoglobin.

### Cardiovascular

There is an initial increase in cardiac output due to increased sympathetic activity and heart rate. The reduction in plasma volume causes a fall in preload and stroke volume. Cardiac output returns to baseline over several weeks but the stroke volume remains lowered.

## Illness at high altitude

Neurological and respiratory complications from high altitude occur in individuals who ascend rapidly and are not acclimatised. Acute mountain sickness (AMS) is seen in over a third of people who ascend to 3000m. Serious illness includes high altitude pulmonary oedema (HAPE) and

high altitude cerebral oedema (HACE), occurring in 0.1–4% of people climbing over 4000m. Prevention is essential and achievable through controlled ascents.

### Acute mountain sickness

AMS is a syndrome comprised principally of non-specific symptoms including headache, fatigue, anorexia, nausea and vomiting, insomnia and dizziness. The pathophysiology of AMS is not fully understood but it is thought that hypoxia results in vasodilation and increased capillary hydrostatic pressure causing a fluid leak and a raised intracranial venous volume with risk of raised intracranial pressure. There is believed to be an increase in CSF production with a reduced buffering capacity. Non-acclimatised individuals show impaired gas exchange and a lower degree of hyperventilation, alongside fluid retention and a heightened sympathetic activation. Symptoms can occur within 4 hours, with the diagnostic definition specifying an ascent to >2500m within the prior 4 days. The symptoms can vary in severity, from trivial to completely incapacitating.

#### Management

Treatment of mild cases consists of rest and symptomatic control with simple analgesia; symptoms usually resolve after 1–3 days at a stable altitude, but may recur with further ascent. Occasionally there is progression to cerebral oedema (HACE). Persistent symptoms indicate the need to descend, which is considered the definitive treatment.

Medication options include acetazolamide and dexamethasone. Acetazolamide is used in both the prophylaxis of AMS and as a treatment option. It works as a carbonic anhydrase inhibitor in the kidneys, increasing bicarbonate excretion and inducing a metabolic acidosis, thereby offsetting the hyperventilation-induced alkalosis seen at altitude. It also decreases CSF production, reducing intracranial pressure and risk of progression to HACE. Ideal dosing strategies are debated, however 125 mg twice daily may be used as prophylaxis and 250 mg three times daily for treatment. Higher doses (750 mg) have greater efficacy but also increased side-effects. Dexamethasone (8 mg) moderates capillary leak and reduces the inflammatory response, improving symptoms to allow for a safe descent.

### High altitude cerebral oedema

HACE is considered a severe sequela of AMS, presenting as ataxia or cognitive impairment in addition to the symptoms described above. It very rarely occurs without being preceded by milder AMS symptoms, making early recognition and treatment of AMS essential. Untreated HACE can progress to coma within 24 hours.

#### Management

Management is directed at improving oxygenation. Descent is essential and dexamethasone (8 mg immediately, followed by 4 mg four times daily) should be given. If descent is impossible, descent can be simulated with the use of portable hyperbaric chambers, such as a Gamow bag. Use of these devices, however, can be difficult in patients with vomiting or a reduced level of consciousness.

### High altitude pulmonary oedema

HAPE is a life-threatening condition that usually occurs in the first 4 days after ascent above 2500m and is the leading cause of mortality from high altitude illness. It is defined as an imbalance of hydrostatic pressure within the alveoli with no evidence of inflammatory changes. Hypoxic pulmonary vasoconstriction causes alveolar capillary stress failure and subsequent pulmonary hypertension. This results in capillary fluid leak which is exacerbated by exercise and compounded by impaired epithelial sodium transport, normally essential for fluid reabsorption. Initial symptoms include a dry cough, exertional dyspnoea and extreme fatigue. Later, the cough becomes wet with haemoptysis and orthopnoea. Tachycardia

and tachypnoea occur at rest and crepitations may often be heard in both lung fields. Fever may also be present. There may be profound hypoxaemia and radiological evidence of diffuse alveolar oedema. HAPE may occur without the preceding signs of AMS, although around 50% of patients with HAPE have concurrent AMS and 14% have HACE.

#### Management

Treatment is directed at reversal of hypoxia, with immediate descent (by a minimum of 1000m) and oxygen administration targeting saturations >90%. A portable hyperbaric chamber should be used if descent is delayed. Nifedipine (60mg modified release divided into 2–3 doses) is recommended prophylactically, starting 1 day before attempting ascent above 2500m and continued for a further 5 days at altitude or until descent below 2500m. For treatment of HAPE there is no evidence of benefit for any pharmacological therapy compared to descent and oxygen.

## Subaquatic medicine

### Drowning

12

Drowning remains a leading cause of death globally and is defined as 'the process of experiencing respiratory impairment from submersion/immersion in liquid'. Immersion refers to the upper airway being above the water surface and submersion below it. The drowning process involves initial breath holding, followed by a period of laryngospasm. Gas exchange is prevented resulting in hypoxia, hypercarbia and acidosis. Respiratory movements are stimulated by the respiratory centre due to hypercarbia, however the laryngospasm results in obstruction of the airway. The laryngospasm eventually falters with continued hypoxia resulting in the aspiration of liquid of a variable amount, usually <4mL/kg.

Aspiration of either saltwater or freshwater results in changes to the alveolar surfactant and the alveolar capillary barrier causing atelectasis, ventilation–perfusion mismatch and hypoxia. Saltwater is hypertonic resulting in bronchoconstriction, inflammation and pulmonary oedema; aspiration of 2.5mL/kg of seawater results in a 75% increase in right-to-left shunting of deoxygenated blood. Fresh water is hypotonic and is generally absorbed through the pulmonary circulation, entering the systemic circulation and damaging the alveolar capillary membrane. This can also generate foam which further decreases ventilation efficiency. The clinical significance of swallowing water into the stomach during the drowning process remains unclear. Clinically significant electrolyte abnormalities from aspiration and swallowing of both hypotonic and hypertonic fluids are uncommon requiring >22mL/kg of fluid, although both hyper- and hyponatraemia have been described.

The majority of drownings occur in cold water that results in body cooling, water being considered thermoneutral at around 35°C. Skin cooling (cold shock) and tissue cooling (hypothermia) are important factors in drowning. The historical term 'dry-drowning' refers to the 10% of drowning cases that are documented to have 'macroscopically dry lungs' on examination, attributed to laryngospasm from water irritation on contact. This remains controversial but is no longer felt to be true, with newer evidence demonstrating the presence of microscopic liquid in the lungs of all drowned patients. 'Secondary drowning', referring to patients who develop acute respiratory distress syndrome (ARDS), is now also considered a misnomer as there is no second submersion and ARDS is a recognised complication of the drowning process.

#### Cold shock

The cold shock response is believed to be responsible for the majority of drowning deaths. Sudden cold-water immersion results in an uncontrolled reflex inspiratory gasping, hyperventilation with profound hypocapnia and tachycardia from activation of peripheral sub-epidermal cold receptors. There is a 75% reduction in breath hold time, which can therefore result in the aspiration of water. The response is maximal

at water temperatures of 10–15°C and peaks within the first 30 seconds of immersion, waning over 2–3 minutes. Continued immersion then results in physical incapacitation from neuromuscular cooling, with peripheral paralysis occurring at regional limb temperatures of 5–15°C. Hypothermia develops after around 30 minutes in cold water.

### Autonomic conflict

Simultaneous positive and negative chronotropic triggers are considered arrhythmogenic. Bradycardia from vagal stimulation (initiated when face down in water – dive reflex) coupled with a tachycardia from sympathetic activation (cold, stress or exercise) can generate arrhythmias in previously healthy individuals and can be fatal in those with structural cardiac abnormalities.

### Pre-hospital management

In-water CPR and rescue breaths are no longer recommended. In-water rescue is not recommended for untrained individuals – remember 'Reach, Throw, Row, Don't Go'. If extracting someone from the water following prolonged immersion, the patient should be kept horizontal to prevent post-immersion hypotension; the loss of hydrostatic pressure that the water was applying can result in venous pooling and a sudden circulatory collapse. The patient should be kept warm, with life support commenced at the earliest opportunity. Cervical spine precautions should be considered as there may be a traumatic precursor to the drowning incident (e.g. tombstoning), although these injuries are uncommon (0.5% of cases). Postural drainage techniques to try to clear fluid from the lungs have no proven benefit.

### In-hospital management

Treatment is often focused on re-warming and organ support including non-invasive ventilation (CPAP) and protective lung ventilation strategies for acute lung injury/ARDS. Prolonged immersion can result in hypovolaemia due to the hydrostatic pressure effect of water and the patient may require IV fluid. Prophylactic antibiotics are not recommended unless submersion was in grossly contaminated water. Asymptomatic patients, with no respiratory compromise, a normal chest X-ray and normal arterial blood gas can be discharged home after 6–8 hours' observation.

### CPR modifications

Five initial rescue ventilations are recommended given the hypoxic nature of a cardiac arrest in drowning. The patient's chest should be dried before application of defibrillation pads; however less than 5% of drowned patients are in a shockable rhythm. The common progression of cardiac rhythm is from bradycardia, to pulseless electrical activity, to asystole. Submersion in ice-cold water (less than 6°C) may confer improved survival due to neuroprotection from rapid brain cooling before the onset of severe hypoxia; children in particular appear to have greater protection, believed in part to be due to a greater surface area to mass ratio allowing quicker cooling. For submersion times greater than 30 minutes in water warmer than 6°C, resuscitation is likely to be futile. If water temperature is below 6°C resuscitation is likely to be futile following a submersion over 90 minutes long. Submersion within a vehicle may prolong these times due to the potential presence of an air bubble. International guidelines do vary on the futility associated with submersion duration. The overall mortality of drowned patients who present in cardiac arrest is 93%.

## Decompression illness

Changes in environmental pressure (as seen in diving) can result in decompression illness due to intravascular or extravascular bubbles, the clinical manifestations of which include both arterial gas embolism and decompression sickness. Diagnosis of decompression illness is based on the history and clinical features in patients following a dive; 90% of cases are symptomatic within 6 hours, however, delays up to 72 hours are described.

A brief review of the physics and physiology of diving is essential in understanding the medical issues encountered. The two most important gas laws are Boyle's law and Henry's law (Fig. 12.5).

### Decompression sickness

Nitrogen bubble formation on ascent can cause direct mechanical damage to the vascular endothelium and an inflammatory response. The bubbles occur almost anywhere in the body; therefore, the clinical presentation is broad ranging from malaise and headache to paraesthesiae, lymphoedema, rash, joint pain and neurological manifestations including ataxia, paralysis and altered mentation. The overall incidence is low (0.03%) for recreational divers. Decompression sickness is very uncommon for diving depths less than 10m and is normally seen following multiple dives.

#### A Boyle's law

Depth in metres	Pressure in atmospheres	Volume of a sealed container	Lung volume
0	1	1 	6L 
10	2	1/2 	3L 
20	3	1/3 	2L 
30	4	1/4 	1.5L 
40	5	1/5 	1.2L 

#### B Henry's law

**Fig. 12.5 Boyle's law and Henry's law.** **A** Boyle's law: The volume of a gas is inversely proportional to the pressure. Atmospheric pressure increases with depth, increasing by 1 atmosphere for each 10m of depth in water. During diving this increasing pressure compresses the gas within the human body, including the lungs, ears, sinuses and bowels. During ascent this gas expands and can cause barotrauma if the ascent is too rapid. **B** Henry's law: The amount of gas that dissolves in a liquid is proportional to the partial pressure of the gas. Nitrogen is not metabolised by the body and increasingly dissolves into the blood on descent. The reverse occurs on ascent, which if ascending too quickly can cause bubbles to form, resulting in decompression sickness.

### Arterial gas embolism

Expanding gases during ascent from diving, from depths as little as 1 metre, can rupture the alveolar capillary membrane (barotrauma), introducing alveolar gas into the arterial circulation. The brain is the most commonly affected organ. Small venous gas emboli are common with diving and usually are of no clinical consequence due to pulmonary capillary filtering. A patent foramen ovale is seen in around a quarter of the population which can result in these emboli transferring to the arterial circulation, causing neurological sequelae. Overall, the risk of arterial gas embolism is rare, representing only around 4% of documented decompression illnesses. Risks include rapid ascents, breath holding and pre-existing pulmonary disease. If there is rapid onset of neurological signs, including seizures or a reduced consciousness following ascent, arterial gas embolism should be suspected.

### Management

Any obtunded patient should have appropriate first aid. Definitive treatment for decompression illness is providing 100% oxygen to wash out gas from the tissues to the lungs and remove bubbles. This should be instigated for all patients regardless of their oxygen saturations.

Chamber recompression is the gold standard therapy and should be performed as soon as possible causing a theoretical crushing of bubbles (as per Boyle's law) and providing improved oxygenation to damaged tissues. Extraction to a recompression chamber may require aeromedical retrieval and helicopters at low altitude (less than 300m) or those with cabins pressurised to 1 atmosphere are recommended. In-water recompression is controversial and is recommended only for divers, including the patient, with specific training in decompression procedures underwater. Previous recommendations of a head-down position to stop cranial spread of bubbles is no longer recommended due to the increased risk of cerebral oedema; patients should be kept horizontal. One litre of intravenous fluid should be given to correct the intravascular fluid loss from endothelial bubble injury and dehydration associated with immersion. Analgesia should be avoided; non-steroidal anti-inflammatory drugs can result in haemorrhage whilst opiates raise the risk of oxygen toxicity. The Divers Alert Network can be contacted for international advice and support.

### Immersion pulmonary oedema

Immersion pulmonary oedema can affect surface swimmers as well as divers and is believed to be a leading cause of death during the swim stage of triathlons, previously felt to be due to drowning. Immersion results in exposure to hydrostatic pressure which collapses veins and redistributes blood to the thorax, causing increased preload, cardiac contractility and stroke volume. Rising pulmonary alveolar capillary pressure results in a fluid shift into the lung interstitium initially, followed

by the alveoli. This is normally balanced by the release of natriuretic peptides (ANP and BNP) causing a natriuresis and diuresis, however in immersion pulmonary oedema this compensation is overwhelmed. Risk factors include overhydration, overexertion, heart disease, hypertension and cold water, all resulting in raised ventricular filling pressures. Breathing into a snorkel or scuba equipment can result in higher negative pressures in the alveoli with a subsequent greater fluid transudation into them (the opposite of positive pressure ventilation used to treat pulmonary oedema). Symptoms range from shortness of breath to haemoptysis and frothy sputum, generally occurring within 10 minutes of starting swimming, and of variable onset with diving. Treatment involves extraction from the water to remove the hydrostatic pressure, which in turn decreases ventricular filling pressures. Patients should be kept warm to prevent vasoconstriction, sat upright and given 100% oxygen. In-hospital management involves a combination of vasodilators (nitrates), diuretics and positive-pressure ventilation (CPAP). Recurrence rates are around 30%.

### Shallow-water blackout

This condition refers to the loss of consciousness underwater when hyperventilation is followed by breath holding. It generally occurs in water less than 5m in depth and can affect even experienced swimmers. Hyperventilation (as rapid shallow breaths before diving) preceding a breath hold lowers the arterial CO<sub>2</sub> and delays the hypercarbic stimulus to breathe, which may not occur before hypoxaemia and unconsciousness develop. Unconsciousness usually occurs on ascent as the hydrostatic pressure decreases, reducing the thoracic shunting of blood and gas exchange, coupled with a decreasing partial pressure of oxygen (Boyle's law) and resulting in a significant hypoxaemia.

## Multiple Choice Questions

12.1 You are part of a search and rescue team looking for a trapped skier, following an avalanche 20 minutes prior. On finding the patient you are instructed by the team leader to move them very carefully, to not induce a cardiac arrhythmia. Below what core temperature can ventricular fibrillation be induced from excessive movement?

- A. 36°C
- B. 32°C
- C. 35°C
- D. 30°C
- E. 33°C

Answer: D.

As the core temperature falls there is a reduction in cardiac output with initial maintenance of stroke volume. At around 28°C the heart rate is reduced by 50%. Initial conduction abnormalities include a sinus bradycardia, progressing to slow atrial fibrillation (AF) and then to ventricular fibrillation (VF). VF may be induced below 30°C with excessive stimulation/movement, which is why handling of hypothermic patients needs to be performed with great care.

12.2 You are working as a medic for a 100-mile ultramarathon, environmental conditions are wet (moderate rain), with a temperature of 8°C. You are asked to see a competitor who has come into the medical tent after 12 hours of running. The competitor is drowsy, confused and is not shivering. Blood sugar is normal. You do not have access to a rectal thermometer. Using the Swiss Staging System, quantify the possible degree of hypothermia for this patient.

- A. <24°C
- B. 28–31°C
- C. 24–27°C
- D. 32–35°C
- E. 35–36°C

Answer: B.

Traditionally, hypothermia is categorised as mild (32–35°C), moderate (28–32°C) and severe (<28°C), however newer staging systems, such as the Swiss Staging System, adopted by some ambulance services, define the level of hypothermia based on symptoms (see Fig. 12.3). This has been shown to overestimate the degree of hypothermia in around 20% of cases but remains a helpful classification when an accurate core temperature cannot be obtained.

12.3 Which of the following statements is true for adaptations to resuscitation algorithms for hypothermic patients in cardiac arrest?

- A. Withhold all shocks – chance of shockable rhythm <5%
- B. Signs of life should be checked for 30 seconds rather than 10 seconds
- C. Do not warm hypothermic patients in cardiac arrest – the hypothermia is neuroprotective
- D. Withhold medications (adrenaline, amiodarone etc.) until core temperature >30°C and double the interval time between doses between core temperatures of 30°C and 35°C
- E. A potassium level of 7 mmol/L is diagnostic of resuscitation futility

Answer: D.

There are a number of adaptations to resuscitation algorithms for hypothermic patients in cardiac arrest. Assessment for signs of life should be extended to 1 minute. Ventricular fibrillation and ventricular tachycardia can be defibrillated, however if after three shocks there is no response, additional shocks should be delayed until core temperature is greater than 30°C. Stacked shocks are not recommended. Withhold adjunctive medications (adrenaline, amiodarone, etc.) if the patient is below 30°C, and double the interval time between doses between 30°C and 35°C.

Markers of futility include: obvious lethal injury, prolonged asphyxia (mouthful of snow etc.), incompressible thorax (distinct from a stiff chest which is common), frozen abdomen, or potassium >12 mmol/L.

12.4 With regards to freezing cold injury (frostbite), which of the following statements around management is correct?

- A. The affected area should always be rewarmed immediately in the pre-hospital environment
- B. Early amputation is the gold standard therapy
- C. Rubbing of the area with direct application of heat pads to thaw the affected region is recommended
- D. Analgesia is not required, freezing injuries are not painful
- E. Aspirin 75–300 mg and ibuprofen 800 mg are recommended

Answer: E.

If concerned about the possibility of cold injury, immediate pre-hospital treatment is to try to shelter from the environment, consume warm drinks, remove shoes, wet clothing and jewellery and re-dress in warm, dry clothing. If there is absolutely no risk of re-freezing then warming the area can be achieved by placing the area into a companion's armpit or groin. Aspirin 75–300 mg and ibuprofen 800 mg are recommended. Do not rub the area and do not place heat sources directly onto the area. Evacuation for formal medical review should be obtained. Warmed areas need to be made non-load-bearing and therefore prior thought about extraction needs to be considered. Aloe vera gel has anti-prostaglandin effects and can be applied before application of a non-adherent dressing, splinting and elevation of the affected region.

Definitive warming involves placing the affected area into circulating water between 37°C and 42°C with small amounts of antiseptic for around an hour, avoiding contact with the sides of the container. Additional treatment involves fluid replacement with warmed fluids (due to cold diuresis), strong analgesia and blister care. Blisters may present as clear, cloudy or haemorrhagic. Blister management remains controversial, with current evidence recommending débridement of all blisters in hospital (likely under a general anaesthetic), to improve wound healing. There is no evidence for prophylactic antibiotics and tetanus should be given following local protocols; frostbite wounds are not considered tetanus-prone.

12.5 The most readily modifiable physiological risk factor for the development of heat illness is:

- A. Obesity
- B. Hydration
- C. Acclimatisation
- D. Use of beta-blockers
- E. Aerobic fitness

Answer: B.

The 2019 Wilderness Medical Society heat illness guidelines identify hydration as the 'most readily modifiable physiologic risk factor'. Fluid

ingestion is also identified as the most effective approach to mitigate the rise in core temperature amongst athletes. Military guidelines recommend a 0.25L/hr – 1.25L/hr hydration strategy that varies for work rates (low/medium/high/very high) at a given Wet Bulb Globe Temperature (WBGT).

12.6 The definition of heat stroke is:

- A. Mild swelling to the limbs during the first few days of heat exposure due to increased plasma volume
- B. Neurological impairment with core body temperature  $\geq 40^{\circ}\text{C}$
- C. A transient loss of consciousness in the context of heat exposure with a relatively rapid return to normal function and baseline
- D. It is an inability to continue an activity due to heat stress
- E. Body spasms related to sodium loss

Answer: B.

Heat-related illness defines a spectrum of pathology from benign heat oedema to lethal heat stroke. The definition of heat stroke is: neurological impairment with core body temperature  $\geq 40^{\circ}\text{C}$  (rectal temperature is gold standard in a pre-hospital environment). Symptoms can involve a coarse muscle tremor, confusion, aggression and loss of consciousness. Sweating may be absent due to dehydration and failure of thermoregulatory mechanisms.

12.7 You are working on an expedition in the Costa Rican jungle. The expedition leader asks you theoretically what the best cooling strategy is for patients with heat stroke. In your current location you only have access to cold water. You suggest:

- A. Removing the patient into the shade
- B. Calling for a helicopter to use the downwash from the blades
- C. Forcing the patient to drink cold water
- D. Spraying the patient with cool water and using a combination of evaporative and convective heat loss
- E. Ice water immersion.

Answer: D.

A number of cooling strategies exist and their implementation will depend on what is feasible within each particular environment. Two meta-analyses have concluded that ice water immersion is the most effective treatment strategy, with cooling rates of  $0.20^{\circ}\text{C} - 0.35^{\circ}\text{C}/\text{min}$  for iced water and  $0.11^{\circ}\text{C}/\text{min}$  for wet towels. Immersion is unlikely to be feasible in the wilderness environment and in many hospitals, with further consideration for the dangers of potentially immersing a patient with a reduced conscious level.

The placement of ice/cold packs in the axillae, groin and neck has been recommended as an easy method to use in the field, but when compared with evaporative cooling in five healthy subjects, cooling times were longest when the ice packs were used alone and shortest when both methods were used simultaneously. Evaporative cooling involves the removal of clothing, spraying tepid or cool water over the patient, and facilitating evaporation and convection with the use of a fan.

12.8 You are working on an expedition on Mont Blanc and are asked to see a patient who at 3500m has developed a wet cough with frothy sputum. The patient is tachycardic with a high respiratory rate and you hear bibasal crepitations in both lungs. The patient insists they have mild acute mountain sickness, which they have had previously, and wants to continue to summit. They have taken no prophylactic medications. What is the most appropriate plan?

- A. The patient likely has high altitude pulmonary oedema and should immediately descend by at least 1000m alongside giving high-flow oxygen

- B. The patient is most likely correct and has mild acute mountain sickness and should be allowed to summit
- C. The patient has high altitude cerebral oedema and should be given 8 mg of dexamethasone and then start to descend
- D. The patient has no evidence of high altitude illness, and the findings are consistent with normal physiological changes at altitude. No action is required
- E. The patient has severe acute mountain sickness and should remain at their current altitude for 2–3 days

Answer: A.

HAPE is a life-threatening condition that usually occurs in the first 4 days after ascent above 2500m and is the leading cause of mortality from high altitude illness. Hypoxic pulmonary vasoconstriction causes alveolar capillary stress failure and subsequent pulmonary hypertension. This results in capillary fluid leak which is exacerbated by exercise and compounded by impaired epithelial sodium transport, normally essential for fluid reabsorption. Initial symptoms include a dry cough, exertional dyspnoea and extreme fatigue. Later, the cough becomes wet with haemoptysis and orthopnoea. Tachycardia and tachypnoea occur at rest and crepitations may often be heard in both lung fields. Fever may also be present. There may be profound hypoxaemia and radiological evidence of diffuse alveolar oedema. HAPE may occur without the preceding signs of AMS, although around 50% of patients with HAPE have concurrent AMS and 14% have HACE.

Treatment is directed at reversal of hypoxia, with immediate descent (by a minimum of 1000m) and oxygen administration targeting saturations  $> 90\%$ . A portable hyperbaric chamber should be used if descent is delayed. Prophylactically, nifedipine (60mg modified release divided into 2–3 doses) should be given to reduce pulmonary arterial pressure, ideally 1 day preceding ascent and continued for a further 5 days.

12.9 You are working in an Emergency Department and are asked to review a 17-year-old male patient who 1-hour prior aspirated some water whilst swimming in the sea and was rescued by members of the public who described initial panicking and respiratory impairment. The patient appears well, with normal observations. The most appropriate plan is:

- A. The patient is suitable for discharge with no evidence of ongoing respiratory distress
- B. The patient is suitable for discharge following a normal chest X-ray
- C. The patient is suitable for discharge following 6–8 hours' observation if his observations remain normal, with a normal chest X-ray  $\pm$  normal arterial blood gas
- D. The patient should be admitted for 72 hours to observe for delayed acute respiratory distress syndrome (ARDS)
- E. The patient does not need to be seen in an Emergency Department and should be discharged home without review

Answer: C.

Drowning is defined as 'the process of experiencing respiratory impairment from submersion/immersion in liquid'. Asymptomatic patients, with no respiratory compromise, a normal chest X-ray and normal arterial blood gas can be discharged home after 6–8 hours' observation.

12.10 You are on holiday on a beach and see a 50-year-old female swimmer in difficulty. She is dragged from the water by a first aider on scene and is currently lying on her back in the shallow water with small waves breaking over her. She is alert but is coughing frequently, with a fast respiratory rate. The first aider does not wish to move the patient due to the risk of a cervical spine injury. The most appropriate plan is:

- A. Assist the first aider by applying cervical spine immobilisation and wait for an ambulance to arrive with a scoop

- B. Drag the patient up the beach out of the water to prevent further aspiration or development of hypothermia
- C. Acknowledge the first aider's concern, but reassure that the risks are low (0.5%) for a cervical injury and it would be safest to ask the patient to move with help up the beach
- D. Do nothing, the patient is clearly alert and breathing and no further intervention is required
- E. Administer 5 rescue breaths, followed by raising the patient's body above their head to allow for postural drainage of water from the lungs

Answer: C.

The safest option is to remove the patient from the water due to the ongoing risk of further aspiration and ongoing cooling with subsequent hypothermia. Risk of cervical spine injury is low (0.5%). Asking the patient if they are able to move up the beach with support is the most appropriate initial step. Postural drainage techniques are not recommended, with no evidence of benefit.

- Trematodes (flukes) 338
- Cestodes (tapeworms) 340

### Ectoparasites 342

### Fungal infections 342

- Superficial mycoses 343
- Subcutaneous mycoses 344
- Systemic mycoses 344

## Clinical examination of patients with infectious disease

### 5 Eyes

Conjunctival petechiae  
Painful red eye in uveitis  
Loss of red reflex in endophthalmitis  
Roth spots in infective endocarditis  
Haemorrhages and exudates of cytomegalovirus retinitis  
Choroidal lesions of tuberculosis

Roth spots in endocarditis

### 4 Head and neck

Lymphadenopathy  
Parotidomegaly  
Abnormal tympanic membranes

### 3 Oropharynx

Dental caries  
Tonsillar enlargement or exudate  
Candidiasis

▲ Streptococcal tonsillitis

### 2 Hands and nails

Finger clubbing  
Splinter haemorrhages  
Janeway lesions  
Signs of chronic liver disease  
Vasculitis lesions

▲ Splinter haemorrhages in endocarditis

### 1 Skin

Generalised erythema  
Rash (see opposite)  
IV injection track marks  
Surgical scars  
Prosthetic devices, e.g. central venous catheters  
Tattoos

### Observation

- Temperature
- Sweating
- Weight loss
- Respiratory distress
- Altered consciousness
- Pallor
- Jaundice

### 6 Neurological

Neck stiffness  
Photophobia  
Delirium  
Focal neurological signs

### 7 Heart and lungs

Tachycardia, hypotension  
Murmurs or prosthetic heart sounds  
Pericardial rub  
Signs of consolidation  
Pleural or pericardial effusion

▲ Chest X-ray consolidation in pneumonia

### 8 Abdomen

Hepatosplenomegaly  
Ascites  
Renal angle tenderness  
Localised tenderness or guarding with decreased bowel sounds, e.g. in left iliac fossa with diverticulitis  
Mass lesions  
Surgical drains

### 9 Musculoskeletal

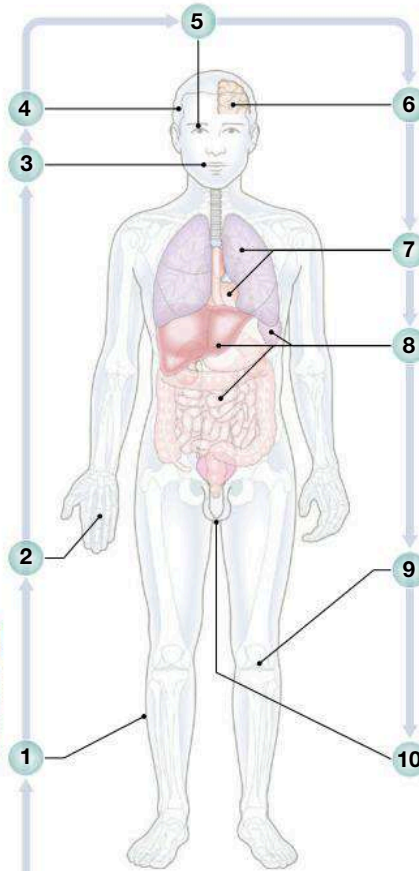

Joint swelling, erythema or tenderness  
Localised tender spine suggestive of epidural abscesses or discitis  
Draining sinus of chronic osteomyelitis

### 10 Genitalia and rectum

Ulceration or discharge  
Testicular swelling or nodules  
Inguinal lymphadenopathy  
Prostatic tenderness  
Rectal fluctuance

▲ Testicular swelling in adult mumps

Fever		
<p><b>Documentation of fever</b></p> <ul style="list-style-type: none"> <li>• ‘Feeling hot’ or sweaty does not necessarily signify fever – diagnosed only when a body temperature of over 38.0°C is recorded</li> <li>• Axillary and aural measurement is less accurate than oral or rectal</li> <li>• Outpatients may be trained to keep a temperature chart</li> </ul>	<p><b>Night sweats</b></p> <ul style="list-style-type: none"> <li>• Associated with particular infections (e.g. TB, infective endocarditis); sweating from any cause is worse at night</li> </ul>	<p><b>Accompanying features</b></p> <ul style="list-style-type: none"> <li>• Severe headache and photophobia, although characteristic of meningitis, may accompany other infections, including parameningeal infections such as sinusitis or mastoiditis</li> <li>• Delirium during fever is more common in young children and older people</li> <li>• Myalgia may occur with viral infections, such as influenza, and with sepsis including meningococcal sepsis</li> <li>• Shock may accompany severe infections and sepsis</li> </ul>
<p><b>Rigors</b></p> <ul style="list-style-type: none"> <li>• Shivering (followed by excessive sweating) occurs with a rapid rise in body temperature from any cause</li> </ul>	<p><b>Excessive sweating</b></p> <ul style="list-style-type: none"> <li>• Alcohol, anxiety, thyrotoxicosis, diabetes mellitus, acromegaly, lymphoma and excessive environmental heat all cause sweating without temperature elevation</li> </ul>	
	<p><b>Recurrent fever</b></p> <ul style="list-style-type: none"> <li>• There are various causes, e.g. <i>Borrelia recurrentis</i>, bacterial abscess</li> </ul>	

History-taking in suspected infectious disease*		
<p><b>Presenting complaint</b></p> <ul style="list-style-type: none"> <li>• Diverse manifestations of infectious disease make accurate assessment of features and duration critical; e.g. fever and cough lasting 2 days imply an acute respiratory tract infection but raise suspicion of TB if they last 2 months</li> </ul>	<p><b>Allergy history</b></p> <ul style="list-style-type: none"> <li>• Esp. to antimicrobials, noting allergic manifestation (e.g. rash versus anaphylaxis)</li> </ul>	<p><b>Dietary history</b></p> <ul style="list-style-type: none"> <li>• Consider under-cooked meats, shellfish, unpasteurised dairy products or well water</li> <li>• Establish who else was exposed, e.g. to food-borne pathogens</li> </ul>
<p><b>Review of systems</b></p> <ul style="list-style-type: none"> <li>• Must be comprehensive</li> </ul>	<p><b>Family and contact history</b></p> <ul style="list-style-type: none"> <li>• Note infections and their duration</li> <li>• Sensitive explore exposure to key infections, e.g. TB and HIV</li> </ul>	<p><b>History of intravenous drug injection or receipt of blood products</b></p> <ul style="list-style-type: none"> <li>• Risks for blood-borne viruses, e.g. HIV-1, HBV and HCV</li> </ul>
<p><b>Past medical history</b></p> <ul style="list-style-type: none"> <li>• Define the ‘host’, comorbidities and likelihood of infection(s)</li> <li>• Include surgical and dental procedures involving prosthetic materials</li> <li>• Document previous infections and antimicrobial-resistant infections</li> </ul>	<p><b>Travel history</b></p> <ul style="list-style-type: none"> <li>• Include countries visited and where previously resident (relevant to exposure and likely vaccination history, e.g. likelihood of BCG vaccination in childhood)</li> </ul>	<p><b>Sexual history</b></p> <ul style="list-style-type: none"> <li>• Explore in a confidential manner (Ch. 15); remember HIV-1 transmission is most frequently heterosexual (Ch. 14)</li> </ul>
<p><b>Medication history</b></p> <ul style="list-style-type: none"> <li>• Include non-prescription drugs, use of antimicrobials and immunosuppressants</li> <li>• Identify medicines that interact with antimicrobials or that may cause fever</li> </ul>	<p><b>Occupation</b></p> <ul style="list-style-type: none"> <li>• e.g. Anthrax in leather tannery workers</li> </ul>	<p><b>Vaccination history and use of prophylactic medicines</b></p> <ul style="list-style-type: none"> <li>• Consider occupation- or age-related vaccines</li> <li>• In a traveller or infection-predisposed patient, establish adherence to prophylaxis</li> </ul>
<p><b>Recreational pursuits</b></p> <ul style="list-style-type: none"> <li>• e.g. Leptospirosis in canoeists and windsurfers</li> </ul>	<p><b>Animal exposures</b></p> <ul style="list-style-type: none"> <li>• Include pets, e.g. dogs/hydatid disease</li> </ul>	

\*Always consider non-infectious aetiologies in the differential diagnosis. (HBV/HCV = hepatitis B/C virus; HIV-1 = human immunodeficiency virus-1; TB = tuberculosis)

### 1 Skin lesions in infectious diseases

- Diffuse erythema, e.g. **A**
- Migrating erythema, e.g. enlarging rash of erythema migrans in Lyme disease (see Fig. 13.24)
- Purpuric or petechial rashes, e.g. **B**
- Macular or papular rashes, e.g. primary infection with HIV (see Box 14.9)
- Vesicular or blistering rash, e.g. **C**
- Erythema multiforme (see Fig. 27.54 and Box 27.33)
- Nodules or plaques, e.g. Kaposi’s sarcoma
- Erythema nodosum (**D**) and Box 27.34)

**A**

Streptococcal toxic shock syndrome.

**B**

Meningococcal sepsis.

**C**

Shingles.

**D**

Erythema nodosum.

(HIV = human immunodeficiency virus)

The principles of infection and its investigation and therapy are described in [Chapter 6](#). This chapter and the following ones on human immunodeficiency virus/acquired immunodeficiency syndrome (HIV/AIDS) and sexually transmitted infection (STI) describe the approach to patients with potential infectious disease, the individual infections and the resulting syndromes.

## Presenting problems in infectious diseases

Infectious diseases present with myriad clinical manifestations. Many of these are described in other chapters.

### Fever

'Fever' implies an elevated core body temperature of more than 38.0°C. Fever is a response to cytokines and acute phase proteins (pp. 62 and 67), and occurs both in infections and non-infectious conditions.

#### Clinical assessment

The differential diagnosis is broad so clinical features are used to guide the most appropriate investigations. The systematic approach described in this chapter should be followed. [Box 13.1](#) describes the assessment of older patients.

#### Investigations

If the clinical features do not suggest a specific infection, then initial investigations should include:

- a full blood count (FBC) with differential, including eosinophil count
- urea and electrolytes, liver function tests (LFTs), blood glucose and muscle enzymes
- inflammatory markers: erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) and/or procalcitonin (PCT) (depending on local use and availability)
- an HIV-1 antigen/antibody test
- autoantibodies, including antinuclear antibodies (ANA)
- chest X-ray and electrocardiogram (ECG)
- urinalysis and urine culture
- blood culture
- throat swab for culture or respiratory pathogen nucleic acid detection (usually by polymerase chain reaction (PCR))
- other specimens, as indicated by history and examination, e.g. wound swab; sputum culture; stool culture, microscopy for ova and parasites, and *Clostridioides difficile* toxin assay
- specific tests and their priority, indicated by geographical location: malaria films on three consecutive days or a malaria rapid diagnostic test (RDT), a test for non-structural protein 1 (NS1) in dengue (antigen detection) and blood cultures for *Salmonella* Typhi, as well as abdominal ultrasound, would be standard initial tests in many areas where these infections are prevalent.

### 13.1 Fever in old age

- **Temperature measurement:** fever may be missed because oral temperatures are unreliable. Rectal measurement may be needed but core temperature is increasingly measured using eardrum reflectance.
- **Delirium:** common with fever, especially in those with underlying cerebrovascular disease or dementia.
- **Prominent causes of pyrexia of unknown origin:** include tuberculosis and intra-abdominal abscesses, complicated urinary tract infection and infective endocarditis. Non-infective causes include polymyalgia rheumatica/temporal arteritis and tumours. A smaller fraction of cases remain undiagnosed than in young people.
- **Diagnostic pitfalls:** conditions such as stroke or thromboembolic disease can cause fever but every effort must be made to exclude concomitant infection.
- **Common infectious diseases in the very frail** (e.g. nursing home residents): pneumonia, urinary tract infection, soft tissue infection and gastroenteritis.

Subsequent investigations in patients with HIV-related, nosocomial or travel-related pyrexia, immunocompromised patients and patients with clinical features suggesting infection in the respiratory, gastrointestinal or neurological systems are described elsewhere.

### Management

Fever and its associated systemic symptoms can be treated with paracetamol, and tepid sponging to cool the skin. Replacement of salt and water is important in patients with drenching sweats. Further management is focused on the underlying cause.

### Fever with localising symptoms or signs

In most patients, the site of infection is apparent after clinical evaluation, and the likelihood of infection is reinforced by investigation results (e.g. neutrophilia with raised CRP in bacterial infections). Not all apparently localising symptoms are reliable, however; headache, breathlessness and diarrhoea can occur in systemic infection, such as sepsis or malaria, without localised infection in the central nervous system (CNS), respiratory tract or gastrointestinal tract. Abdominal pain may be a feature of basal pneumonia. Careful interpretation of the clinical features is vital (e.g. severe headache associated with photophobia, rash and neck stiffness suggests meningitis, whereas moderate headache with cough and rhinorrhoea is consistent with a viral upper respiratory tract infection).

Common infections that present with fever are shown in [Figure 13.1](#). Further investigation and management are specific to the cause, but may include empirical antimicrobial therapy ([Fig. 6.15](#)) pending confirmation of the microbiological diagnosis.

### Pyrexia of unknown origin

Pyrexia of unknown origin (PUO) was classically defined as a temperature above 38.0°C on multiple occasions for more than 3 weeks, without diagnosis, despite initial investigation in hospital for 1 week. The definition has been relaxed to allow for investigation over 3 days of inpatient care, three outpatient visits or 1 week of intensive ambulatory investigation. Subsets of PUO are described as HIV-1 related, immune-deficient or nosocomial.

#### Clinical assessment

Major causes of PUO are outlined in [Box 13.2](#). Periodic fever syndromes are rare causes that should be considered in those with a family history. Children and younger adults are more likely to have infectious causes. Older adults are more likely to have certain infectious and non-infectious causes (see [Box 13.1](#)). Detailed history and examination should be repeated at regular intervals to detect emerging features (e.g. rashes, signs of infective endocarditis or features of vasculitis). In men, the prostate should be considered as a potential source of infection.

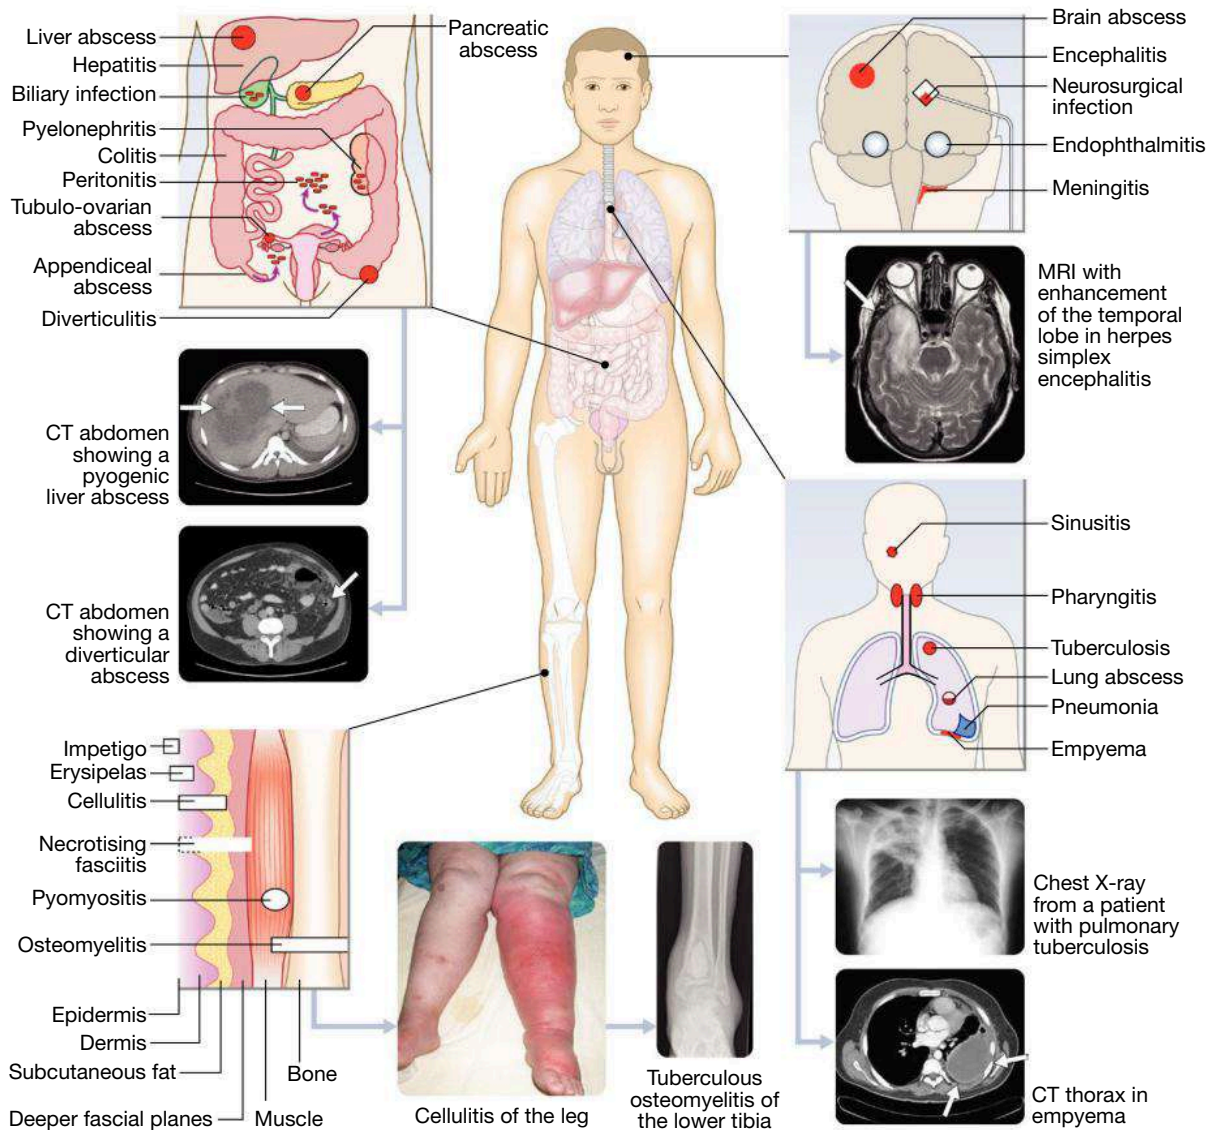

Clinicians should be alert to the possibility of factitious fever, in which high temperature recordings are engineered by the patient ([Box 13.3](#)).

#### Investigations

If initial investigations are negative, further microbiological and non-microbiological investigations should be considered ([Boxes 13.4](#) and [13.5](#)). As with initial investigation of fever described above, the prioritisation of tests will be influenced by the geographical location of potential exposure to pathogens (see [Box 13.4](#)). These will usually include:

- induced sputum or other specimens for mycobacterial stains and culture
- serological tests, including an HIV test and ferritin estimation
- imaging of the abdomen by ultrasonography or computerised tomography (CT)
- echocardiography.

Lesions identified on imaging should usually be biopsied in order to seek evidence of relevant pathogens by culture, histopathology or

**Fig. 13.1 Common infectious syndromes presenting with fever and localised features.** Major causes are grouped by approximate anatomical location and include central nervous system infection; respiratory tract infections; abdominal, pelvic or urinary tract infections; and skin and soft tissue infections (SSTIs) or osteomyelitis. For each site of infection, particular syndromes and their common causes are described elsewhere in the book. The causative organisms vary, depending on host factors, which include whether the patient has lived in or visited a tropical country or particular geographical location, has acquired the infection in a health-care environment or is immunocompromised. *Insets (cellulitis of the leg) Courtesy of Dr Ravi Gowda, Royal Hallamshire Hospital, Sheffield; (pulmonary tuberculosis) Courtesy of Dr Ann Chapman, Royal Hallamshire Hospital, Sheffield; (empyema, pyogenic liver abscess, diverticular abscess, tuberculous osteomyelitis) Courtesy of Dr Robert Peck, Royal Hallamshire Hospital, Sheffield.*

nucleic acid detection. Particularly in patients who have received prior antimicrobials, 16S rRNA analysis (Box 6.2) may aid diagnosis if a microorganism is not cultured. The chance of a successful diagnosis is greatest if procedures for obtaining and transporting the correct samples in the appropriate media are carefully planned between the clinical team, the radiologist or surgeon performing the procedure, and the local microbiologist and histopathologist. Fluorodeoxyglucose (FDG)-positron emission tomography (PET) scans may aid diagnosis of vasculitis or help selection of biopsy sites. Liver biopsy may be justified – for example, to identify idiopathic granulomatous hepatitis – if there are biochemical or radiological abnormalities. Bone marrow biopsies have a diagnostic yield of up to 15%, most often revealing haematological malignancy, myelodysplasia or tuberculosis, and also identifying brucellosis, typhoid fever or visceral leishmaniasis. Bone marrow should be sent for culture, as well as microscopy. Laparoscopy is occasionally undertaken with biopsy of abnormal tissues. Splenic aspiration in specialist centres is the diagnostic test of choice for suspected visceral leishmaniasis. Diagnostic tests for giant cell arteritis should be considered in patients over the age of 50 years, even in the absence of physical signs or a raised ESR.

‘Blind’ biopsy of other structures in the absence of localising signs or laboratory or radiology results is unhelpful.

### Prognosis

No cause is found in up to one-half of PUO cases, but as long as there is no significant weight loss or signs of another disease, the long-term mortality is low.

### Fever in the injection drug-user

Intravenous injection of recreational drugs is a global problem. Infective organisms are introduced by non-sterile (often shared) injection equipment (see Fig. 13.2). Approximately 50% of people who inject drugs (PWID) report a recent bacterial infection, with *Streptococcus pyogenes* (group A  $\beta$ -haemolytic streptococci) and *Staphylococcus aureus* infections increasing in particular. Risk factors for these infections include increasing age, homelessness and injection in prison. The risks increase with prolonged drug use and injection into large veins of the groin and neck necessitated by progressive thrombosis of superficial peripheral veins. The most common causes of fever are soft tissue or respiratory infections.

<span style="font-size: 1.2em; font-weight: bold; margin-right: 5px;">i</span> <b>13.2 Aetiology of pyrexia of unknown origin (PUO)</b>	
<p><b>Infections (~30%)</b></p> <p><b>Specific locations</b></p> <ul style="list-style-type: none"> <li>• Abscesses: hepatobiliary, diverticular, urinary tract (including prostate), pulmonary, CNS</li> <li>• Infections of oral cavity (including dental), head and neck (including sinuses)</li> <li>• Bone and joint infections</li> <li>• Infective endocarditis</li> </ul> <p><b>Specific organisms</b></p> <ul style="list-style-type: none"> <li>• TB (particularly extrapulmonary)*</li> <li>• HIV-1 infection</li> <li>• Other viral infections: cytomegalovirus (CMV), Epstein–Barr virus (EBV)</li> <li>• Fungal infections (e.g. <i>Aspergillus</i> spp., <i>Candida</i> spp. or dimorphic fungi)</li> <li>• Infections with fastidious organisms (e.g. <i>Bartonella</i> spp., <i>Tropheryma whipplei</i>)</li> </ul> <p><b>Specific patient groups</b></p> <ul style="list-style-type: none"> <li>• Recently spent time in a region with geographically restricted infection:               <ul style="list-style-type: none"> <li>• Malaria*, dengue, rickettsial infections, <i>Brucella</i> spp., amoebic liver abscess, enteric fevers (Africa, Asia, Oceania, Central and South America), <i>Leishmania</i> spp. (southern Europe, India, Africa and Latin America), <i>Burkholderia pseudomallei</i> (South-east Asia), Middle East respiratory syndrome coronavirus (MERS-CoV; Arabian Peninsula)</li> </ul> </li> <li>• Residence in or travel to a region with endemic infection:               <ul style="list-style-type: none"> <li>• TB* (Africa, Asia, Central and South America), extensively drug-resistant TB (XDR-TB; South Africa), <i>Brucella</i> spp. (Africa, Asia, Central and South America), HIV-1 (Africa, Asia), <i>Trypanosoma cruzi</i> (Central and South America)</li> </ul> </li> <li>• Nosocomial infections:               <ul style="list-style-type: none"> <li>• Pneumonia*, infections related to prosthetic materials and surgical procedures, urinary tract infections, central venous catheter infections</li> </ul> </li> <li>• HIV-positive individuals:               <ul style="list-style-type: none"> <li>• Acute retroviral syndrome</li> <li>• AIDS-defining infections (disseminated <i>Mycobacterium avium</i> complex (DMAC), <i>Pneumocystis jirovecii</i> pneumonia, CMV and others)</li> </ul> </li> </ul>	<p><b>Connective tissue disorders (~15%)</b></p> <p><b>Older adults</b></p> <ul style="list-style-type: none"> <li>• Temporal arteritis/polymyalgia rheumatica*</li> </ul> <p><b>Younger adults</b></p> <ul style="list-style-type: none"> <li>• Still's disease (juvenile rheumatoid arthritis)*</li> <li>• Systemic lupus erythematosus (SLE)</li> <li>• Vasculitic disorders, including polyarteritis nodosa, rheumatoid disease with vasculitis and granulomatosis with polyangiitis (formerly known as Wegener's granulomatosis)</li> <li>• Polymyositis</li> <li>• Behçet's disease</li> <li>• Rheumatic fever (in regions where still endemic, e.g. Asia, Oceania and parts of Africa)</li> </ul> <p><b>Miscellaneous (~20%)</b></p> <p><b>Cardiovascular</b></p> <ul style="list-style-type: none"> <li>• Atrial myxoma, aortitis, aortic dissection</li> </ul> <p><b>Respiratory</b></p> <ul style="list-style-type: none"> <li>• Sarcoidosis, pulmonary embolism and other thromboembolic disease, extrinsic allergic alveolitis</li> </ul> <p><b>Gastrointestinal</b></p> <ul style="list-style-type: none"> <li>• Inflammatory bowel disease, granulomatous hepatitis, alcoholic liver disease, pancreatitis</li> </ul> <p><b>Endocrine/metabolic</b></p> <ul style="list-style-type: none"> <li>• Thyrotoxicosis, thyroiditis, hypothalamic lesions, phaeochromocytoma, adrenal insufficiency, hypertriglyceridaemia</li> </ul> <p><b>Haematological</b></p> <ul style="list-style-type: none"> <li>• Haemolytic anaemia, paroxysmal nocturnal haemoglobinuria, thrombotic thrombocytopenic purpura, myeloproliferative disorders, Castleman's disease, graft-versus-host disease (after allogeneic haematopoietic stem cell transplantation)</li> </ul> <p><b>Inherited</b></p> <ul style="list-style-type: none"> <li>• Familial Mediterranean fever and periodic fever syndromes</li> </ul> <p><b>Drug reactions*</b></p> <ul style="list-style-type: none"> <li>• e.g. Antibiotic fever, drug hypersensitivity reactions etc.</li> </ul> <p><b>Factitious fever</b></p> <p><b>Idiopathic (~15%)</b></p>

<ul style="list-style-type: none"> <li>• A patient who looks well</li> <li>• Bizarre temperature chart with absence of diurnal variation and/or temperature-related changes in pulse rate</li> <li>• Temperature &gt; 41°C</li> <li>• Absence of sweating during defervescence</li> <li>• Normal erythrocyte sedimentation rate and C-reactive protein despite high fever</li> <li>• Evidence of self-injection or self-harm</li> <li>• Normal temperature during supervised (observed) measurement</li> <li>• Infection with multiple commensal organisms (e.g. enteric or mouth flora)</li> </ul>

### Clinical assessment

The history should address the following risk factors:

- *Site of injection.* Femoral vein injection is associated with vascular complications such as deep venous thrombosis (DVT; 50% of which are septic) and accidental arterial injection with false aneurysm formation or a compartment syndrome due to swelling within the fascial sheath. Local complications include ilio-psoas abscess, and septic arthritis of the hip joint or sacroiliac joint. Injection of the jugular vein can be associated with cerebrovascular complications.

Subcutaneous and intramuscular injection has been related to infection by clostridial species, the spores of which contaminate heroin. *Clostridium novyi* causes a local lesion with significant toxin production, leading to shock and multi-organ failure. Tetanus, wound botulism, anthrax and gas gangrene also occur.

- *Technical details of injection.* Sharing of needles and other injecting paraphernalia (including spoons and filters) increases the risk of blood-borne virus infection (e.g. HIV-1, hepatitis B or C virus). Some users lubricate their needles by licking them prior to injection, thus introducing mouth organisms (e.g. anaerobic streptococci, *Fusobacterium* spp. and *Prevotella* spp.). Contamination of commercially available lemon juice, used to dissolve heroin before injection, has been associated with blood-stream infection with *Candida* spp. Excessive use of citric acid to dissolve heroin is associated with DVT and skin and soft tissue infection.
- *Substances injected.* Injection of cocaine is associated with a variety of vascular complications. Psychoactive drugs increase risk taking and bacterial infections. Certain formulations of heroin have been linked with particular infections, e.g. wound botulism with black tar heroin. Drugs are often mixed with other substances, e.g. talc.

### 13.4 Microbiological investigation of pyrexia of unknown origin<sup>1</sup>

#### Location-independent investigations

##### Microscopy

- Blood for atypical lymphocytes (EBV, CMV, HIV-1, hepatitis viruses or *Toxoplasma gondii*)
- Respiratory samples for mycobacteria and fungi
- Stool for ova, cysts and parasites
- Biopsy for light microscopy (bacteria, mycobacteria, fungi) and/or electron microscopy (viruses, protozoa (e.g. microsporidia) and other fastidious organisms (e.g. *Tropheryma whippelii*))
- Urine for white or red blood cells and mycobacteria (early morning urine ×3)

##### Culture

- Aspirates and biopsies (e.g. joint, deep abscess, débrided tissues)
- Blood, including prolonged culture and special media conditions
- Sputum for mycobacteria
- CSF
- Gastric aspirate for mycobacteria
- Stool
- Swabs
- Urine ± prostatic massage in older men

##### Antigen detection

- Blood, e.g. HIV p24 antigen (usually combined with an antibody test), cryptococcal antigen, *Aspergillus* galactomannan ELISA and (1,3)-β-D-glucan (for fungi other than mucoraceous moulds and *Cryptococcus*)
- CSF for cryptococcal antigen
- Bronchoalveolar lavage fluid for *Aspergillus* galactomannan
- Nasopharyngeal aspirate/throat swab for respiratory viruses, e.g. IAV or RSV
- Urine, e.g. for *Legionella* antigen

##### Nucleic acid detection

- Blood for *Bartonella* spp. and viruses
- CSF for viruses and key bacteria (meningococcus, pneumococcus, *Listeria monocytogenes*)

- Nasopharyngeal aspirate/throat swab for respiratory viruses
- Sputum for *Mycobacterium tuberculosis* (MTB) and rifampicin (RIF) resistance with geneXpert MTB/RIF cartridge-based nucleic acid amplification test (NAAT)
- Bronchoalveolar lavage fluid, e.g. for respiratory viruses
- Tissue specimens, e.g. for *T. whippelii*
- Urine, e.g. for *Chlamydia trachomatis*, *Neisseria gonorrhoeae*
- Stool, e.g. for norovirus, rotavirus

##### Immunological tests

- Serology (antibody detection) for viruses, including HIV-1, and some bacteria
- Interferon-gamma release assay for diagnosis of exposure to tuberculosis (but note this will not distinguish latent from active disease and can only be used to trigger further investigations of active disease)

##### Geographically restricted tests<sup>2</sup>

##### Microscopy

- Blood for trypanosomiasis, malaria and *Borrelia* spp.
- Stool for geographically restricted ova, cysts and parasites
- Biopsy for light microscopy (dimorphic fungi, *Leishmania* spp. and other parasites)
- Urine for red blood cells and schistosome ova

##### Antigen detection

- Blood, e.g. dengue virus NS1 antigen, *Histoplasma* antigen (restricted availability) and malaria antigen (e.g. HRP-2 for *Plasmodium falciparum* or parasite-specific LDH for *P. falciparum* and *P. vivax*)

##### Nucleic acid detection

- Blood for causes of viral haemorrhagic fever
- CSF for geographically restricted viruses, e.g. Japanese encephalitis virus
- Nasopharyngeal aspirate/throat swab or bronchoalveolar lavage fluid for geographically restricted respiratory viruses, e.g. MERS-CoV

##### Immunological tests

- Serology (antibody detection) for viruses, dimorphic fungi and protozoa

<sup>1</sup>This list does not apply to every patient with a pyrexia of unknown origin. Appropriate tests should be selected in a stepwise manner, according to specific predisposing factors, epidemiological exposures and local availability, and should be discussed with a microbiologist. <sup>2</sup>Addition of these tests should be guided by the location of presentation or travel history. (CMV = cytomegalovirus; CSF = cerebrospinal fluid; EBV = Epstein-Barr virus; ELISA = enzyme-linked immunosorbent assay; HIV-1 = human immunodeficiency virus-1; HRP-2 = histidine-rich protein 2; IAV = influenza A virus; LDH = lactate dehydrogenase; MERS-CoV = Middle East respiratory syndrome coronavirus; NS1 = non-structural 1; RSV = respiratory syncytial virus)

### 13.5 Additional investigations to be considered in pyrexia of unknown origin (PUO)

- Serological tests for connective tissue disorders:
  - Autoantibody screen
  - Complement levels
  - Immunoglobulins
  - Cryoglobulins
- Ferritin
- Echocardiography
- Ultrasound of abdomen
- CT/MRI of thorax, abdomen and/or brain
- Imaging of the skeletal system:
  - Plain X-rays
  - CT/MRI spine
  - Isotope bone scan

- Labelled white cell scan
- Fluorodeoxyglucose-positron emission tomography (FDG-PET)/single-photon emission computed tomography (SPECT)
- Biopsy:
  - Bronchoscopy and lavage ± transbronchial biopsy
  - Lymph node aspirate or biopsy
  - Biopsy of radiological lesion
  - Biopsy of liver
  - Bone marrow aspirate and biopsy
  - Lumbar puncture
  - Laparoscopy and biopsy
  - Temporal artery biopsy

- *Blood-borne virus status*. Results of previous HIV-1 and hepatitis virus tests or vaccinations for hepatitis viruses should be recorded.
- *Surreptitious use of antimicrobials*. Addicts may use antimicrobials to self-treat infections, masking initial blood culture results.

Key findings on clinical examination are shown in [Figure 13.2](#). It can be difficult to distinguish the effects of infection from the effects of drugs or drug withdrawal (excitement, tachycardia, sweating, marked myalgia, delirium). Stupor and delirium may result from drug administration but may also indicate meningitis or encephalitis. Non-infected venous thromboembolism is also common in this group.

#### Investigations

The initial investigations are as for any fever (see above), including a chest X-ray and blood cultures. Since blood sampling may be difficult, contamination is often a problem. Echocardiography (transthoracic or transoesophageal) to detect infective endocarditis should be performed in all injection drug-users with bacteraemia due to *Staph. aureus* or other organisms associated with endocarditis ([Fig. 13.3A](#)); thromboembolic phenomena; or a new or previously undocumented murmur. Endovascular infection should also be suspected if lung abscesses or pneumatoceles are detected radiologically. Infected thrombus at injection sites, such as the groin, is common and may lead to abscess

**6 Cardiovascular system**

Systolic 'V' waves in JVP of tricuspid regurgitation (Ch. 16)  
Regurgitant murmurs in endocarditis

**5 Nervous system**

Signs of drug intoxication  
Encephalopathy

formation. Additional imaging should be focused on sites of injection or of localising symptoms (Fig. 13.3B). Any pathological fluid collections should be sampled.

Urinary toxicology tests may suggest a non-infectious cause of the presenting complaint. While being investigated, all injection drug-users should be tested for infection with hepatitis B and C virus and HIV-1.

Injection drug-users may have more than one infection. Skin and soft tissue infections are most often due to *Staph. aureus* or streptococci, and sometimes to *Clostridium* spp. or anaerobes. Pulmonary infections are most often due to the common pathogens causing community-acquired pneumonia, tuberculosis or septic emboli (Fig. 13.3C). Endocarditis with septic emboli commonly involves *Staph. aureus* and viridans streptococci, but *Pseudomonas aeruginosa* and *Candida* spp. are also encountered.

**Management**

Empirical therapy of fever in the injection drug-user includes an anti-staphylococcal penicillin (e.g. flucloxacillin) or, where methicillin-resistant *Staph. aureus* (MRSA) is prevalent, a glycopeptide (e.g. vancomycin) or lipopeptide (e.g. daptomycin). Once microbiological results are available,

therapy can be narrowed to focus on the microorganism identified. In injection drug-users, methicillin-sensitive *Staph. aureus* is customarily treated with high-dose intravenous (IV) flucloxacillin, with a 2-week duration for uncomplicated right-sided endocarditis. Right-sided endocarditis caused by MRSA is usually treated with 4 weeks of vancomycin. Specialist advice should be sought.

For localised infections of the skin and soft tissues, oral therapy with agents active against staphylococci, streptococci and anaerobes is appropriate (e.g. flucloxacillin or clindamycin). Non-adherence to prescribed antimicrobial regimens leads to a high rate of complications.

**Fever in the immunocompromised host**

Immunocompromised hosts include those with congenital immunodeficiency, HIV infection and iatrogenic immunosuppression induced by chemotherapy, or immunosuppressant medicines, including high-dose glucocorticoids. Metabolic abnormalities, such as under-nutrition or hyperglycaemia, may also contribute. Multiple elements of the immune system are potentially compromised. A patient may have impaired

**Fig. 13.3** Causes of fever in injection drug-users. **[A]** Endocarditis: large vegetation on the tricuspid valve (arrow). **[B]** Septic arthritis of the left sternoclavicular joint (arrow A) (note the erosion of the bony surfaces at the sternoclavicular joint) with overlying soft tissue collection (arrow B). **[C]** Tricuspid valve endocarditis caused by *Staph. aureus*. neutrophil function from chemotherapy, impaired T-cell and/or B-cell responses due to underlying malignancy, T-cell and phagocytosis defects due to glucocorticoids, mucositis from chemotherapy and an impaired skin barrier due to insertion of a central venous catheter.

Fever may result from infectious or non-infectious causes, including drugs, vasculitis, neoplasm, lymphoproliferative disease, graft-versus-host disease (in recipients of haematopoietic stem cell transplants (HSCT)), organising pneumonitis or Sweet syndrome (reddish nodules or plaques with fever and leucocytosis, in association with haematological malignancy).

Although many infections in immunocompromised patients are caused by common organisms they may also be infected with organisms that cause infection in the non-immunocompromised host rarely, or not at all (opportunistic pathogens/opportunistic infections).

### Clinical assessment

The following should be addressed in the history:

- identification of the immunosuppressant factors and nature of the immune defect
- any past infections and their treatment, including antimicrobial-resistant or recurrent infections

- epidemiological risk factors increasing exposure to infections, including opportunistic infections that would not cause disease in an immunocompetent host
- prophylactic medicines and vaccinations administered.

Examination should include inspection of the skin, any central venous catheters, the mouth, sinuses, ears and perianal area (digital rectal examination should be avoided). Disseminated infections can manifest as cutaneous lesions. The areas around fingernails and toenails should also be inspected closely.

### Investigations

Initial screening tests are as described above. Immunocompromised hosts often have decreased inflammatory responses leading to attenuation of physical signs, such as neck stiffness with meningitis, radiological features and laboratory findings, such as leucocytosis. Chest CT scan should be considered in addition to chest X-ray when respiratory symptoms occur. Abdominal imaging may also be warranted, particularly if there is right lower quadrant pain, which may indicate typhlitis (inflammation of the caecum) in neutropenic patients. Blood cultures from a central venous catheter, urine cultures and stool cultures if diarrhoea is present are also recommended.

Nasopharyngeal aspirates are sometimes diagnostic, as immunocompromised hosts may shed respiratory viruses for prolonged periods. Skin lesions should be biopsied if nodules are present, and investigation should include fungal stains. Useful molecular techniques include PCR for cytomegalovirus (CMV) and *Aspergillus* spp. DNA. Antigen assays that may be used include blood tests for cryptococcal antigen (CrAg), *Aspergillus* galactomannan, (1,3)- $\beta$ -D-glucan (for *Pneumocystis jirovecii* and fungi other than *Cryptococcus* spp. and mucoraceous moulds) and a urine test for *Legionella pneumophila* type 1. Antibody detection is rarely useful in immunocompromised patients. Patients with respiratory signs or symptoms should be considered for bronchoalveolar lavage to detect *Pneumocystis jirovecii*, other fungi, bacteria and viruses.

### Neutropenic fever

Patients with neutropenia are highly susceptible to bacterial and fungal infection, the risk of which increases progressively as the neutrophil count drops below  $1.0 \times 10^9/L$ . Gram-positive organisms are the most common pathogens, particularly in association with in-dwelling catheters. There is no universal definition of neutropenic fever, but most authorities define neutropenia as a neutrophil count of  $<0.5 \times 10^9/L$  (p. 935) and fever as a single measurement  $>38.5^\circ C$  or sustained temperature  $>38^\circ C$ .

Empirical broad-spectrum antimicrobial therapy is commenced when cultures have been obtained. The most common regimens for neutropenic fever are broad-spectrum penicillins, e.g. piperacillin–tazobactam. The routine addition of aminoglycosides to these agents is not supported by trial data. If fever has not resolved after 3–5 days, empirical antifungal therapy (e.g. caspofungin) is added (p. 122). An alternative antifungal strategy is to use azole prophylaxis in high-risk patients and markers of early fungal infection, such as galactomannan, (1,3)- $\beta$ -D-glucan and/or fungal PCR, to guide initiation of antifungal treatment (a ‘pre-emptive approach’).

### Post-transplantation fever

Fever in transplant recipients may be due to infection, episodes of graft rejection in solid organ transplant recipients, or graft-versus-host disease following haematopoietic stem cell transplantation.

Infections in solid organ transplant recipients are grouped according to the time of onset (Box 13.6). Those in the first month are mostly related to the underlying condition or surgical complications. Those occurring 1–6 months after transplantation are characteristic of impaired T-cell function. Risk factors for CMV infection have been identified; patients commonly receive either prophylaxis or intensive monitoring involving regular testing for CMV DNA by PCR and early initiation of anti-CMV therapy using

13.6 Infections in transplant recipients	
Time post-transplantation	Infections
<b>Solid organ transplant recipients</b>	
0–1 month	Bacterial or fungal infections related to the underlying condition or surgical complications
1–6 months	CMV, other opportunistic infections (e.g. <i>Pneumocystis jirovecii</i> pneumonia)
>6 months	Bacterial pneumonia, other bacterial community-acquired infections, shingles, cryptococcal infection, PTLD
<b>Myeloablative haematopoietic stem cell transplant recipients</b>	
Pre-engraftment (typically 0–4 weeks)	Bacterial and fungal infections, respiratory viruses or HSV reactivation
Post-engraftment:	
Early (<100 days)	CMV, <i>Pneumocystis jirovecii</i> pneumonia, moulds or other opportunistic infections
Late (>100 days)	Community-acquired bacterial infections, shingles, CMV, PTLD
(CMV = cytomegalovirus; HSV = herpes simplex virus; PTLD = post-transplant lymphoproliferative disorder)	

intravenous ganciclovir or oral valganciclovir if tests become positive. Greater use of prophylactic regimens, despite reducing infections overall, is extending the period of risk so that some opportunistic infections, e.g. CMV, may be seen after this initial 6-month period.

Following HSCT, infections in the first 4 weeks are more common in patients receiving a myeloablative-conditioning regimen (see Box 13.6). Later infections are more common if an allogeneic, as opposed to autologous, procedure is performed.

Post-transplant lymphoproliferative disorder (PTLD) is an Epstein–Barr virus (EBV)-associated lymphoma that can complicate transplantation, particularly when primary EBV infection occurs after transplantation.

### Positive blood culture

Blood-stream infection (BSI) is a frequent presentation of infection. This can be community-acquired or hospital-acquired ('nosocomial'). Common causes are shown in Fig. 13.4. In immunocompromised hosts, a wider range of microorganisms may be isolated, e.g. fungi.

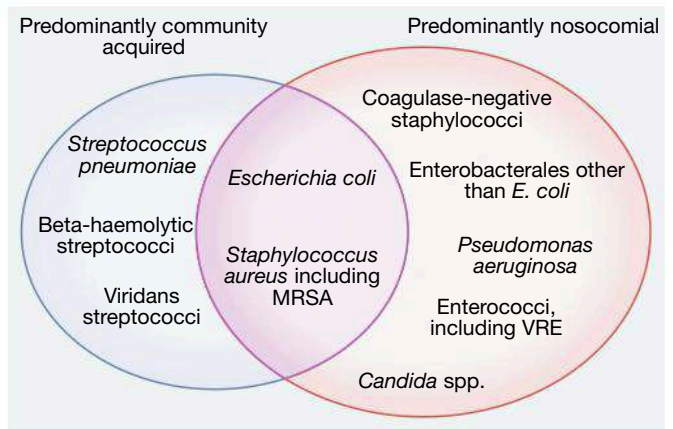

Primary BSI refers to cases in which an extravascular source of infection (e.g. pneumonia or urinary tract infection) is not identified, and is commonly caused by *Staph. aureus*. In community-acquired *Staph. aureus* bacteraemia, 20%–30% of cases are associated with infective endocarditis and up to 10% are due to osteomyelitis. Peripheral and central venous catheters are an important source of nosocomial BSI.

BSI has an associated mortality of 15%–40%, depending on the setting, host and microbial factors.

### Clinical assessment

The history should determine the setting in which BSI has occurred. Host factors predisposing to infection include skin disease, diabetes mellitus, injection drug use, the presence of a central venous, urinary or haemodialysis catheter, and surgical procedures, especially those involving the implantation of prosthetic materials (in particular, endovascular prostheses).

Physical examination should focus on signs of infective endocarditis (p. 462), evidence of bone (especially spinal) or joint infection (tenderness or restriction of movement), and abdominal or flank tenderness. Central venous catheters should be examined for erythema or purulence

**Fig. 13.4 Common causes of blood-stream infection.** Causes of community- and hospital-acquired blood-stream infection are subject to significant regional and geographic location. (MRSA = methicillin-resistant *Staphylococcus aureus*; VRE = vancomycin-resistant *Enterococcus* spp.)

at the exit site. Particularly in cases with *Candida* spp. infection or suspected infective endocarditis, fundoscopy after pupil dilatation should be performed.

### Investigations

Positive blood cultures may be caused by contaminants. When isolated from only one bottle, or from all bottles from one venesection, coagulase-negative staphylococci often represent contamination. Repeated isolation of coagulase-negative staphylococci, however, should raise suspicion of infective endocarditis or, in a patient with any form of prosthetic material, prosthesis infection. Viridans streptococci occasionally cause transient non-significant bacteraemia or blood culture contamination but, in view of their association with infective endocarditis, significant infection must always be excluded. *Bacillus* spp. ('aerobic spore bearers') and *Clostridium* spp. often represent incidental transient bacteraemia or contamination, but certain species (e.g. *C. septicum*) are more likely to be genuine pathogens.

Further investigations are influenced by the causative organism and setting. Initial screening tests are similar to those for fever and should include chest X-ray, urine culture and, in many cases, ultrasound or other imaging of the abdomen. Imaging should also include any areas of bone or joint pain and any prosthetic material, e.g. a prosthetic joint or an aortic graft.

Echocardiography should be considered for those patients with BSI who have valvular heart disease or clinical features of endocarditis, those whose cultures reveal an organism that is a common cause of endocarditis (e.g. *Staph. aureus*, viridans streptococci or enterococci), those in whom multiple blood cultures are positive for the same organism, and those with a rapid positive result on culture. The sensitivities of transthoracic echocardiography (TTE) and transoesophageal echocardiography (TOE) for the detection of vegetations are 50%–90% and over 95%, respectively. Therefore, if TTE is negative, TOE should be considered.

Certain rare causes of BSI have specific associations that warrant further investigation. Endocarditis caused by *Streptococcus gallolyticus* subsp. *gallolyticus* (formerly *Strep. bovis* biotype I) and BSI with *C. septicum* are both associated with colonic carcinoma and should lead to appropriate investigation.

### Management

BSI is treated with antimicrobial therapy and, where possible, source control (surgical drainage, joint washout etc.). Two weeks of therapy may be sufficient for *Staph. aureus* BSI from central and peripheral venous catheter infections when the source is identified and removed, for uncomplicated skin and soft tissue infections, and for uncomplicated right-sided infective endocarditis. Other *Staph. aureus* BSIs are usually treated for 4–6 weeks.

## Central venous catheter infections

Infections of central venous catheters typically involve the catheter lumen and are associated with fever, positive blood cultures and, in some cases, signs of purulence or exudate at the site of insertion. Infection is more common in temporary catheters inserted into the groin or jugular vein than in those in the subclavian vein. Tunnelled catheters, e.g. Hickman catheters, may also develop tunnel site infections.

Staphylococci account for 70%–90% of catheter infections, with coagulase-negative staphylococci more common than *Staph. aureus*. Other causes include enterococci and Gram-negative bacilli. Unusual Gram-negative organisms, such as *Citrobacter freundii* and *Pseudomonas fluorescens*, raise the possibility of non-sterile infusion equipment or infusate. *Candida* spp. are a common cause of line infections, particularly in association with total parenteral nutrition. Non-tuberculous mycobacteria may cause tunnel infections.

### Investigations and management

In bacteraemic patients with fever and no other obvious source of infection, a catheter infection is likely. Local evidence of erythema, purulence or thrombophlebitis supports the diagnosis but microbiological confirmation is essential. If the line is removed a semi-quantitative culture of the tip may confirm the presence of 15 or more colony-forming units, but this technique is retrospective and does not detect luminal infection. If the catheter remains in place, paired blood cultures (with approximately equal volumes) should be taken through the catheter and from a peripheral vein. A differential time to positive culture of 2 hours or more, with the catheter sample coming up positive first, suggests a luminal catheter infection.

For coagulase-negative staphylococcal line infections, the options are to remove the line and provide 5–7 days' therapy or, particularly in the case of tunnelled catheters, to treat empirically with a glycopeptide antibiotic, e.g. vancomycin, with or without the use of antibiotic-containing lock therapy to the catheter for approximately 14 days. For *Staph. aureus* infection, the chance of curing an infection with the catheter in situ is low and the risks from infection are high. Therefore, unless the risks of catheter removal outweigh the benefits, treatment involves catheter removal, followed by 14 days of antimicrobial therapy; the same applies to infections with *Pseudomonas aeruginosa*, *Candida* spp., atypical mycobacteria or *Bacillus* spp. Infections complicated by endocarditis, thrombophlebitis, metastatic infection or tunnel infection also require catheter removal.

Infection prevention is a key component of the management of vascular catheters. Measures include strict attention to hand hygiene, optimal siting, full aseptic technique on insertion and subsequent interventions, skin antisepsis with chlorhexidine and isopropyl alcohol, daily assessment of catheter sites (e.g. with visual infusion phlebitis (VIP) score; see Box 13.39), and daily consideration of the continuing requirement for catheterisation. The use of catheters impregnated with antimicrobials, such as chlorhexidine or silver, is advocated in some settings.

## Sepsis

Sepsis is discussed on page 198 and there are many causes (Box 13.7). The results of blood cultures and pre-existing host factors guide initial investigations. Patients who are immunocompromised may have a broader range of causal pathogens that may be harder to culture, including mycobacteria and fungi. In many regions, malaria and dengue must also be excluded.

## Severe skin and soft tissue infections

Skin and soft tissue infections (SSTIs) are an important cause of sepsis. Cases can be classified as in Box 13.8, according to the clinical features and microbiological findings. In some cases, severe systemic features may be out of keeping with mild local features.

13.7 Causes of sepsis	
Infection	Setting
<b>Bacterial</b>	
<i>Staph. aureus</i> , coagulase-negative staphylococci	Bacteraemia may be associated with endocarditis, intravascular cannula infection, or skin or bone foci
<i>Streptococcus pneumoniae</i>	Invasive pneumococcal disease, usually with pneumonia or meningitis; asplenia
Other streptococci	Invasive streptococcal disease, especially necrotising fasciitis
Staphylococcal or streptococcal toxic shock syndrome	Viridans streptococci in neutropenic host with severe mucositis
Enterococci	Toxin-mediated, blood cultures negative; clues include erythrodermic rash and epidemiological setting
<i>Neisseria meningitidis</i>	Most often with abdominal focus
<i>Escherichia coli</i> , other Gram-negative bacteria	Sepsis in children or young adults with petechial rash and/or meningitis
<i>Pseudomonas aeruginosa</i> , multidrug-resistant Gram-negative bacteraemia	Urinary or biliary tract infection, or other abdominal infections
<i>Salmonella</i> Typhi or Paratyphi	Nosocomial infection
<i>Yersinia pestis</i>	In countries with a high incidence of enteric fever
<i>Burkholderia pseudomallei</i>	In plague
<i>Capnocytophaga canimorsus</i>	Endemic in areas of Thailand; more likely to involve patients with diabetes mellitus or immunocompromised
<i>Clostridioides difficile</i>	Associated with dog bites and asplenic individuals
Polymicrobial infection with Gram-negatives and anaerobes	Severe colitis, particularly in older adults
<i>Mycobacterium tuberculosis</i> , <i>M. avium</i> complex (MAC)	Bowel perforation, bowel ischaemia
<b>Fungal</b>	
<i>Candida</i> spp.	HIV-positive or immunocompromised with miliary tuberculosis or disseminated MAC
<i>Histoplasma capsulatum</i> , other dimorphic fungi	Line infection or post-operative complication, nosocomial or immunocompromised host
<b>Parasitic</b>	
<i>Falciparum</i> malaria	Immunocompromised host
<i>Babesia microti</i>	Malaria with high-level parasitaemia and multi-organ failure or as a complication of bacterial superinfection
<i>Strongyloides stercoralis</i>	Asplenic individual
hyperinfection syndrome	Gram-negative infection complicating <i>Strongyloides</i> infection in immunocompromised host

(HIV = human immunodeficiency virus)

## Necrotising fasciitis

In necrotising fasciitis, cutaneous erythema and oedema progress to bullae or areas of necrosis. Unlike in cellulitis, pain may be disproportionate to the visible cutaneous features or may spread beyond the zone of erythema. The infection spreads quickly along the fascial plane. Type 1 necrotising fasciitis is a mixed infection with Gram-negative bacteria and anaerobes, often seen post-operatively in diabetic or immunocompromised hosts. Subcutaneous gas may be present. Type 2 necrotising fasciitis is caused by group A or other streptococci. Approximately

### 13.8 Severe necrotising soft tissue infections

- Necrotising fasciitis (primarily confined to subcutaneous fascia and fat)
- Clostridial anaerobic cellulitis (confined to skin and subcutaneous tissue)
- Non-clostridial anaerobic cellulitis
- Progressive bacterial synergistic gangrene (*Staph. aureus* + micro-aerophilic streptococcus) ('Meleney's gangrene', primarily confined to skin)
- Pyomyositis (discrete abscesses within individual muscle groups)
- Clostridial myonecrosis (gas gangrene)
- Anaerobic streptococcal myonecrosis (non-clostridial infection mimicking gas gangrene)
- Group A streptococcal necrotising myositis

Fig. 13.5 Excision following necrotising fasciitis in an injection drug-user.

60% of cases are associated with streptococcal toxic shock syndrome (p. 302). Type 3 infection involves organisms such as *Aeromonas hydrophila* and *Vibrio vulnificus*, which is found in tropical to subtropical regions and is associated with marine exposure. Type 4 is caused by fungi such as mucoraceous moulds and may also vary geographically in incidence, with recent reports of increased cases in India and other regions.

Necrotising fasciitis is a medical emergency, requiring immediate surgical débridement with inspection of the involved muscle groups, in addition to antimicrobial therapy (Fig. 13.5). Empirical treatment is with broad-spectrum agents (e.g. piperacillin–tazobactam plus clindamycin; meropenem with clindamycin). Ceftazidime or ciprofloxacin with doxycycline may be used where marine exposure is a factor, and antifungals for suspected fungal necrotising fasciitis, but it is important to combine these with effective coverage against streptococcal infection. MRSA-associated necrotising fasciitis has emerged in some regions, where glycopeptides or linezolid should be added to the empirical regimen to cover MRSA until microbiological results allow focused therapy. Hyperbaric oxygen therapy may be considered for polymicrobial infection. Group A streptococcal infection is treated with benzylpenicillin plus clindamycin, and often immunoglobulin, though to date clinical trials have not provided clear evidence of the benefit of immunoglobulin.

#### Gas gangrene

Although *Clostridium* spp. may colonise or contaminate wounds, no action is required unless there is evidence of spreading infection.

Anaerobic cellulitis occurs when *C. perfringens*, or other clostridia, infect devitalised tissue, usually following a wound. Gas forms locally and extends along tissue planes but bacteraemia does not occur. Prompt surgical débridement of devitalised tissue and therapy with penicillin or clindamycin is usually effective.

Gas gangrene (clostridial myonecrosis) is defined as acute invasion of healthy living muscle undamaged by previous trauma, and is most commonly caused by *C. perfringens*. In at least 70% of cases it follows deep penetrating injury sufficient to create an anaerobic (ischaemic)

environment, allowing clostridial proliferation. Severe pain at the site of the injury progresses rapidly over 18–24 hours. Skin colour changes from pallor to bronze/purple discoloration and the skin is tense, swollen, oedematous and exquisitely tender. Gas in tissues may be obvious, with crepitus on clinical examination, or visible on X-ray, CT or ultrasound. Signs of systemic toxicity develop rapidly, with high leucocytosis, multi-organ dysfunction, raised creatine kinase and evidence of disseminated intravascular coagulation and haemolysis. Antibiotic therapy with high-dose intravenous penicillin and clindamycin is recommended, coupled with aggressive surgical débridement of the affected tissues. Alternative agents include cephalosporins and metronidazole. Hyperbaric oxygen has a putative but controversial role.

#### Other SSTIs

'Synergistic gangrene' is a polymicrobial infection with anaerobes and other bacteria (*Staph. aureus* or Gram-negatives). When this affects the genital/perineal area, it is known as 'Fournier's gangrene'. Severe gangrenous cellulitis in immunocompromised hosts may involve Gram-negative bacteria or fungi. *Entamoeba histolytica* can cause soft tissue necrosis following abdominal surgery in areas of the world where infection is common. Contact with sea water or shellfish consumption in tropical to subtropical regions worldwide, such as the Gulf of Mexico, can lead to infection with *Vibrio vulnificus*. This infection causes soft tissue necrosis and bullae, and may lead to necrotising fasciitis. Patients with chronic liver disease are particularly susceptible to this infection and can develop sepsis.

### Acute diarrhoea and vomiting

Acute diarrhoea, sometimes with vomiting, is the predominant symptom in infective gastroenteritis (Box 13.9). Acute diarrhoea may also be a symptom of other infectious and non-infectious diseases (Box 13.10). Stress, whether psychological or physical, can also produce loose stools.

Global Burden of Disease 2016 estimates suggest acute diarrhoea causes 1.7 million deaths annually, a quarter in children under 5. In high-income countries older people are most susceptible (Box 13.11). The majority of episodes are due to infections spread by the faecal–oral route and transmitted either on fomites, on contaminated hands or in food or water. Provision of clean drinking water, appropriate disposal of human and animal sewage, and the application of simple principles of food hygiene all limit gastroenteritis (water, sanitation and hygiene – WASH).

Some organisms (*Bacillus cereus*, *Staph. aureus* and *Vibrio cholerae*) elute exotoxins that cause vomiting and/or so-called 'secretory' diarrhoea (watery diarrhoea without blood or faecal leucocytes, reflecting

### 13.9 Causes of infectious gastroenteritis

#### Toxin in food: <6 hrs incubation

- *Bacillus cereus*
- *Staph. aureus*
- *Clostridium* spp. enterotoxin

#### Bacterial: 12–72 hrs incubation

- Enterotoxigenic *Escherichia coli* (ETEC)
- Shiga toxin-producing *E. coli* (EHEC)\*
- Entero-invasive *E. coli* (EIEC)\*
- *Vibrio cholerae*
- *Salmonella*
- *Shigella*\*
- *Campylobacter*\*
- *Clostridioides difficile*\*

#### Viral: short incubation

- Rotavirus
- Norovirus

#### Protozoal: long incubation

- Giardiasis
- Cryptosporidiosis
- Microsporidiosis
- Amoebic dysentery\*
- Cystoisosporiasis

\*Associated with bloody diarrhoea.

### 13.10 Differential diagnosis of acute diarrhoea and vomiting

#### Infectious causes

- Gastroenteritis
- *Clostridioides difficile* infection
- Acute diverticulitis (p. 832)
- Sepsis (p. 198)
- Pelvic inflammatory disease (p. 375)
- Meningococcaemia
- Pneumonia (especially 'atypical disease', p. 512)
- Malaria

#### Non-infectious causes

##### Gastrointestinal

- Inflammatory bowel disease (p. 835)
- Bowel malignancy (p. 826)
- Overflow from constipation (p. 833)
- Enteral tube feeding

##### Metabolic

- Diabetic ketoacidosis (p. 721)
- Thyrotoxicosis (p. 652)
- Uraemia (p. 588)
- Neuro-endocrine tumours releasing (e.g.) VIP or 5-HT

##### Drugs and toxins

- NSAIDs
- Cytotoxic agents
- Antibiotics
- Proton pump inhibitors
- Dinoflagellates (p. 236)
- Plant toxins (p. 237)
- Heavy metals
- Ciguatera fish poisoning (p. 236)
- Scombrototoxic fish poisoning (p. 237)

(5-HT = 5-hydroxytryptamine, serotonin; NSAIDs = non-steroidal anti-inflammatory drugs; VIP = vasoactive intestinal peptide)

### 13.11 Infectious diarrhoea in old age

- **Incidence:** not increased but the impact is greater.
- **Mortality:** most deaths due to gastroenteritis in high-income countries are in adults aged over 70. Most are presumed to be caused by dehydration leading to organ failure.
- ***Clostridioides difficile* infection (CDI):** more common, especially in hospital and nursing home settings, usually following antibiotic exposure.

small bowel dysfunction). In general, the time from ingestion to the onset of symptoms is short and, other than dehydration, little systemic upset occurs. Other organisms, such as *Shigella* spp., *Campylobacter* spp. and enterohaemorrhagic *Escherichia coli* (EHEC), may directly invade the mucosa of the small bowel or produce cytotoxins that cause mucosal ulceration, typically affecting the terminal small bowel and colon. The incubation period is longer and more systemic upset occurs, with prolonged bloody diarrhoea. *Salmonella* spp. are capable of invading enterocytes and of causing both a secretory response and invasive disease with systemic features. This is seen with *Salmonella* Typhi and *Salmonella* Paratyphi (enteric fever without diarrhoea), but may occasionally be seen with other non-typhoidal *Salmonella* spp., particularly in the immunocompromised host and older people.

#### Clinical assessment

The history should address foods ingested (Box 13.12), duration and frequency of diarrhoea, presence of blood or steatorrhoea, abdominal pain and tenesmus, and whether other people have been affected. Fever and bloody diarrhoea suggest an invasive, colitic, dysenteric process. An incubation period of less than 18 hours suggests toxin-mediated food poisoning, and longer than 5 days suggests diarrhoea caused by protozoa or helminths. Person-to-person spread suggests infections, such as shigellosis or cholera.

Examination including assessment of the degree of dehydration such as thirst, headache, altered skin turgor, dry mucous membranes and postural hypotension, is important, particularly in tropical regions, where dehydration progresses rapidly. Signs of more marked dehydration include supine hypotension and tachycardia, decreased urinary output,

### 13.12 Foods associated with infectious illness, including gastroenteritis

#### Raw seafood

- Norovirus
- *Vibrio* spp.
- Hepatitis A

#### Raw eggs

- *Salmonella* serovars

#### Under-cooked meat or poultry

- *Salmonella* serovars
- *Campylobacter* spp.
- EHEC
- Hepatitis E (pork products)
- *Clostridium perfringens*

#### Unpasteurised milk or juice

- *Salmonella* serovars
- *Campylobacter* spp.
- EHEC
- *Yersinia enterocolitica*

#### Unpasteurised soft cheeses

- *Salmonella* serovars
- *Campylobacter* spp.
- ETEC
- *Yersinia enterocolitica*
- *Listeria monocytogenes*

#### Home-made canned goods

- *Clostridium botulinum*

#### Raw hot dogs, pâté

- *Listeria monocytogenes*

(EHEC = enterohaemorrhagic *Escherichia coli*; ETEC = enterotoxigenic *E. coli*)

delirium and sunken eyes. The blood pressure, pulse rate, urine output and ongoing stool losses should be monitored closely.

The severity of diarrhoea may be assessed by reference to the Bristol stool form scale (Bristol stool chart), which allows an objective assessment of stool consistency by providing a verbal and visual reference scale (Fig. 13.6). The Bristol stool form scale guides (at least in UK hospitals) decisions on stool sampling and infection prevention precautions in hospital inpatients, especially in relation to *C. difficile*.

#### Investigations

These include stool inspection for blood and microscopy for leucocytes, and also an examination for ova, cysts and parasites if the history indicates residence or travel to areas where these infections are prevalent. Stool culture should be performed and *C. difficile* toxin sought. FBC and serum electrolytes indicate the degree of inflammation and dehydration. Where cholera is prevalent, examination of a wet film with dark-field microscopy for darting motility aids diagnosis. In a malarious area, a blood film for malaria parasites should be obtained. Blood and urine cultures and a chest X-ray may identify alternative sites of infection, particularly if the clinical features suggest a syndrome other than gastroenteritis.

#### Management

All patients with acute, potentially infective diarrhoea should be appropriately isolated to minimise person-to-person spread of infection. If the history suggests a food-borne source, public health measures must be implemented to identify the source and to establish whether other linked cases exist.

#### Fluid replacement

Replacement of fluid losses in diarrhoeal illness is crucial and may be life-saving.

Normal daily fluid intake in an adult is only 1–2L, but there is considerable additional fluid movement in and out of the gut in secretions (see Fig. 23.7). Altered gut resorption with diarrhoea causes substantial isotonic fluid loss; up to 10–20L per day in cholera. Water and electrolytes need to be replaced, but electrolyte absorption from the gut is an active

**Fig. 13.6 Bristol stool chart.** The stool is given a 'score' of 1–7 by reference to the verbal and visual description. This is recorded on a chart (usually known as a 'Bristol stool chart') or in a patient monitoring database. Adapted from Lewis SJ, Heaton KW. Stool form scale as a useful guide to intestinal transit time. *Scand J Gastroenterol* 1997; 32:920–924.

energy-requiring process. Infected mucosa is capable of very rapid fluid and electrolyte transport if carbohydrate is available as an energy source. Oral rehydration solutions (ORS) therefore contain sugars, as well as water and electrolytes (Box 13.13). ORS are as effective as intravenous replacement fluid, even for cholera. In mild to moderate gastroenteritis, adults should be encouraged to drink fluids and continue normal dietary food intake. If this is impossible – due to vomiting, for example – intravenous fluid administration is required. In very sick patients or those with cardiac or renal disease, monitoring of urine output and central venous pressure may be necessary.

The volume of fluid replacement required should be estimated based on the following considerations:

- **Replacement of established deficit.** The average adult's diarrhoeal stool accounts for a loss of 200 mL of isotonic fluid. After 48 hours of moderate diarrhoea (6–10 stools per 24 hours), the average adult will be 2–4 L depleted. This requires rapid replacement of 1–1.5 L, either orally (ORS) or by intravenous infusion (normal saline), within the first 2–4 hours of presentation. Longer symptomatology, additional vomiting or more persistent/severe diarrhoea rapidly produces fluid losses comparable to diabetic ketoacidosis and is a metabolic emergency requiring active intervention.
- **Replacement of ongoing losses.** Stool losses should be accurately recorded and an estimate of ongoing losses calculated. Commercially available rehydration sachets provide 200 mL of ORS; one sachet per diarrhoea stool replaces losses.

### 13.13 Composition of oral rehydration solution and other replacement fluids\*

Fluid	Na	K	Cl	Energy
WHO	90	20	80	54
Dioralyte	60	20	60	71
Pepsi	6.5	0.8	–	400
7UP	7.5	0.2	–	320
Apple juice	0.4	26	–	480
Orange juice	0.2	49	–	400
Breast milk	22	36	28	670

\*Values given in mmol/L for electrolyte and kcal/L for energy components. (WHO = World Health Organization)

- **Replacement of normal daily requirement.** The average adult has a daily requirement of 1–1.5 L of fluid in addition to the calculations above. This will be increased substantially in fever or a hot environment.

#### Antimicrobial agents

In non-specific gastroenteritis, routine use of antimicrobials does not improve outcome and may lead to antimicrobial resistance or side-effects. They are usually used where there is systemic involvement, immunocompromise or significant comorbidity.

Evidence suggests that, in EHEC infections, antibiotics should not be used since they can enhance haemolytic uraemic syndrome (HUS; p. 582) due to increased toxin release.

Conversely, antibiotics are indicated in *Shigella dysenteriae* infection and in invasive salmonellosis – in particular, typhoid fever. Antibiotics may also be advantageous in cholera epidemics, reducing infectivity and controlling infection spread.

#### Antidiarrhoeal, antimotility and antisecretory agents

These agents are not recommended in acute infective diarrhoea. Loperamide, diphenoxylate and opiates are potentially dangerous in dysentery in childhood, causing intussusception. Antisecretory agents, such as bismuth and chlorpromazine, may make the stools appear bulkier but do not reduce stool fluid losses and may cause significant sedation. Adsorbents, such as kaolin or charcoal, have little effect.

### Non-infectious causes of food poisoning

Although less common non-infectious causes must also be considered in the differential diagnosis of gastroenteritis. These are discussed on page 236.

### Antimicrobial-associated diarrhoea

Antimicrobial-associated diarrhoea (AAD) is a common complication of antimicrobial therapy, especially with broad-spectrum agents. It is most common in older people but can occur at all ages. Although the specific mechanism is unknown in most cases of AAD, *C. difficile* is implicated in 20%–25% of cases and is the most common cause among patients with evidence of colitis. *Clostridium perfringens* is a rarer cause that usually remains undiagnosed, and *Klebsiella oxytoca* may also cause antibiotic-associated haemorrhagic colitis.

### Infections acquired in the tropics

Recent decades have seen unprecedented increases in long-distance travel, as well as extensive migration. Some infections maintain a fixed geographical distribution, being dependent on specific vectors or weather conditions, while others move with their human hosts and some

**13.14 How to assess health needs in travellers before departure\***

- Destination
- Personal details, including previous travel experience
- Dates of trip
- Itinerary and purpose of trip
- Personal medical history, including pregnancy, medication and allergies (e.g. to eggs, vaccines, antibiotics)
- Past vaccinations:
  - Childhood schedule followed? Diphtheria, tetanus, pertussis, polio, *Neisseria meningitidis* types B/C, *Haemophilus influenzae* B (HiB)
  - Travel-related? Typhoid, yellow fever, hepatitis A, hepatitis B, meningococcal ACW135Y, rabies, Japanese B encephalitis, tick-borne encephalitis
- Malaria prophylaxis: questions influencing the choice of antimalarial drugs are destination, past experience with antimalarials, history of epilepsy or psychiatric illness

\*Further information is available at [fitfortravel.nhs.uk](http://fitfortravel.nhs.uk).

may then be transmitted to other people. This means that the pattern of infectious diseases seen in each country changes constantly, and travel history and information on countries previously lived in, particularly during childhood, are crucial.

In general, the diversity of infectious diseases is greater in tropical than in temperate countries, and people in temperate countries have immunity to a narrower range of infections, reflecting less exposure in childhood and less ongoing boosting of immunity later in life, so that the most common travel-associated infections are those that are acquired by residents of temperate countries during visits to the tropics. In addition, those who have lived in tropical areas may lose immunity when they move to temperate countries and become susceptible when visiting their homeland.

Most travel-associated infections are preventable. Pre-travel advice is tailored to the destination and the traveller (Box 13.14). It includes avoidance of insect bites (using at least 20% diethyltoluamide (DEET)), sun protection (sunscreen with a sun protection factor (SPF) of at least 15), food and water hygiene ('Boil it, cook it, peel it or forget it!'), how to respond to travellers' diarrhoea (seek medical advice if bloody or if it lasts more than 48 hours) and, if relevant, safe sex (condom use).

### Fever acquired in tropical regions

Presentation with unexplained fever is common in travellers who are visiting or have recently travelled to tropical areas. Fever may also occur in those living in tropical regions if they lack immunity to endemic pathogens or if immunity is compromised by factors such as pregnancy. Common causes are malaria, enteric fever, viral hepatitis and dengue fever. Travellers to affected areas may have viral haemorrhagic fevers (VHFs) such as Ebola, Lassa, Crimean–Congo and Marburg (see Box 13.35), avian influenza (H5N1) or Middle East respiratory syndrome (MERS), which require special isolation precautions (High Consequence Infectious Diseases; HCID).

#### Clinical assessment

The approach to unexplained fever is as described above and key questions relating to infections acquired in tropical regions are listed in Box 13.15. Medicines purchased in some countries may have reduced efficacy, e.g. for malaria prophylaxis. Consult reliable up-to-date sources about resistance to antimalarial drugs in the country visited. Vaccinations against yellow fever and hepatitis A and B are sufficiently effective to virtually exclude these infections. Oral and injectable typhoid vaccinations are 70%–90% effective.

The differential diagnosis is guided by the clinical scenario, presence of specific exposures (Box 13.16) and incubation period (Box 13.17). *Falciparum* malaria typically presents 7–28 days after exposure. VHF, dengue and rickettsial infection can usually be excluded if more than 21 days have passed between leaving the area and onset of illness.

**13.15 How to obtain a history from travellers to the tropics with fever**

Questions	Factors to ascertain
<b>Countries visited and dates of travel</b>	Relate travel to known outbreaks of infection or antimicrobial resistance
<b>Determine the environment visited</b>	Travel to rural environments, forests, rivers or lakes
<b>Clarify where the person slept</b>	Sleeping in huts, use of bed nets, sleeping on the ground
<b>Establish what he/she was doing</b>	Exposure to people with medical illness, animals, soil, lakes and rivers
<b>History of insect bites</b>	Type of insect responsible, circumstances (location, time of day etc.), preventative measures
<b>Dietary history</b>	Ingestion of uncooked foods, salads and vegetables, meats (especially if undercooked), shellfish, molluscs, unpasteurised dairy products, unbottled water and sites at which food prepared
<b>Sexual history</b>	History of sexual intercourse with commercial sex workers, local population or travellers from other countries
<b>Malaria prophylaxis</b>	Type of prophylaxis
<b>Vaccination history</b>	Receipt of pre-travel vaccines and appropriateness to area visited
<b>History of any treatments received while abroad</b>	Receipt of medicines, local remedies, blood transfusions or surgical procedures

Clinical examination is summarised on page 262. Particular attention should be paid to the skin, throat, eyes, nail beds, lymph nodes, abdomen and heart. Patients may be unaware of tick bites or eschars. Body temperature should be measured at least twice daily.

#### Investigations and management

Initial investigations include blood films and a rapid diagnostic test (RDT; antigen detection) for malaria parasites, FBC, urinalysis and chest X-ray if indicated. Box 13.18 lists diagnoses and investigations to consider in unexplained acute fever.

Management is directed at the underlying cause. In patients with suspected HCID, such as VHF, strict infection control measures with isolation and barrier nursing are implemented to prevent contact with the patient's body fluids. The risk of VHF should be determined using epidemiological risk factors and clinical signs (Fig. 13.7), and further management undertaken as described in this chapter.

#### Diarrhoea acquired in the tropics

Gastrointestinal illness is the most common infection amongst visitors to the tropics, with *Salmonella* spp., *Campylobacter* spp. and *Cryptosporidium* spp. infections prevalent worldwide (Box 13.19). *Shigella* spp. and *Entamoeba histolytica* (amoebiasis) are usually acquired in South Asia or sub-Saharan and southern Africa.

The approach to patients with acute diarrhoea is described on page 272. The benefits of treating travellers' diarrhoea with antimicrobials are marginal, with slight reductions in stool frequency and likelihood of cure at 72 hours offset by increased side-effects. The differential diagnosis of diarrhoea persisting for more than 14 days is wide (see Box 23.19). The differential of chronic diarrhoea includes parasitic and bacterial causes, tropical malabsorption, inflammatory bowel disease and neoplasia. Causes particularly associated with the tropics include giardiasis, strongyloidiasis, chronic intestinal schistosomiasis, intestinal flukes, enteropathogenic *E. coli*, HIV enteropathy, hypolactasia (lactase

13.16 Specific exposures and causes of fever in the tropics	
Exposure	Infection or disease
Mosquito bite	Malaria, dengue fever, chikungunya, filariasis, tularaemia
Tsetse fly bite	African trypanosomiasis
Tick bite	Rickettsial infections including typhus, Lyme disease, tularaemia, Crimean–Congo haemorrhagic fever, Kyasanur forest disease, babesiosis, tick-borne encephalitis
Louse bite	Typhus
Flea bite	Plague
Sandfly bite	Leishmaniasis, arbovirus infection
Reduviid bug	Chagas' disease
Animal contact	Q fever, brucellosis, anthrax, plague, tularaemia, viral haemorrhagic fevers, rabies
Freshwater swimming	Schistosomiasis, leptospirosis, <i>Naegleria fowleri</i>
Exposure to soil	Inhalation: dimorphic fungi Inhalation or inoculation: <i>Burkholderia pseudomallei</i> Inoculation (most often when barefoot): hookworms, <i>Strongyloides stercoralis</i>
Raw or under-cooked fruit and vegetables	Enteric bacterial infections, hepatitis A or E virus, <i>Fasciola hepatica</i> , <i>Toxocara</i> spp., <i>Echinococcus granulosus</i> (hydatid disease), <i>Entamoeba histolytica</i>
Under-cooked pork	<i>Taenia solium</i> (cysticercosis)
Crustaceans or molluscs	Paragonimiasis, gnathostomiasis, <i>Angiostrongylus cantonensis</i> infection, hepatitis A virus, cholera
Unpasteurised dairy products	Brucellosis, salmonellosis, abdominal tuberculosis, listeriosis
Untreated water	Enteric bacterial infections, giardiasis, <i>Cryptosporidium</i> spp. (chronic in immunocompromised), hepatitis A or E virus

deficiency) and chronic calcific pancreatitis. The workup should include tests for parasitic causes of chronic diarrhoea, such as examination of stool and duodenal aspirates for ova and parasites, and serological investigation.

*Giardia lamblia* infection (giardiasis) may progress to a malabsorption syndrome. If no cause is found, empirical treatment for giardiasis with metronidazole is often helpful.

HIV-1 may cause chronic diarrhoea due to medications or infection. Causes such as HIV enteropathy or infection with agents such as *Cryptosporidium* spp., *Cystoisospora belli* or microsporidia are uncommon once antiretroviral therapy is commenced, and AIDS-associated diarrhoea due to CMV or disseminated *Mycobacterium avium* complex infection is uncommon in tropical regions.

### Eosinophilia acquired in the tropics

Eosinophilia occurs in a variety of haematological, allergic and inflammatory conditions discussed on page 935. It may also arise in HIV-1 and human T-cell lymphotropic virus (HTLV)-1 infection. However, eosinophils are important in the immune response to parasitic infections, especially those with a tissue migration phase. In the context of travel to or residence in the tropics, a patient with an eosinophil count of more than

0.4 × 10<sup>9</sup>/L should be investigated for both non-parasitic (see [Box 25.9](#)) and parasitic causes ([Box 13.20](#)).

The response to parasite infections is often different when travellers to and residents of endemic areas are compared. Travellers often have recent and light infections associated with eosinophilia. Residents who have been infected for a long time often have chronic pathology without eosinophilia.

### Clinical assessment

A history of travel to known endemic areas for schistosomiasis, onchocerciasis and the filariases will indicate possible causes. Assessment

13.18 Investigation of tropically acquired acute fever without localising signs	
Features on full blood count	Further investigations
<b>Neutrophil leucocytosis</b>	
Bacterial sepsis	Blood culture
Leptospirosis	Culture of blood and urine, serology
Borreliosis (tick- or louse-borne relapsing fever)	Blood film
Amoebic liver abscess	Ultrasound
<b>Normal white cell count and differential</b>	
Malaria (may have low platelets or anaemia)	Blood film, antigen test
Typhoid fever	Blood and stool culture
Typhus	Serology
<b>Lymphocytosis</b>	
Viral fevers, including VHF	Serology, PCR
Infectious mononucleosis	Monospot test, serology
Malaria	Blood film, antigen test
Rickettsial fevers	Serology
<b>Atypical lymphocytes</b>	
Dengue and other VHF	Serology, antigen, PCR
Infectious mononucleosis-like syndromes	Serology, PCR
HIV (acute retroviral syndrome)	Serology, antigen
Hepatitis viruses	Serology, antigen, PCR
Parasitic, malaria, trypanosomiasis	Blood film, antigen test, PCR
(HIV = human immunodeficiency virus; PCR = polymerase chain reaction; VHF = viral haemorrhagic fever)	

should establish duration of exposure and the history should address all the elements in [Box 13.15](#).

Physical signs or symptoms that suggest a parasitic cause for eosinophilia include transient rashes (schistosomiasis or strongyloidiasis), fever (Katayama syndrome), pruritus (onchocerciasis) or migrating subcutaneous swellings (loiasis, gnathostomiasis) (see [Box 13.21](#)). Paragonimiasis can give rise to haemoptysis, and the migratory phase of intestinal nematodes or lymphatic filariasis may cause cough, wheezing and transient pulmonary infiltrates. Schistosomiasis, strongyloidiasis and gnathostomiasis induce transient respiratory symptoms with infiltrates in the acute stages and, when eggs reach the pulmonary vasculature in chronic schistosomiasis infection, can result in shortness of breath with features of right heart failure due to pulmonary hypertension. Fever and hepatosplenomegaly are seen in schistosomiasis, *Fasciola hepatica* infection and toxocarasis (visceral larva migrans). Intestinal worms, such as

13.19 Most common causes of travellers' diarrhoea	
•	Enterotoxigenic <i>E. coli</i> (ETEC)
•	<i>Shigella</i> spp.
•	<i>Campylobacter jejuni</i>
•	<i>Salmonella</i> serovars
•	<i>Plesiomonas shigelloides</i>
•	Non-cholera <i>Vibrio</i> spp.
•	<i>Aeromonas</i> spp.

*Ascaris lumbricoides* and *Strongyloides stercoralis*, can cause abdominal symptoms, including intestinal obstruction and diarrhoea. In the case of heavy infestation with *Ascaris*, this may be due to fat malabsorption and there may be associated nutritional deficits. *Schistosoma haematobium* can cause haematuria or haematospermia. *Toxocara* spp. can give rise to choroidal lesions with visual field defects. *Angiostrongylus cantonensis* and gnathostomiasis induce eosinophilic meningitis, and the hyperinfection syndrome caused by *S. stercoralis* in immunocompromised hosts induces meningitis due to Gram-negative bacteria. Myositis is a feature of trichinosis (trichinellosis) and cysticercosis. Periorbital oedema can occur with trichinosis.

### Investigations

The diagnosis of a parasitic infestation requires direct visualisation of adult worms, larvae or ova. Serum antibody detection may not distinguish between active and past infection and is often unhelpful in those born in endemic areas. Radiological investigations may provide circumstantial evidence of parasite infestation. [Box 13.21](#) describes initial investigations for eosinophilia.

### Management

A specific diagnosis guides therapy. In the absence of a specific diagnosis, many clinicians will give an empirical course of praziquantel if the individual has potentially been exposed to schistosomiasis, or with albendazole/ivermectin if strongyloidiasis or intestinal nematodes are likely causes.

## Skin conditions acquired in the tropics

Community-based studies in the tropics consistently show that skin infections (bacterial and fungal), scabies and eczema are the most common skin problems ([Box 13.22](#)). Scabies and eczema are discussed on pages 1093 and 1096. Cutaneous leishmaniasis and onchocerciasis have defined geographical distributions. In travellers, secondarily infected insect bites, pyoderma, cutaneous larva migrans and non-specific dermatitis are common.

**Fig. 13.7** Approach to the patient with suspected viral haemorrhagic fever (VHF). See [Box 13.35](#). \*Epidemiological risk factors: staying with a febrile individual, caring for a sick individual, or contact with body fluids from a suspected human or animal case of VHF. (PCR = polymerase chain reaction)

13.20 Parasite infections that cause eosinophilia		
Infestation	Pathogen	Clinical syndrome with eosinophilia
<b>Strongyloidiasis</b>	<i>Strongyloides stercoralis</i>	Larva currens
<b>Soil-transmitted helminthiasis</b>		
Hookworm	<i>Necator americanus</i> <i>Ancylostoma duodenale</i>	Anaemia Anaemia
Ascariasis	<i>Ascaris lumbricoides</i>	Löffler syndrome
Toxocariasis	<i>Toxocara canis</i>	Visceral larva migrans
<b>Schistosomiasis</b>		
	<i>Schistosoma haematobium</i> <i>S. mansoni</i> , <i>S. japonicum</i>	Katayama fever  Chronic infection
<b>Filariases</b>		
Loiasis	<i>Loa loa</i>	Skin nodules
<i>Wuchereria bancrofti</i>	<i>W. bancrofti</i>	Lymphangitis, lymphadenopathy, orchitis, intermittent bouts of cellulitis, lymphoedema and elephantiasis
<i>Brugia malayi</i>	<i>B. malayi</i>	Brugian elephantiasis similar but typically less severe than that caused by <i>W. bancrofti</i>
<i>Mansonella perstans</i>	<i>M. perstans</i>	Asymptomatic infection, occasionally subconjunctival nodules
Onchocerciasis	<i>Onchocerca volvulus</i>	Visual disturbance, dermatitis
<b>Other nematode infections</b>		
	<i>Trichinella spiralis</i> <i>Gnathostoma spinigerum</i>	Myositis Pruritus, migratory nodules, eosinophilic meningitis
<b>Cestode infections</b>		
	<i>Taenia saginata</i> , <i>T. solium</i>  <i>Echinococcus granulosus</i>	Usually asymptomatic; eosinophilia associated with migratory phase Lesions in liver or other organ; eosinophilia associated with leakage from cyst
<b>Liver flukes</b>		
	<i>Fasciola hepatica</i>  <i>Clonorchis sinensis</i> <i>Opisthorchis felineus</i>	Hepatic symptoms; eosinophilia associated with migratory phase As for fascioliasis As for fascioliasis
<b>Lung fluke</b>		
	<i>Paragonimus westermani</i>	Lung lesions

During the investigation of skin lesions, enquiry should be made about habitation, activities undertaken and regions visited (see Box 13.15). Examples of skin lesions in tropical disease are shown in Figure 13.8.

Skin biopsies are helpful in diagnosing aetiology. Culture of biopsy material may be needed to diagnose bacterial, fungal, parasitic and mycobacterial infections.

## Infections in adolescence

Particular issues of relevance in adolescent patients are shown in Box 13.23.

13.21 Initial investigation of eosinophilia	
Investigation	Pathogens sought
<b>Stool microscopy</b>	Ova, cysts and parasites
<b>Terminal urine</b>	Ova of <i>Schistosoma haematobium</i>

### 13.23 Key issues in infectious diseases in adolescence

- **Common infectious syndromes:** infectious mononucleosis, bacterial pharyngitis, whooping cough, pneumonia, staphylococcal skin/soft tissue infections, urinary tract infections, acute gastroenteritis.
- **Life-threatening infections:** meningococcal infection (sepsis and/or meningitis).
- **Sexually transmitted infections:** human papillomavirus (HPV), human immunodeficiency virus-1 (HIV-1), hepatitis B virus and chlamydia. These may reflect either voluntary sexual activity or sexual coercion/abuse.
- **Travel-related infections:** diarrhoea, malaria etc. are relatively common.
- **Infections in susceptible groups:** patients with cystic fibrosis, congenital immunodeficiency, acute leukaemia and other adolescent malignancies are vulnerable to specific groups of infections.
- **Infections requiring prolonged antimicrobial use:** adherence to chronic therapy is challenging, for both oral (antituberculous or antiretroviral) and systemic (osteomyelitis, septic arthritis or post-operative infections) treatments. Outpatient antimicrobial therapy is preferred to minimise hospitalisation.
- **Vaccination:** engagement with age-specific vaccine programmes should be ensured, e.g. HPV, childhood booster vaccines and meningococcal vaccine.
- **Risk reduction:** education relating to sexual health and alcohol and recreational drug usage is important.

## Infections in pregnancy

Box 13.24 shows some of the infections encountered in pregnancy.

## Viral infections

### Systemic viral infections with exanthem

Childhood exanthems are characterised by fever and widespread rash. Maternal antibody usually gives protection for the first 6–12 months of life. Comprehensive immunisation programmes have dramatically reduced the number of paediatric infections but incomplete uptake results in infections in later life.

### Measles

The World Health Organization (WHO) has set the objective of eradicating measles globally using the live attenuated vaccine. However, vaccination of more than 95% of the population is required to prevent outbreaks due

to the high basic reproduction number ( $R_0$  value; see p. 108). Clusters of infection in young adults are associated with mass gatherings, e.g. music festivals and sub-populations with lower vaccination coverage. Natural illness produces life-long immunity.

### Clinical features

Infection is by respiratory droplets with an incubation period of 6–19 days. A prodromal illness occurs, 1–3 days before the rash, with upper respiratory symptoms, conjunctivitis and the presence of the pathognomonic Koplik's spots: small white spots surrounded by erythema on the buccal mucosa (Fig. 13.9A). As natural antibody develops, the maculopapular rash appears, spreading from the face to the extremities (Fig. 13.9B). Generalised lymphadenopathy and diarrhoea are common. Complications are more common in older children and adults, and include otitis media, bacterial pneumonia, transient hepatitis, pancreatitis and clinical encephalitis (approximately 0.1% of cases). A rare late complication is subacute sclerosing panencephalitis (SSPE), which occurs up to 7 years after infection (see Ch. 28).

Measles is a serious disease in the malnourished, vitamin-deficient or immunocompromised. Persistent infection with a giant cell pneumonitis or encephalitis may occur but rash may be absent. In tuberculosis infection, measles suppresses cell-mediated immunity and may exacerbate disease; for this reason, measles vaccination should be deferred until after commencing antituberculous treatment. Measles does not cause congenital malformation but may be more severe in pregnant women.

Mortality clusters at the extremes of age and is highly dependent on health economic status. In 2018 there were approximately 15 deaths per 1000 cases globally, ranging from 0.2:1000 in Europe to 30:1000 in the Africa region (WHO data). Death usually results from a bacterial superinfection, occurring as a complication of measles: most often pneumonia, diarrhoeal disease or noma/cancrum oris, a gangrenous stomatitis. Death may also result from complications of measles encephalitis.

### Diagnosis

Clinical diagnosis is challenging but supported by detection of antibodies (immunoglobulin (Ig) M and IgG) and/or measles RNA in oral fluid. It is a notifiable disease in the UK.

### Management and prevention

Immunoglobulin therapy attenuates the disease in the immunocompromised (regardless of vaccination status) and in non-immune pregnant women, but must be given within 6 days of exposure. Vaccination can be used in outbreaks and vitamin A may improve the outcome in uncomplicated disease. Antibiotic therapy is reserved for bacterial complications. In the UK children are offered vaccination with a combined measles, mumps and rubella vaccine (MMR; a live attenuated vaccine) at 1 year of age, with a pre-school booster at 3 years 4 months.

### Rubella (German measles)

Rubella causes exanthem in the non-immunised.

### Clinical features

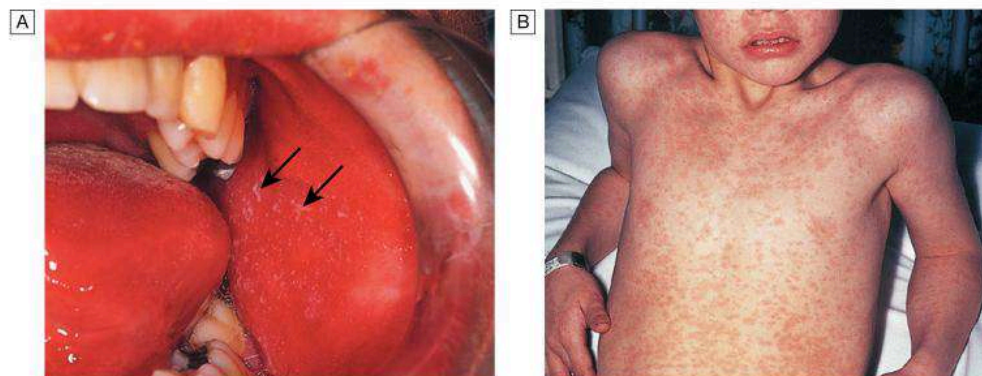

Rubella is spread by respiratory droplet, with infectivity from up to 10 days before to 2 weeks after the onset of the rash. The incubation period is 15–20 days. In childhood, most cases are subclinical, although clinical features may include fever, maculopapular rash spreading from the face, and lymphadenopathy. Complications are rare but include thrombocytopenia and hepatitis. Encephalitis and haemorrhage are occasionally reported. In adults, arthritis involving hands or knees is relatively common, especially in women.

If transplacental infection takes place in the first trimester or later, persistence of the virus is likely and severe congenital disease may result (Box 13.25). Even if normal at birth, there is an increased incidence of other diseases, e.g. diabetes mellitus, later in life.

### Diagnosis

Laboratory confirmation of rubella is required if there has been contact with a pregnant woman. This is achieved either by detection of rubella

13.24 Infections of specific importance in pregnancy		
Infection	Consequence	Prevention and management
Rubella	Congenital malformation	Childhood vaccination and vaccination of non-immune mothers post-delivery
Cytomegalovirus	Neonatal infection, congenital malformation	Limited prevention strategies
Zika virus	Congenital malformation	Avoidance of travel, delay in pregnancy if infected
Varicella zoster (VZ) virus	Neonatal infection, congenital malformation, severe infection in mother	VZ immunoglobulin, antiviral prophylaxis (see Box 13.29)
Herpes simplex virus (HSV)	Congenital or neonatal infection	Aciclovir and consideration of caesarean section for mothers who shed HSV from genital tract at time of delivery. Aciclovir for infected neonates
Hepatitis B virus	Chronic infection of neonate	Hepatitis B immunoglobulin and active vaccination of newborn
Hepatitis E virus	Fulminant hepatitis, pre-term delivery, fetal loss	Maintenance of standard food hygiene practices
Human immunodeficiency virus-1 (HIV-1)	Chronic infection of neonate	Antiretroviral drugs for mother and infant and consideration of caesarean section if HIV-1 viral load detectable. Avoidance of breastfeeding
Parvovirus B19	Congenital infection	Avoidance of individuals with acute infection if pregnant
Measles	More severe infection in mother and neonate, fetal loss	Childhood vaccination, human normal immunoglobulin in non-immune pregnant contacts and vaccination post-delivery
Dengue	Neonatal dengue if mother has infection <5 weeks prior to delivery	Vector (mosquito) control
Syphilis	Congenital malformation	Serological testing in pregnancy with prompt treatment of infected mothers
<i>Neisseria gonorrhoeae</i> and <i>Chlamydia trachomatis</i>	Neonatal conjunctivitis (ophthalmia neonatorum, see Ch. 15)	Treatment of infection in mother and neonate
Listeriosis	Neonatal meningitis or bacteraemia, bacteraemia or pyrexia of unknown origin in mother	Avoidance of unpasteurised cheeses and other dietary sources
Brucellosis	Possibly increased incidence of fetal loss	Avoidance of unpasteurised dairy products
Group B streptococcal infection	Neonatal meningitis and sepsis. Sepsis in mother after delivery	Risk- or screening-based antimicrobial prophylaxis in labour (recommendations vary between countries)
Toxoplasmosis	Congenital malformation	Diagnosis and prompt treatment of cases, avoidance of under-cooked meat while pregnant
Malaria	Fetal loss, intrauterine growth retardation, severe malaria in mother	Avoidance of insect bites. Intermittent preventative treatment during pregnancy to decrease incidence in high-risk countries

**Fig. 13.9** Measles. **A** Koplik's spots (arrows) seen on buccal mucosa in the early stages of clinical measles. **B** Typical measles rash.

IgM in serum or by IgG seroconversion. In the exposed pregnant woman, absence of rubella-specific IgG confirms the potential for congenital infection.

### Prevention

All children should be immunised with MMR vaccine. Congenital rubella syndrome may be controlled by testing women of child-bearing age for rubella antibodies and offering vaccination if seronegative. Antenatal rubella screening for pregnant mothers in the UK ceased in 2016 because of the rarity of rubella in the target population.

### Parvovirus B19

Parvovirus B19 causes exanthem and other clinical syndromes. Some 50% of children and 60%–90% of adults are seropositive. Most infections are spread by the respiratory route, although spread via contaminated blood is also possible. The virus has particular tropism for red cell precursors.

### Clinical features

Many infections are subclinical. Clinical manifestations result after an incubation period of 14–21 days (Box 13.26). The classic exanthem

13.25 Rubella infection: risk of congenital malformation	
Stage of gestation	Likelihood of malformations
1–2 months	65%–85% chance of illness, multiple defects/spontaneous abortion
3 months	30%–35% chance of illness, usually a single congenital defect (most frequently deafness, cataract, glaucoma, mental retardation or congenital heart disease, especially pulmonary stenosis or patent ductus arteriosus)
4 months	10% risk of congenital defects, most commonly deafness
> 20 weeks	Occasional deafness

13.26 Clinical features of parvovirus B19 infection	
Affected age group	Clinical manifestations
<b>Fifth disease (erythema infectiosum)</b>	
Small children	Three clinical stages: a 'slapped cheek' appearance, followed by a maculopapular rash progressing to a reticulate eruption on the body and limbs, then a final stage of resolution. Often the child is quite well throughout
<b>Gloves and socks syndrome</b>	
Young adults	Fever and an acral purpuric eruption with a clear margin at the wrists and ankles. Mucosal involvement also occurs
<b>Arthropathies</b>	
Adults and occasionally children	Symmetrical small-joint polyarthropathy. In children it tends to involve the larger joints in an asymmetrical distribution
<b>Impaired erythropoiesis</b>	
Adults, those with haematological disease, the immunosuppressed	Mild anaemia; in an individual with an underlying haematological abnormality it can precipitate transient aplastic crisis, or in the immunocompromised a more sustained but often milder pure red cell aplasia
<b>Hydrops fetalis</b>	
Transplacental fetal infection	Asymptomatic or symptomatic maternal infection that can cause fetal anaemia with an aplastic crisis, leading to non-immune hydrops fetalis and spontaneous abortion

(erythema infectiosum) is preceded by a prodromal fever and coryzal symptoms. A 'slapped cheek' rash is characteristic (Fig. 13.10) but the rash is very variable, including 'glove and stocking'. In adults, polyarthropathy is common. Infected individuals have a transient block in erythropoiesis for a few days. This is of no clinical consequence except in individuals with increased red cell turnover due to haemoglobinopathy or haemolytic anaemia, who develop an acute anaemia that may be severe (transient aplastic crisis). Erythropoiesis usually recovers spontaneously after 10–14 days. Immunocompromised individuals can develop a more sustained block in erythropoiesis in response to the chronic viraemia that results from their inability to clear the infection. Infection during the first two trimesters of pregnancy can result in intrauterine infection and impact on fetal bone marrow; it causes 10%–15% of non-immune (non-Rhesus-related) hydrops fetalis, a rare complication of pregnancy.

### Diagnosis

IgM to parvovirus B19 suggests recent infection but may persist for months and false positives occur. Seroconversion to IgG positivity confirms infection but in isolation a positive IgG is of little diagnostic utility.

Fig. 13.10 Slapped cheek syndrome. The typical facial rash of parvovirus B19 infection.

Detection of parvovirus B19 DNA in blood is particularly useful in immunocompromised patients. Giant pronormoblasts or haemophagocytosis may be demonstrable in the bone marrow.

### Management

Infection is usually self-limiting. Symptomatic relief for arthritic symptoms may be required. Severe anaemia requires transfusion. Persistent viraemia in immunocompromised hosts may require immunoglobulin therapy to clear the virus.

Pregnant women should avoid contact with parvovirus B19 infection; if they are exposed, serology should be performed to establish whether they are immune (IgG-positive).

Passive prophylaxis with immunoglobulin therapy has been suggested for non-immune pregnant women exposed to infection but there are limited data to support this recommendation. Pregnancy should be closely monitored by ultrasound scanning, so that hydrops fetalis can be treated by fetal transfusion.

## Human herpesvirus 6 and 7

Human herpesvirus 6 (HHV-6) is a lymphotropic virus that causes a childhood viral exanthem (exanthem subitum), rare cases of an infectious mononucleosis-like syndrome and infection in the immunocompromised host. Infection is almost universal, with approximately 95% of children acquiring this virus by 2 years of age. Transmission is via saliva.

HHV-7 is very closely related to HHV-6 and is believed to be responsible for a proportion of cases of exanthem subitum. Like HHV-6, HHV-7 causes an almost universal infection in childhood, with subsequent latent infection and occasional infection in the immunocompromised host.

### Clinical features

Exanthem subitum is also known as roseola infantum or sixth disease (Box 13.27). A high fever is followed by a maculopapular rash as the fever resolves. Fever and/or febrile convulsions may also occur without a rash. Rarely, older children or adults may develop an infectious mononucleosis-like illness, hepatitis or rash. In the immunocompromised, infection is rare but can cause fever, rash, hepatitis, pneumonitis, cytopenia or encephalitis.

### Diagnosis and management

Exanthem subitum is usually a clinical diagnosis but can be confirmed by antibody and/or DNA detection. The disease is self-limiting. Treatment with ganciclovir or foscarnet is used in immunocompromised hosts infected with HHV-6.

13.27 Herpesvirus infections	
Virus	Infection
<b>Herpes simplex virus (HSV)</b>	
HSV-1	Herpes labialis ('cold sores') Stomatitis, pharyngitis Corneal ulceration Finger infections ('whitlows') Eczema herpeticum Encephalitis
HSV-2	Genital ulceration and neonatal infection (acquired during vaginal delivery) Acute meningitis or transverse myelitis; rarely, encephalitis
<b>Varicella zoster virus (VZV)</b>	Chickenpox (varicella) Shingles (herpes zoster)
<b>Cytomegalovirus (CMV)</b>	Congenital infection Infectious mononucleosis (heterophile antibody-negative) Hepatitis Disease in immunocompromised patients: retinitis, encephalitis, pneumonitis, hepatitis, enteritis Fever with abnormalities in haematological parameters
<b>Epstein-Barr virus (EBV)</b>	Infectious mononucleosis Burkitt and other lymphomas Nasopharyngeal carcinoma Oral hairy leucoplakia (AIDS patients) Other lymphomas, post-transplant lymphoproliferative disorder
<b>Human herpesvirus 6 and 7 (HHV-6, HHV-7)</b>	Exanthem subitem Disease in immunocompromised patients
<b>Human herpesvirus 8 (HHV-8)</b>	Kaposi's sarcoma, primary effusion lymphoma, multicentric Castlemans disease

## Chickenpox (varicella)

Varicella zoster virus (VZV) is a dermatropic and neurotropic virus that produces primary infection, usually in childhood, which may reactivate in later life. VZV is spread by aerosol and direct contact. It is highly infectious to non-immune individuals. Disease in children is usually well tolerated. Manifestations are more severe in adults, pregnant women and the immunocompromised.

### Clinical features

The incubation period is 11–20 days, after which a vesicular eruption begins (Fig. 13.11), often on mucosal surfaces first, followed by rapid dissemination in a centripetal distribution (most dense on trunk and sparse on limbs). New lesions occur every 2–4 days and each crop is associated with fever. The rash progresses from small pink macules to vesicles and pustules within 24 hours. Infectivity lasts from up to 4 days (but usually 48 hours) before the lesions appear until the last vesicles crust over. Due to intense itching, secondary bacterial infection from scratching is the most common complication of primary chickenpox. Self-limiting cerebellar ataxia and encephalitis are rare complications.

Adults, pregnant women and the immunocompromised are at increased risk of visceral involvement, which presents as pneumonitis, hepatitis or encephalitis. Pneumonitis can be fatal and is more likely to occur in smokers. Maternal infection in early pregnancy carries up to 2% risk of neonatal damage with developmental abnormalities of eyes, CNS and limbs. Chickenpox within 5 days of delivery leads to severe neonatal varicella with visceral involvement and haemorrhage.

### Diagnosis

Diagnosis is primarily by recognition of the rash. If necessary, this can be confirmed by detection of antigen (direct immunofluorescence) or DNA in aspirated vesicular fluid. Serology is used to identify seronegative individuals at risk of infection.

### Management and prevention

The benefit of antivirals for uncomplicated primary VZV infection in children is marginal, shortening the duration of rash by only 1 day, and is not normally required. Antivirals are, however, used for uncomplicated chickenpox in adults when the patient presents within 24–48 hours of onset of vesicles, in all patients with complications, and in those who are immunocompromised, including pregnant women, regardless of duration of vesicles (Box 13.28). More severe disease, particularly in immunocompromised hosts, requires initial parenteral therapy. Immunocompromised patients may have prolonged viral shedding and may require prolonged treatment until all lesions crust over.

Post-exposure prophylaxis is used to attenuate infection in people who have had significant contact with VZV, are susceptible to infection (i.e. have no history of chickenpox or shingles and are seronegative for VZV IgG) and are at risk of severe disease (e.g. immunocompromised or pregnant) (Box 13.29). Shortages of human VZ immunoglobulin (VZIG) have resulted in greater use of antiviral prophylaxis. Ideally, where indicated, VZIG should be given within 7 days of exposure, but it may attenuate disease even if given up to 10 days afterwards. Susceptible contacts who develop severe chickenpox after receiving VZIG should be treated with antiviral therapy.

A live, attenuated VZV vaccine is available and in routine use in the USA and other countries, but in the UK its use is restricted to non-immune health-care workers and household contacts of immunocompromised individuals. Children receive one dose after 1 year of age and a second dose at 4–6 years of age; seronegative adults receive two doses at least 1 month apart. The vaccine may also be used prior to planned iatrogenic immunosuppression, e.g. before transplant and for people aged over 70 to prevent shingles.

## Shingles (herpes zoster)

After initial infection, VZV persists in latent form in the dorsal root ganglion of sensory nerves and can reactivate in later life.

### Clinical features

Burning discomfort occurs in the affected dermatome following reactivation and discrete vesicles appear 3–4 days later. Brief viraemia can produce distant satellite 'chickenpox' lesions. Occasionally, paraesthesia occurs without rash ('zoster sine herpete'). Severe disease, a prolonged duration of rash, multiple dermatomal involvement or recurrence suggests underlying immune deficiency. Chickenpox may be contracted from a case of shingles but not vice versa.

Although thoracic dermatomes are most commonly involved (see Fig. 13.11B), the ophthalmic division of the trigeminal nerve is also frequently affected; vesicles may appear on the cornea and lead to ulceration. This condition can lead to blindness and urgent ophthalmology review is required. Geniculate ganglion involvement causes the Ramsay Hunt syndrome of facial palsy, ipsilateral loss of taste and buccal ulceration, plus a rash in the external auditory canal. This may be mistaken for Bell's palsy, which is discussed on page 1140. Bowel and bladder dysfunction occur with sacral nerve root involvement. The virus occasionally causes cranial nerve palsy, myelitis or encephalitis. Granulomatous cerebellar angiitis is a cerebrovascular complication that leads to a stroke-like syndrome in association with shingles, especially in an ophthalmic distribution.

In post-herpetic neuralgia, pain from shingles persists for 3 months or longer following healing of the rash. It is more common with advanced age.

**Fig. 13.11** Varicella zoster virus infection. **A** Chickenpox. **B** Shingles in a thoracic dermatome.

### **i** 13.28 Therapy for herpes simplex and varicella zoster virus infection

Disease state	Treatment options
<b>Primary genital HSV</b>	Famciclovir 250 mg 3 times daily for 7–10 days Valaciclovir 1 g twice daily for 7–10 days Oral aciclovir 200 mg 5 times daily or 400 mg 3 times daily for 7–10 days
Severe and preventing oral intake	Aciclovir 5 mg/kg 3 times daily IV until patient can tolerate oral therapy
<b>Recurrent genital HSV-1 or 2</b>	Oral aciclovir 200 mg 5 times daily or 400 mg 3 times daily for 5 days Famciclovir 125 mg twice daily for 5 days Valaciclovir 500 mg twice daily for 3–5 days or 2 g twice daily for 1 day. Shorter durations increasingly favoured
<b>Primary or recurrent oral HSV</b>	Usually no treatment If required, usually short duration, e.g. valaciclovir 2 g twice daily for 1 day
<b>Mucocutaneous HSV infection in immunocompromised host</b>	Aciclovir 5 mg/kg 3 times daily IV for 7–10 days Oral aciclovir 400 mg 4 times daily for 7–10 days Famciclovir 500 mg 3 times daily for 7–10 days Valaciclovir 1 g twice daily for 7–10 days
<b>Chickenpox in adult or child</b>	Oral aciclovir 800 mg 5 times daily for 5 days Famciclovir 500 mg 3 times daily for 5 days Valaciclovir 1 g 3 times daily for 5 days
Immunocompromised host/pregnant woman	Aciclovir 5 mg/kg 3 times daily IV until patient is improving, then complete therapy with oral therapy until all lesions are crusting over
<b>Shingles</b>	Treatment and doses as for chickenpox but duration typically 7–10 days
<b>Visceral involvement (non-CNS) in HSV</b>	Aciclovir IV 5 mg/kg 3 times daily for 14 days
<b>Visceral involvement (non-CNS) in VZV</b>	Aciclovir IV 5 mg/kg 3 times daily for 7 days
<b>Severe complications</b> (encephalitis, disseminated infection)	Aciclovir IV 10 mg/kg 3 times daily (up to 20 mg/kg in neonates) for 14–21 days
<b>HSV disease suppression</b>	Aciclovir 400 mg twice daily Famciclovir 250 mg twice daily Valaciclovir 500 mg daily

(CNS = central nervous system; HSV = herpes simplex virus; IV = intravenous; VZV = varicella zoster virus)

### Management

Early therapy with aciclovir or related antivirals has been shown to reduce both early- and late-onset pain, especially in patients over 65 years. Post-herpetic neuralgia requires aggressive analgesia, along with agents such as amitriptyline 25–100 mg daily, gabapentin (commencing at 300 mg daily and building slowly to 300 mg twice daily or more) or pregabalin (commencing at 75 mg twice daily and building up to 100 mg or 200 mg 3 times daily if tolerated). Capsaicin cream (0.075%) may be helpful. Glucocorticoids have not been demonstrated to reduce post-herpetic neuralgia.

The zoster vaccine is a live attenuated vaccine with a higher dose of VZV than the chickenpox vaccine. It reduces the incidence of shingles and of post-herpetic neuralgia. It is recommended in the UK for people aged over 70 years. A recombinant vaccine is available in the USA.

### Enteroviral exanthems

Coxsackievirus or echovirus infections can lead to a maculopapular eruption or roseola-like rash that occurs after fever falls. Enteroviral infections are discussed further under viral infections of the skin (see below).

### Systemic viral infections without exanthem

Other systemic viral infections present with features other than a rash suggestive of exanthem. Rashes may occur in these conditions but differ from those seen in exanthems or are not the primary presenting feature.

### 13.29 Indications for varicella zoster post-exposure prophylaxis (UK guidance)

An adult should satisfy all three of the following conditions:

#### 1. Significant contact

Contact with chickenpox (any time from 48 hrs before the rash until crusting of lesions) or zoster (exposed, disseminated or, with immunocompromised contacts, localised zoster; between development of the rash until crusting) defined as:

- Prolonged household contact, sharing a room for  $\geq 15$  mins or face-to-face contact (includes direct contact with zoster lesions)
- Hospital contact with chickenpox in another patient, health-care worker or visitor
- Intimate contact (e.g. touching) with person with shingles lesions
- Newborn whose mother develops chickenpox no more than 5 days before delivery or 2 days after delivery

#### 2. Susceptible contact

- Individual with no history of chickenpox, ideally confirmed by negative test for VZV IgG

#### 3. Predisposition to severe chickenpox

- Immunocompromised due to disease (e.g. acute leukaemia, human immunodeficiency virus, other primary or secondary immunodeficiency)
- Medically immunosuppressed (e.g. following solid organ transplant; current or recent (<6 months) cytotoxic chemotherapy or radiotherapy; current or recent (<3 months) high-dose glucocorticoids; haematopoietic stem cell transplant)
- Pregnant (any stage)
- Infants: newborn whose mother has had chickenpox as above; premature infants <28 weeks

#### Choice of prophylaxis\*

- Immunocompromised adults: acyclovir 800 mg four times a day orally or valaciclovir 1 g three times daily orally, started 7 days after exposure or 7 days after first day of rash in person exposed to. Consider varicella zoster immune globulin (VZIG) only if renal impairment or malabsorption.
- Pregnant women (first 20 weeks): VZIG 1 g by slow intramuscular injection
- Pregnant women (after 20 weeks): VZIG (same dose as first 20 weeks) or aciclovir. Valaciclovir as alternative, all antiviral doses as above.
- Neonate VZIG, dose adjusted

\*Based on revised UK 2019 Public Health England Guidelines. [https://assets.publishing.service.gov.uk/government/uploads/system/uploads/attachment\\_data/file/811544/VZIG\\_issuing\\_guidance.pdf](https://assets.publishing.service.gov.uk/government/uploads/system/uploads/attachment_data/file/811544/VZIG_issuing_guidance.pdf).

## Mumps

Mumps is a systemic viral infection characterised by swelling of the parotid glands. Infection is endemic worldwide and peaks at 5–9 years of age. Vaccination has reduced the incidence in children but incomplete coverage and waning immunity with time have led to outbreaks in young adults. Infection is spread by respiratory droplets.

### Clinical features

The median incubation period is 19 days, with a range of 15–24 days. Classical tender parotid enlargement, which is bilateral in 75%, follows a prodrome of pyrexia and headache (Fig. 13.12). Meningitis complicates up to 10% of cases. The cerebrospinal fluid (CSF) reveals a lymphocytic pleocytosis or, less commonly, neutrophils. Rare complications include encephalitis, transient hearing loss, labyrinthitis, electrocardiographic abnormalities, pancreatitis and arthritis.

Approximately 25% of post-pubertal males with mumps develop epididymo-orchitis but, although testicular atrophy occurs, sterility is unlikely. Oophoritis is less common. Abortion may occur if infection takes place in the first trimester of pregnancy. Complications may occur in the absence of parotitis.

### Diagnosis

The diagnosis is usually clinical. In atypical presentations without parotitis, serology for mumps-specific IgM or IgG seroconversion (fourfold rise in IgG convalescent titre) confirms the diagnosis. Virus can also be cultured from urine in the first week of infection or detected by PCR in urine, saliva or CSF.

Fig. 13.12 Typical unilateral mumps. **A** Note the loss of angle of the jaw on the affected (right) side. **B** Comparison showing normal (left) side.

### Management and prevention

Treatment is with analgesia. There is no evidence that glucocorticoids are of value for orchitis. Mumps vaccine is one of the components of the combined MMR vaccine.

## Influenza

Influenza is an acute systemic viral infection that primarily affects the respiratory tract and carries a significant mortality. It is caused by influenza A virus or, in milder form, influenza B virus. Infection is seasonal, and variation in the haemagglutinin (H) and neuraminidase (N) glycoproteins on the surface of the virus leads to disease of variable intensity each year. Minor changes in haemagglutinin are known as 'genetic drift', whereas a switch in the haemagglutinin or neuraminidase antigen is termed 'genetic shift'. Nomenclature of influenza strains is based on these glycoproteins, e.g. H1N1, H3N2 etc. Genetic shift results in the circulation of a new influenza strain within a community to which few people are immune, potentially initiating an influenza epidemic or pandemic in which there is a high attack rate and there may be increased disease severity. Re-assortment of swine, avian and human influenza strains can occur in pigs and lead to outbreaks of swine 'flu' in humans, as occurred in 2009, with the outbreak of H1N1pdm2009 influenza.

### Clinical features

After an incubation period of 1–3 days, uncomplicated disease leads to fever, malaise and cough. Viral pneumonia may occur, although pulmonary complications are most often due to superinfection with *Strep. pneumoniae*, *Staph. aureus* or other bacteria. Rare extrapulmonary manifestations include myositis, myocarditis, pericarditis and neurological complications (Reye syndrome in children, encephalitis or transverse myelitis). Mortality is greatest in older people, those with medical comorbidities and pregnant women. Polymorphisms in the gene encoding an antiviral protein, interferon-induced transmembrane protein 3 (IFITM3), are associated with more severe influenza.

### Diagnosis

Acute infection is diagnosed by viral antigen or RNA detection in a nasopharyngeal sample. The disease may also be diagnosed retrospectively by serology.

### Management and prevention

Management involves early microbiological identification of cases and good infection control, with an emphasis on hand hygiene and preventing dissemination of infection by coughing and sneezing. Administration of a neuraminidase inhibitor, e.g. oral oseltamivir, inhaled zanamivir, intravenous peramivir or the oral cap-dependent endonuclease inhibitor

baloxavir, can reduce the severity of symptoms if started within 48 hours of symptom onset (or possibly later in immunocompromised individuals). Antiviral drugs can also be used as prophylaxis in high-risk individuals during the 'flu' season. Resistance can emerge to neuraminidase inhibitors and so updated local advice should be followed with regard to the sensitivity to antivirals of the circulating strain.

Prevention relies on seasonal vaccination of older age groups, children 2–7 years of age and individuals with chronic medical illnesses that place them at increased risk of the complications of influenza, such as chronic cardiopulmonary diseases or immune compromise, as well as their health-care workers. The vaccine composition changes each year to cover the 'predicted' seasonal strains but vaccination may fail when a new pandemic strain emerges.

### Avian influenza

Avian influenza is caused by transmission of avian influenza A viruses to humans. Avian viruses, such as H5N1, possess alternative haemagglutinin antigens to seasonal influenza strains. Most cases have had contact with sick poultry, predominantly in South-east Asia, and person-to-person spread has been limited to date. Infections with H5N1 viruses have been severe, with enteric features and respiratory failure. Treatment depends on the resistance pattern but often involves oseltamivir. Vaccination against seasonal 'flu' does not adequately protect against avian influenza. There is a concern that adaptation of an avian strain to allow effective person-to-person transmission is likely to lead to a global pandemic of life-threatening influenza.

## Infectious mononucleosis and Epstein–Barr virus

Infectious mononucleosis (IM) is a clinical syndrome characterised by pharyngitis, cervical lymphadenopathy, fever and lymphocytosis (known colloquially as glandular fever). It is most often caused by Epstein–Barr virus (EBV) but other infections can produce a similar clinical syndrome (Box 13.30).

EBV is a gamma herpesvirus. In lower- or middle-income countries (LMIC), subclinical infection in childhood is virtually universal. In high income countries, primary infection may be delayed until adolescence or early adult life. Under these circumstances, about 50% of infections result in typical IM. The virus is usually acquired from asymptomatic excretors via saliva, either by droplet infection or environmental contamination in childhood, or by kissing among adolescents and adults. EBV is not highly contagious and isolation of cases is unnecessary.

### Clinical features

EBV infection has a prolonged but undetermined incubation period, followed in some cases by a prodrome of fever, headache and malaise. This is followed by IM with severe pharyngitis, which may include tonsillar exudates and non-tender anterior and posterior cervical lymphadenopathy. Palatal petechiae, periorbital oedema, splenomegaly, inguinal or axillary lymphadenopathy and macular, petechial or erythema multiforme rashes may occur. In most cases, fever resolves over 2 weeks, and fatigue and other abnormalities settle over a further few weeks. Complications are listed in Box 13.31. Death is rare but can occur due to respiratory obstruction, haemorrhage from splenic rupture, thrombocytopenia or encephalitis.

The diagnosis of EBV infection outside the usual age in adolescence and young adulthood is more challenging. In children under 10 years the illness is mild and short-lived, but in adults over 30 years of age it can be severe and prolonged. In both groups, pharyngeal symptoms are often absent. EBV may present with jaundice, as a PUO or with a complication.

### Long-term complications of EBV infection

Lymphoma complicates EBV infection in immunocompromised hosts (e.g. post-transplant lymphoproliferative disorder), and some forms of Hodgkin lymphoma are EBV-associated. The endemic form of Burkitt lymphoma complicates EBV infection in areas of sub-Saharan Africa

### 13.30 Causes of infectious mononucleosis syndrome

- Epstein–Barr virus infection
- Cytomegalovirus
- HHV-6 or 7
- HIV-1 primary infection
- Toxoplasmosis

(HHV = human herpes virus; HIV = human immunodeficiency virus)

### 13.31 Complications of Epstein–Barr virus infection

#### Common

- Severe pharyngeal oedema
- Antibiotic-induced rash (80%–90% with ampicillin)
- Hepatitis (80%)
- Prolonged post-viral fatigue (10%)
- Jaundice (<10%)

#### Uncommon

##### Neurological

- Cranial nerve palsies
- Polyneuritis
- Transverse myelitis
- Meningoencephalitis

##### Haematological

- Haemolytic anaemia
- Thrombocytopenia

##### Renal

- Abnormalities on urinalysis
- Interstitial nephritis

##### Cardiac

- Myocarditis
- ECG abnormalities
- Pericarditis

#### Rare

- Ruptured spleen
- Respiratory obstruction
- Agranulocytosis
- X-linked lymphoproliferative syndrome

#### EBV-associated malignancy

- Nasopharyngeal carcinoma
- Burkitt lymphoma
- Hodgkin lymphoma (certain subtypes only)
- Primary CNS lymphoma
- Lymphoproliferative disease in immunocompromised

where *falciparum* malaria is endemic. Nasopharyngeal carcinoma is a geographically restricted tumour seen in China and Alaska that is associated with EBV infection. X-linked lymphoproliferative (Duncan) syndrome is a familial lymphoproliferative disorder that follows primary EBV infection in boys without any other history of immunodeficiency; it is due to mutation of the *SAP* gene, causing failure of T-cell and NK-cell activation and inability to contain EBV infection.

### Investigations

Atypical lymphocytes are common in EBV infection but also occur in other causes of IM, acute retroviral syndrome with HIV infection, viral hepatitis, mumps and rubella (Fig. 13.13A). They are also a feature of dengue, malaria and other geographically restricted infections (see Box 13.18). A 'heterophile' antibody is present during the acute illness and convalescence, which is detected by the Paul–Bunnell or 'Monospot' test. A heterophile antibody is an antibody that has affinity for antigens other than the specific one, in this case animal immunoglobulins; the Paul–Bunnell and Monospot tests exploit this feature by detecting the ability of test serum to agglutinate sheep and horse red blood cells, respectively. Sometimes antibody production is delayed, so an initially negative test should be repeated. However, many children and 10% of adolescents with IM do not produce heterophile antibody at any stage.

Specific EBV serology confirms the diagnosis. Acute infection is characterised by IgM antibodies against the viral capsid, antibodies to EBV early antigen and the initial absence of antibodies to EBV nuclear antigen (anti-EBNA). Seroconversion of anti-EBNA at approximately 1 month after the initial illness may confirm the diagnosis in retrospect. CNS infections may be diagnosed by detection of viral DNA in CSF.

**Fig. 13.13** Features of infectious mononucleosis. **A** Atypical lymphocytes in peripheral blood. **B** Skin reaction to ampicillin.

### Management

Treatment is symptomatic. If a throat culture yields a  $\beta$ -haemolytic streptococcus, penicillin should be given. Administration of ampicillin or amoxicillin in this condition commonly causes an itchy macular rash and should be avoided (Fig. 13.13B). When pharyngeal oedema is severe, a short course of glucocorticoids, e.g. prednisolone 30 mg daily for 5 days, may help. Current antiviral drugs are not active against EBV.

Return to work or school is governed by physical fitness rather than laboratory tests; contact sports should be avoided until splenomegaly has resolved because of the danger of splenic rupture. Unfortunately, about 10% of patients with IM suffer a chronic relapsing syndrome.

### Cytomegalovirus

Cytomegalovirus (CMV), like EBV, circulates readily among children. A second period of virus acquisition occurs among adolescents and young adults, peaking between the ages of 25 and 35 years, rather later than with EBV infection. CMV infection is persistent, and is characterised by subclinical cycles of active virus replication and by persistent low-level virus shedding. Most post-childhood infections are therefore acquired from asymptomatic excretors who shed virus in saliva, urine, semen and genital secretions. Sexual transmission and oral spread are common among adults but infection may also be acquired through caring for children with asymptomatic infections.

#### Clinical features

Most post-childhood CMV infections are subclinical, although some young adults develop an IM-like syndrome and some have a prolonged influenza-like illness lasting 2 weeks or more. Physical signs resemble IM but in CMV infections hepatomegaly is more common, while lymphadenopathy, splenomegaly, pharyngitis and tonsillitis occur less often. Jaundice is uncommon and usually mild. Complications include meningoencephalitis, Guillain-Barré syndrome, autoimmune haemolytic anaemia, thrombocytopenia, myocarditis and skin eruptions, such as ampicillin-induced rash. Immunocompromised patients can develop hepatitis, oesophagitis, colitis, pneumonitis, retinitis, encephalitis and polyradiculitis.

Women who develop a primary CMV infection during pregnancy have about a 40% chance of passing CMV to the fetus, causing congenital infection and disease at any stage of gestation. Features include petechial rashes, hepatosplenomegaly and jaundice; 10% of infected infants will have long-term CNS sequelae, such as microcephaly, cerebral calcifications, chorioretinitis and deafness. Infections in the newborn usually are asymptomatic or have features of an IM-like illness, although subtle sequelae affecting hearing or mental development may occur.

#### Investigations

Atypical lymphocytosis is not as prominent as in EBV infection and heterophile antibody tests are usually negative. LFTs are often abnormal, with

an alkaline phosphatase level raised out of proportion to transaminases. Serological diagnosis depends on the detection of CMV-specific IgM antibody plus a fourfold rise or seroconversion of IgG. In the immunocompromised, antibody detection is unreliable and detection of CMV in an involved organ by PCR, antigen detection, culture or histopathology establishes the diagnosis. Detection of CMV in the blood may be useful in transplant populations but not in HIV-positive individuals, since in HIV infection CMV reactivates at regular intervals, but these episodes do not correlate well with episodes of clinical disease. Detection of CMV in urine is not helpful in diagnosing infection, except in neonates, since CMV is intermittently shed in the urine throughout life following infection.

#### Management

Only symptomatic treatment is required in the immunocompetent patient. Immunocompromised individuals are treated with intravenous ganciclovir 5 mg/kg twice daily or with oral valganciclovir 900 mg twice daily for at least 14 days. Foscarnet or cidofovir is also used in CMV treatment of immunocompromised patients who are resistant to or intolerant of ganciclovir-based therapy. They can be given intravitreally if required. Maribavir is an investigational agent also being studied for resistant strains of CMV. Letermovir is a newer antiviral used in the prevention of CMV in high-risk transplant patients, e.g. some haematopoietic stem cell transplant recipients.

### Dengue

Dengue is a febrile illness caused by a flavivirus transmitted by mosquitoes. It is endemic in Asia, the Pacific, Africa and the Americas (Fig. 13.14). Approximately 400 million infections and 100 million clinically apparent infections occur annually, and dengue is the most rapidly spreading mosquito-borne viral illness. The principal vector is the mosquito *Aedes aegypti*, which breeds in standing water; collections of water in containers, water-based air coolers and tyre dumps are a good environment for the vector in large cities. *Aedes albopictus* is a vector in some South-east Asian countries. There are four serotypes of dengue virus, all producing a similar clinical syndrome; type-specific immunity is life-long but immunity against the other serotypes lasts only a few months. Dengue haemorrhagic fever (DHF) and dengue shock syndrome (DSS) occur in individuals immune to one dengue virus serotype who are subsequently infected with a different serotype. Prior immunity results in increased uptake of virus by cells expressing the antibody Fc receptor and increased T-cell activation with resultant cytokine release, causing capillary leak and disseminated intravascular coagulation (DIC; Ch. 25). Previously, dengue was seen in small children and DHF/DSS in children 2–15 years old, but these conditions are now being seen in children less than 2 years old, and most frequently in those 16–45 years of age or older, in whom severe organ dysfunction is more common. Other epidemiological changes include the spread of dengue into rural communities and greater case fatality in women.

<b>Convalescence</b>	<ul style="list-style-type: none"> <li>• Slow and may be associated with prolonged fatigue syndrome, arthralgia or depression</li> </ul>
<b>Complications</b>	<ul style="list-style-type: none"> <li>• Dengue haemorrhagic fever and disseminated intravascular coagulation</li> <li>• Dengue shock syndrome</li> <li>• Severe organ involvement</li> <li>• Vertical transmission if infection within 5 weeks of delivery</li> </ul>

### Clinical features

Many cases of dengue infection are asymptomatic in children. Clinical disease presents with undifferentiated fever termed 'dengue-like illness'. When dengue infection occurs with characteristic symptoms or signs it is termed 'dengue' (Box 13.32). A rash frequently follows the initial febrile phase as the fever settles. Laboratory features include leucopenia, neutropenia, thrombocytopenia and elevated alanine aminotransferase (ALT) or aspartate aminotransferase (AST). The differential diagnosis of thrombocytopenia with fever in dengue endemic areas is shown in Box 13.33. Many symptomatic infections run an uncomplicated course but complications or a protracted convalescence may ensue. Warning signs justify intense medical management and monitoring for progression to severe dengue. Atypical clinical features of dengue are increasingly common, especially in infants or older patients, and in rural locations (Box 13.34). These, along with DHF or DSS, are recognised as features of severe dengue in the 2015 case definition and contribute to mortality, mandating urgent medical management.

The period 3–7 days after onset of fever is termed the 'critical' phase, during which signs of DHF or DSS may develop. In mild forms, petechiae occur in the arm when a blood pressure cuff is inflated to a point between systolic and diastolic blood pressure and left for 5 minutes (the positive 'tourniquet test') – a non-specific test of capillary fragility and thrombocytopenia. As the extent of capillary leak increases, DSS develops, with

13.33 Differential diagnosis of thrombocytopenia with fever in dengue endemic areas

<p>(ALT = alanine aminotransferase; AST = aspartate aminotransferase; CNS = central nervous system; WHO = World Health Organization) Adapted from <a href="https://www.cdc.gov/nndss/conditions/dengue-virus-infections/case-definition/2015/">https://www.cdc.gov/nndss/conditions/dengue-virus-infections/case-definition/2015/</a>.</p>	

a raised haematocrit, tachycardia and hypotension, pleural effusions and ascites. This may progress to metabolic acidosis and multi-organ failure, including acute respiratory distress syndrome (ARDS). Minor (petechiae, ecchymoses, epistaxis) or major (gastrointestinal or vaginal) haemorrhage, a feature of DHF, may occur. Cerebrovascular bleeding may be a complication of severe dengue.

### Diagnosis

In endemic areas, mild dengue must be distinguished from other viral infections. The diagnosis can be confirmed by seroconversion of IgM or a fourfold rise in IgG antibody titres. Serological tests may detect cross-reacting antibodies from infection or vaccination against other flaviviruses, including yellow fever virus, Japanese encephalitis virus and West Nile

virus. Isolation of dengue virus or detection of dengue virus RNA by PCR in blood or CSF is available in specialist laboratories. Commercial enzyme-linked immunosorbent assay (ELISA) kits to detect the NS1 viral antigen, although less sensitive than PCR, are available in many endemic areas.

### Management and prevention

Treatment is supportive, emphasising fluid replacement and appropriate management of shock and organ dysfunction, which is a major determinant of morbidity and mortality. With intensive care support, mortality rates are 1% or less. Aspirin should be avoided due to bleeding risk. Glucocorticoids have not been shown to help. No existing antivirals are effective.

Breeding places of *Aedes* mosquitoes should be eliminated and the adults destroyed by insecticides. A live attenuated tetravalent chimeric vaccine was licensed in 2019 for children. It is recommended only for children who have already had a first infection and live in a dengue endemic area. Other vaccines are also in development.

## Yellow fever

Yellow fever is a haemorrhagic fever of the tropics, caused by a flavivirus. It is a zoonosis of monkeys in West and Central African, and South and Central American tropical rainforests, and may cause epidemics (see Fig. 13.14). Transmission is by tree-top mosquitoes, *Aedes africanus* (Africa) and *Haemagogus* spp. (America). The infection is introduced to humans either by infected mosquitoes when trees are felled, or by monkeys raiding human settlements. In towns, yellow fever may be transmitted between humans by *Aedes aegypti*, which breeds efficiently in small collections of water. The distribution of this mosquito is far wider than that of yellow fever, threatening geographical spread.

Yellow fever causes up to 170 000 infections each year, mainly in sub-Saharan Africa. Mortality varies but is approximately 15%. Humans are infectious during the viraemic phase, which starts 3–6 days after the bite of the infected mosquito and lasts for 4–5 days.

### Clinical features

After an incubation period of 3–6 days, yellow fever is often a mild febrile illness lasting less than 1 week, with headache, myalgia, conjunctival erythema and bradycardia. This is followed by fever resolution (defervescence) but, in some cases, fever recurs after a few hours to days. In more severe disease, fever recrudescence is associated with lower back pain, abdominal pain and somnolence, prominent nausea and vomiting, bradycardia and jaundice. Liver damage and DIC lead to bleeding with petechiae, mucosal haemorrhages and gastrointestinal bleeding. Shock, hepatic failure, renal failure, seizures and coma may ensue.

### Diagnosis

The differential diagnosis includes malaria, typhoid, viral hepatitis, leptospirosis, haemorrhagic fevers and aflatoxin poisoning. Diagnosis of yellow fever can be confirmed by detection of virus in the blood in the first 3–4 days of illness by culture or reverse transcription polymerase chain reaction (RT-PCR), by the presence of IgM or by a fourfold rise in IgG antibody titre. Leucopenia is characteristic. Liver biopsy should be avoided due to the risk of fatal bleeding. Postmortem features, such as acute mid-zonal necrosis and Councilman bodies with minimal inflammation in the liver, are suggestive but not specific. Immunohistochemistry for viral antigens improves specificity.

### Management and prevention

Treatment is supportive, with meticulous attention to fluid and electrolyte balance, urine output and blood pressure. Blood transfusions, plasma expanders and peritoneal dialysis may be necessary. Patients should be isolated, as their blood and body products may contain virus particles.

A single vaccination with a live attenuated vaccine gives full protection and travellers do not require a booster unless specified by

individual countries' travel requirements. Potential side-effects include hypersensitivity, acute neurotropic disease (encephalitis) (YEL-NVD) and systemic features of yellow fever with acute viscerotropic disease (YEL-AVD) caused by the attenuated virus. Vaccination is not recommended in people who are significantly immunosuppressed or aged over 60 years. The risk of vaccine side-effects must be balanced against the risk of infection for less immunocompromised hosts, pregnant women and older patients. An internationally recognised certificate of vaccination is sometimes necessary when crossing borders. The Eliminate Yellow Fever Epidemics strategy was launched in 2017 and aims to protect a billion people living in at-risk countries in Africa and the Americas by 2026.

## Viral haemorrhagic fevers

Viral haemorrhagic fevers (VHFs) are zoonoses caused by several different viruses (Box 13.35). They are geographically restricted and previously occurred in rural settings or in health-care facilities. The largest outbreak of VHF to date started in 2014, with Ebola circulating in Guinea, Liberia and Sierra Leone. The outbreak resulted in more than 28 000 cases by 2016. Since 2018–19 there has been an ongoing Ebola outbreak in the eastern part of the Democratic Republic of Congo (DRC).

Serological surveys have shown that Lassa fever is widespread in West Africa and may lead to up to 500 000 infections annually. Mortality overall may be low, as 80% of cases are asymptomatic, but in hospitalised cases mortality averages 15%. Marburg has been documented less frequently, with outbreaks in the DRC and Uganda, but the largest outbreak to date involved 163 cases in Angola in 2005. Mortality rates of Ebola and Marburg vary but are high.

VHFs have extended into Europe, with an outbreak of Congo–Crimean haemorrhagic fever (CCHF) in Turkey in 2006, and cases of haemorrhagic fever with renal syndrome in the Balkans and Russia. An outbreak of CCHF in 2011 in Gujarat, India, involved several health-care workers and emphasised the importance of maintaining a high index of suspicion for VHF and implementing appropriate infection control measures at the first opportunity. Kyasanur forest disease is a tick-borne VHF currently confined to a small focus in Karnataka, India; there are about 500 cases annually. Monkeys are the principal hosts but, with forest felling, there are fears that this disease will increase. Severe fever with thrombocytopenia syndrome (SFTS) is a tick-borne VHF that has emerged in rural China, South Korea and Japan since 2009.

New outbreaks and new agents are identified sporadically. Details on recent disease outbreaks can be found at the WHO website (see 'Further information').

### Clinical features

VHFs present with non-specific fever, malaise, body pains, sore throat and headache. On examination, conjunctivitis, throat injection, an erythematous or petechial rash, haemorrhage, lymphadenopathy and bradycardia may be noted. Endothelial dysfunction causes capillary leak. Bleeding is due to endothelial damage and platelet dysfunction. Hypovolaemic shock and ARDS may develop.

Haemorrhage is a late feature of most VHFs and many patients present with earlier features. In Lassa fever, joint and abdominal pain is prominent. A macular blanching rash may be present but bleeding is unusual, occurring in only 20% of hospitalised patients. Encephalopathy may develop and deafness affects 30% of survivors. In CCHF, bleeding, manifest by haematemesis or bleeding per rectum, may be an early feature, accompanied by derangement of LFTs.

The clue to the viral aetiology comes from the travel and exposure history. Travel to an outbreak area, activity in a rural environment and contact with sick individuals or animals within 21 days all increase the risk of VHF. Enquiry should be made about insect bites, hospital visits and attendance at ritual funerals (Ebola virus infection). For Lassa fever, retrosternal pain, pharyngitis and proteinuria have a positive predictive value of 80% in West Africa.

13.35 Viral haemorrhagic fevers						
Disease	Reservoir	Transmission	Incubation period	Geography	Mortality rate	Clinical features of severe disease <sup>1</sup>
<b>Lassa fever</b>	Multimammate rats ( <i>Mastomys natalensis</i> )	Urine from rat Body fluids from patients	6–21 days	West Africa	15%	Haemorrhage, shock, encephalopathy, ARDS (responds to ribavirin), deafness in survivors
<b>Ebola fever</b>	Fruit bats (Pteropodidae family) and bush meat	Body fluids from patients Handling infected primates	2–21 days	Central Africa Outbreaks as far north as Sudan	25%–90%	Haemorrhage and/or diarrhoea, hepatic failure and acute kidney injury
<b>Marburg fever</b>	Undefined	Body fluids from patients Handling infected primates	3–9 days	Central Africa Outbreak in Angola	25%–90%	Haemorrhage, diarrhoea, encephalopathy, orchitis
<b>Yellow fever</b>	Monkeys	Mosquitoes	3–6 days	See Fig. 13.14	~15%	Hepatic failure, acute kidney injury, haemorrhage
<b>Dengue</b>	Humans	<i>Aedes aegypti</i>	2–7 days	See Fig. 13.14	<10% <sup>2</sup>	Haemorrhage, shock
<b>Crimean–Congo haemorrhagic fever</b>	Small vertebrates	<i>Ixodes</i> tick	1–3 days up to 9 days	Africa, Asia, Eastern Europe	30%	Encephalopathy, early haemorrhage, hepatic failure, acute kidney injury, ARDS
	Domestic and wild animals	Body fluids	3–6 days up to 13 days			
<b>Rift Valley fever</b>	Domestic livestock	Contact with animals, mosquito or other insect bites	2–6 days	Africa, Arabian peninsula	1%	Haemorrhage, blindness, meningoencephalitis (complications only in a minority)
<b>Kyasanur fever</b>	Monkeys	Ticks	3–8 days	Karnataka State, India	5%–10%	Haemorrhage, pulmonary oedema, neurological features, iridokeratitis in survivors
<b>Bolivian and Argentinian haemorrhagic fever (Junin and Machupo viruses)</b>	Rodents ( <i>Calomys</i> spp.)	Urine, aerosols Body fluids from case (rare)	5–19 days (3–6 days for parenteral)	South America	15%–30%	Haemorrhage, shock, cerebellar signs (may respond to ribavirin)
<b>Haemorrhagic fever with renal syndrome (Hantaan fever)</b>	Rodents	Aerosols from faeces	5–42 days (typically 14 days)	Northern Asia, northern Europe, Balkans	5%	Acute kidney injury, cerebrovascular accidents, pulmonary oedema, shock (hepatic failure and haemorrhagic features only in some variants)
<b>Severe fever with thrombocytopenia syndrome (SFTS)</b>	Domestic and wild animals	<i>Ixodes</i> ticks	5–14 days, average 9 days	China, South Korea, Japan	7%	Organ failure (liver, heart, kidney, lungs), haemorrhage and disseminated intravascular coagulopathy, neuropsychiatric, prominent thrombocytopenia

<sup>1</sup>All potentially have circulatory failure. <sup>2</sup>Mortality of uncomplicated and haemorrhagic dengue fever, respectively. (ARDS = acute respiratory distress syndrome)

### Investigations and management

Non-specific findings include leucopenia, thrombocytopenia and proteinuria. In Lassa fever, an AST of >150 U/L is associated with a 50% mortality. It is important to exclude other causes of fever, especially malaria, typhoid and respiratory tract infections. In the UK, most patients suspected of having a VHF turn out to have malaria.

A febrile patient from an endemic area within the 21-day incubation period, who has specific epidemiological risk factors (see Fig. 13.7) or signs of organ failure or haemorrhage, should be treated as being at high risk of VHF; appropriate infection control measures must be implemented and the patient transferred to a centre with biosafety level (BSL) 4 facilities if they test positive. Individuals with a history of travel within 21 days and fever, but without the relevant high-risk epidemiological

features or signs of VHF, are classified as medium-risk and should have an initial blood sample tested to exclude malaria. If this is negative, relevant specimens (blood, throat swab, urine and pleural fluid, if available) are collected and sent to an appropriate reference laboratory for nucleic acid detection (PCR), virus isolation and serology. If patients are still felt to be at significant risk of VHF or if infection is confirmed, they should be transferred to a specialised HCID unit. All further laboratory tests should be performed at BSL 4. Transport requires an ambulance with BSL 3 facilities.

In addition to general supportive measures, ribavirin is given intravenously (100 mg/kg, then 25 mg/kg daily for 3 days and 12.5 mg/kg daily for 4 days) when Lassa fever or South American haemorrhagic fevers are suspected.

### Prevention

Ribavirin has been used as prophylaxis in close contacts in Lassa fever but there are no formal trials of its efficacy.

### Ebola virus disease (EVD)

Ebola virus disease (EVD) is thought to spread to human populations from fruit bats, sometimes indirectly via contact with infected primates or other animals. Person-to-person spread, via contact with blood, secretions or body parts, establishes EVD in populations. Family members, health-care workers and people performing traditional burials are at particular risk. The 2014 outbreak involved the Zaire strain of Ebola virus.

### Clinical features

The incubation period is 2–21 days but typically 8–10 days. Fever and non-specific signs are accompanied by abdominal pain, diarrhoea, vomiting and hiccups. A maculopapular rash occurs after 5–7 days in some. Although bleeding from the gums or venepuncture sites or in the stool occurs, haemorrhage may be less prominent than in other VHFs and is often a terminal event. In contrast, fluid losses from diarrhoea are more marked and reach 10L per day. Complications include meningoencephalitis, uveitis and miscarriages in pregnant women.

### Investigations

Lymphopenia occurs, followed by neutrophilia, atypical lymphocytosis, thrombocytopenia and coagulation abnormalities. Elevations of AST/ALT, features of acute kidney injury, electrolyte disturbances and proteinuria are also observed. The virus is detected by a PCR in blood or body fluids, but may need retesting if the duration of symptoms is less than 3 days. Antigen detection has also been used in rural settings. Serology provides a retrospective diagnosis.

### Management

Treatment is supportive and aimed at fluid replacement. Bacterial super-infections should be promptly treated. Mortality varies but is approximately 50% (range 25%–90%). Survivors recover from the second week of illness but experience late sequelae, including arthritis (76%), uveitis (60%) and deafness (24%), while skin sloughing is common. Relapse with meningitis is reported months after recovery. Monoclonal antibodies are a promising therapeutic approach.

### Prevention

Ebola virus may be detected in the semen months after recovery. Male survivors are therefore encouraged to practise safe sex for 12 months after symptom onset or until two negative semen tests, but recommendations vary. Public health measures are essential for outbreak control and involve contact surveillance and monitoring through the incubation period, separating healthy from sick individuals, practising safe burial methods and ensuring appropriate infection control measures to protect health-care and laboratory workers, including provision of personal protective equipment such as gloves, gowns and full-face protection (face shield or masks combined with goggles). An Ebola glycoprotein vaccine, rVZV-ZEBOV, was shown to be effective in 2016 after a trial in West Africa and has been used in DRC as well as another viral vector vaccine, Ad26.ZEBOV/MVA-BN-Filo.

## Zika virus

Zika virus is a flavivirus spread from primate hosts by *Aedes aegypti* and *Aedes albopictus*, which bite during the day. Described in Africa and Asia since 2015, it has been epidemic in the Americas, where a mosquito–man–mosquito transmission cycle is established. It also can be transmitted in semen.

### Clinical features

The incubation period is 3–12 days. Infection is asymptomatic or mild, resembling dengue with fever, arthralgia, conjunctivitis and maculopapular

rash. Complications include increased reports of Guillain–Barré syndrome. Zika-related complications occur in 5%–15% of pregnant women with infection. The major concern has been a marked increase in microcephaly in pregnant women infected with Zika virus, as well as increased rates of cerebral calcification, deafness, visual problems such as chorioretinal scarring, joint contractures (arthrogryposis), hydrops fetalis and growth retardation.

### Investigations

Routine blood tests are usually normal but may show leucopenia, thrombocytopenia or increased transaminases. PCR detects virus in the first week of illness or in urine up to 14 days. Serology provides a retrospective diagnosis but cross-reacts with other flaviviruses. Plaque-reduction neutralisation testing can be used to detect virus-specific neutralising antibodies and distinguish between cross-reacting antibodies in primary flavivirus infections.

### Prevention

Prevention focuses on avoiding mosquito bites. Since Zika virus may be found in the semen or genital secretions for prolonged periods, infected individuals should practise safe sex for at least 6 months and planned pregnancy should be postponed for at least 6 months. WHO guidance recommends individuals who have travelled to an endemic area but are asymptomatic should practise safe sex for 6 months in men and 2 months in women, but updated guidance should be sought. There is currently no vaccine.

## Viral infections of the skin

### Herpes simplex virus 1 and 2

Herpes simplex viruses (HSVs) cause recurrent mucocutaneous infection; HSV-1 typically involves the mucocutaneous surfaces of the head and neck (Fig. 13.15), while HSV-2 predominantly involves the genital mucosa (see p. 380), although there is overlap (see Box 13.27). The seroprevalence of HSV-1 is 30%–100%, varying by socioeconomic status, while that of HSV-2 is 20%–60%. Infection is acquired by inoculation of viruses shed by an infected individual on to a mucosal surface in a susceptible person. The virus infects sensory and autonomic neurons and establishes latent infection in the nerve ganglia. Primary infection is followed by life-long episodes of reactivation.

### Clinical features

Primary HSV-1 or 2 infection is more likely to be symptomatic later in life, causing gingivostomatitis, pharyngitis or painful genital tract lesions. The primary attack may be associated with fever and regional lymphadenopathy.

### Recurrence

Recurrent attacks occur, most often in association with concomitant medical illness, menstruation, mechanical trauma, immunosuppression, psychological stress or, for oral lesions, ultraviolet light exposure. HSV reactivation in the oral mucosa produces the classical ‘cold sore’ or ‘herpes labialis’. Prodromal hyperaesthesia is followed by rapid vesiculation, pustulation and crusting. Recurrent HSV genital disease is a common cause of recurrent painful ulceration. An inoculation lesion on the finger may cause a paronychia, termed a ‘whitlow’, in contacts of patients with herpetic lesions (Fig. 13.15B).

### Complications

Disseminated cutaneous lesions can occur in individuals with underlying dermatological diseases, such as eczema (eczema herpeticum) (Fig. 13.15C). Herpes keratitis presents with pain and blurring of vision; characteristic dendritic ulcers are visible on slit-lamp examination and may produce corneal scarring and permanent visual impairment.

**Fig. 13.15** Cutaneous manifestations of herpes simplex virus 1 (HSV-1). **A** Acute HSV-1. There were also vesicles in the mouth – herpetic stomatitis. **B** Herpetic whitlow. **C** Eczema herpeticum. HSV-1 infection spreads rapidly in eczematous skin.

Primary HSV-2 can cause meningitis or transverse myelitis. HSV is the leading cause of sporadic viral encephalitis; this follows either primary or secondary disease, usually with HSV-1. A haemorrhagic necrotising temporal lobe cerebritis produces temporal lobe epilepsy and altered consciousness/coma. Without treatment, mortality is 80%. HSV is also implicated in the pathogenesis of Bell's palsy with a lower motor neuron 7th nerve palsy, although antivirals have not been demonstrated to improve outcome.

Neonatal HSV disease is usually associated with primary infection of the mother at term (see [Box 13.24](#)). In excess of two-thirds of cases develop disseminated disease with cutaneous lesions, hepatitis, pneumonitis and, frequently, encephalitis.

Immunocompromised hosts can develop visceral disease with oesophagitis, hepatitis, pneumonitis, encephalitis or retinitis.

### Diagnosis

Differentiation from other vesicular eruptions is achieved by demonstration of virus in vesicular fluid, usually by direct immunofluorescence or PCR. HSV encephalitis is diagnosed by a positive PCR for HSV in CSF. Serology is of limited value.

### Management

Therapy of localised disease must commence in the first 48 hours of clinical disease (primary or recurrent); thereafter it is unlikely to influence clinical outcome. Oral lesions in an immunocompetent individual may be treated with topical aciclovir. All severe manifestations should be treated, regardless of the time of presentation (see [Box 13.28](#)). Suspicion of HSV encephalopathy requires immediate antiviral therapy. Aciclovir resistance is encountered occasionally in immunocompromised hosts, in which case foscarnet is recommended.

## Human herpesvirus 8

Human herpesvirus 8 (HHV-8) (see [Box 13.27](#)) causes Kaposi's sarcoma in both AIDS-related and endemic non-AIDS-related forms. HHV-8 is spread via saliva, and men who have sex with men have an increased incidence of infection. Seroprevalence varies widely, being highest in sub-Saharan Africa. HHV-8 also causes two rare haematological malignancies: primary effusion lymphoma and multicentric Castleman's disease. Kaposi's sarcoma inflammatory cytokine syndrome is an HHV-8-associated syndrome that mimics sepsis. Current antivirals are not effective and treatment is with rituximab plus chemotherapy.

## Enterovirus infections

### Hand, foot and mouth disease

This systemic infection is caused by enteroviruses (mainly coxsackievirus A16 and enterovirus 71) and echoviruses. It affects children and

occasionally adults, resulting in local or household outbreaks, particularly in the summer months, with recent epidemics in South-east Asia. A relatively mild illness with fever and lymphadenopathy develops after an incubation period of approximately 10 days; 2–3 days later, a painful papular or vesicular rash appears on palmoplantar surfaces of the hands and feet, with associated oral lesions on the buccal mucosa and tongue that ulcerate rapidly. A papular erythematous rash may appear on the buttocks and thighs. Enterovirus A71 and coxsackie A6 have been associated with more severe illness, including acute flaccid paralysis. Antiviral treatment is not available, and management consists of symptom relief with analgesics.

### Herpangina

This infection, mainly caused by coxsackieviruses, primarily affects children and adolescents in the summer months. It is characterised by a small number of vesicles at the soft/hard palate junction, often associated with high fever, an extremely sore throat and headache. The lesions are short-lived, rupturing after 2–3 days and rarely persisting for more than 1 week. Treatment is with analgesics if required. Culture of the virus from vesicles or DNA detection by PCR differentiates herpangina from HSV.

## Poxviruses

These DNA viruses are rare but potentially important pathogens.

### Smallpox (*variola*)

Smallpox, which has high mortality, was eradicated worldwide by a global vaccination programme but remains a potential bioweapon. The virus is spread by the respiratory route or contact with lesions, and is highly infectious.

The incubation period is 7–17 days. A prodrome with fever, headache and prostration leads, in 1–2 days, to the rash, which develops through macules and papules to vesicles and pustules, worst on the face and distal extremities. Lesions in one area are all at the same stage of development with no cropping (unlike chickenpox). Vaccination can lead to a modified course of disease with milder rash and lower mortality.

If a case of smallpox is suspected, national public health authorities must be contacted. Electron micrography (like [Fig. 13.16](#)) and DNA detection tests (PCR) are used to confirm diagnosis.

### Monkeypox

Despite the name, the animal reservoirs for this virus are small squirrels and rodents. It causes a rare zoonotic infection in communities in the rainforest belt of Central Africa, producing a vesicular rash that is indistinguishable from smallpox, but differentiated by the presence of lymphadenopathy. Little person-to-person transmission occurs. Outbreaks outside Africa have been linked to importation of African animals as exotic pets. Diagnosis is by electron micrography or DNA detection (PCR).

**Fig. 13.16** Electron micrograph of molluscum contagiosum, a poxvirus. Courtesy of Prof. Goura Kudesia, Northern General Hospital, Sheffield.

### Cowpox

Humans in contact with infected cows develop large vesicles, usually on the hands or arms and associated with fever and regional lymphadenitis. The reservoir is thought to be wild rodents.

### Vaccinia virus

This laboratory strain is used as the smallpox vaccine. Widespread vaccination is no longer recommended due to the likelihood of local spread from the vaccination site (potentially life-threatening in those with eczema (eczema vaccinatum) or immune deficiency) and of encephalitis. However, vaccination may still be recommended for key medical staff.

### Other poxviruses: orf and molluscum contagiosum

See page 1091 and [Figure 13.16](#).

## Gastrointestinal viral infections

### Norovirus

Norovirus is the most common UK cause of infectious gastroenteritis and causes outbreaks in hospital wards, cruise ships and military camps. Food handlers may transmit this virus, which is relatively resistant to decontamination procedures. The incubation period is 24–48 hours. High attack rates and prominent vomiting are characteristic. Diagnosis may be achieved by antigen or DNA detection (PCR) in stool samples, although the characteristic clinical and epidemiological features mean that microbiological confirmation is not always necessary. The virus is highly infectious and cases should be isolated and environmental surfaces cleaned with detergents and disinfected with bleach.

### Astrovirus

Astroviruses cause diarrhoea in small children and occasionally in immunocompromised adults.

### Rotavirus

Rotaviruses infect enterocytes and are a major cause of diarrhoeal illness in young children worldwide. Winter epidemics are common in high-income countries, particularly in nurseries. Adults in close contact with cases may develop disease. The incubation period is 48 hours and patients present with watery diarrhoea, vomiting, fever and abdominal pain. Dehydration is prominent. Diagnosis is aided by commercially available enzyme immunoassay kits, which require fresh or refrigerated

stool samples. Immunity develops to natural infection. Monovalent and multivalent vaccines have been licensed in many countries and have now demonstrated efficacy in large trials in Africa and the Americas.

## Hepatitis viruses (A–E)

See [Chapter 24](#).

### Other viruses

Adenoviruses are frequently identified from stool culture and implicated as a cause of diarrhoea in children. They have also been linked to cases of intussusception.

## Respiratory viral infections

These infections are described further on page 512.

Adenoviruses, rhinoviruses and enteroviruses (coxsackieviruses and echoviruses) often produce non-specific upper respiratory tract symptoms but may cause viral pneumonia. Parainfluenza and respiratory syncytial viruses cause upper respiratory tract disease, croup and bronchiolitis in small children and pneumonia in the immunocompromised. Respiratory syncytial virus also causes pneumonia in nursing home residents and may be associated with nosocomial pneumonia. Metapneumovirus and bocavirus cause upper and occasionally lower respiratory tract infection, especially in immunosuppressed individuals.

## Coronaviruses

Coronaviruses are single-strand positive-sense RNA viruses that cause widespread infection in animals and humans.

Coronaviruses HCoV-229E, HCoV-NL63, HCoV-KU1 and HCoV-OC43 have a worldwide distribution. They usually cause mild upper respiratory tract infection, but occasionally more serious respiratory infection at extremes of age or in immunocompromised hosts.

Three coronaviruses have emerged in recent years that cause more serious infections. These are SARS-CoV (severe acute respiratory syndrome coronavirus), MERS-CoV (Middle East respiratory syndrome coronavirus) and SARS-CoV-2 (the cause of coronavirus disease 2019; COVID-19). These coronaviruses have emerged as zoonoses from bats and potentially intermediate hosts. The intermediate hosts for SARS-CoV and MERS-CoV include palm civets and camels respectively, but the identity of the intermediate host(s) for SARS-CoV-2 remains elusive.

It has been suggested that both SARS-CoV and SARS-CoV-2 may have been spread to humans through contact with wild animals in wild food markets.

### Pathogenesis

The coronaviruses contain non-structural proteins including RNA-polymerases and proteases and structural proteins including the envelope, spike (S) glycoprotein and nucleocapsid protein. RNA replication occurs in double membrane vesicles originating from the endoplasmic reticulum and is incorporated into virions which are released from infected cells. The coronaviruses infect a range of cells, including respiratory and gastrointestinal epithelial cells. Initial interactions involve the S glycoprotein, which binds to the surface receptor. For SARS, SARS-CoV-2 and HCoV-NL63 the receptor is the human angiotensin-converting enzyme 2 (hACE2). Infection with SARS-CoV-2 results in reduced expression of hACE2, a protein that normally plays important anti-inflammatory roles in the lung, and it is thought that reduced expression may contribute to pathogenesis. In SARS-CoV-2 infection the S glycoprotein requires priming by the human serine protease TMPRSS2 to allow optimal engagement with its receptor, hACE2. For MERS-CoV the receptor is the dipeptidyl peptidase 4 (DPP4). The receptor-binding domain of the S glycoprotein undergoes mutation to allow adaptation during cross-species transmission from bats to other species, including man.

Coronaviruses induce suboptimal early interferon responses, in part thought to be because the RNA is shielded from pattern

recognition receptors, since it is contained in the double membrane vesicles. Furthermore, several coronaviruses contain a nucleocapsid protein that suppresses interferon production. However, despite suppression of interferon in some cells, other cells such as macrophages and dendritic cells do produce interferon, and excessive production of interferon and other pro-inflammatory cytokines by these cells is associated with failure to clear virus and poor outcomes. Antiviral immunity requires production of neutralising antibody and effective CD4<sup>+</sup> and CD8<sup>+</sup> T-cell responses. These same antiviral responses, however, also appear to cause tissue injury. In SARS-CoV and SARS-CoV-2 infection pulmonary complications typically emerge after 1–2 weeks and are thought to result from dysregulation of innate and adaptive immune responses. For SARS-CoV-2 it is suggested that suboptimal innate immune responses and recruitment of pro-inflammatory CCR2<sup>+</sup> monocytes contribute to inflammation, while apoptotic cell death of CD8<sup>+</sup> T-cells is prominent. Disease is more severe in older individuals and it is thought this may correlate with suboptimal T-cell responses and enhanced pro-inflammatory responses with ageing. Skewing of immune responses away from early protective interferon responses and suboptimal antiviral immunity may lead to dysregulated immune responses and prolonged inflammatory responses that lead to tissue injury in multiple organs. For SARS-CoV-2, activation of the clotting cascade in association with marked inflammation appears to be a distinct feature. Microthrombi occur around the body and both venous thromboembolism and arterial clots in the heart and brain may be prominent features.

### SARS coronavirus (SARS-CoV)

SARS-CoV emerged as a major respiratory pathogen during an outbreak of SARS in 2002–2003, in which there were approximately 8000 cases. The virus originated in Guangdong, China, and spread to several other countries, with secondary transmission reported in Canada (Toronto), Hong Kong, Taiwan, Singapore and Vietnam during the outbreak. SARS presented as a flu-like illness with non-specific symptoms, including fever, malaise, myalgia, headache, diarrhoea and shivering. In severe cases these progressed to pneumonia, requiring intensive care admission. The case fatality rate was approximately 11%.

According to the World Health Organization, SARS infection has been recorded only four times since the global epidemic, three times from laboratory accidents and once in southern China from an unknown source.

### Middle East respiratory syndrome coronavirus (MERS-CoV)

In 2012, a novel coronavirus, distantly related to SARS-CoV, caused several deaths connected with pneumonia in patients originating from the Middle East. The Middle East respiratory syndrome coronavirus (MERS-CoV) appears to be a zoonosis, involving transmission from bats to camels and then to humans. Over 20 countries have reported cases, although most cases have a history of travel to Saudi Arabia or other countries in the Arabian Peninsula. By 2020 there had been over 2500 reported cases. MERS-CoV remains an important but still geographically restricted coronavirus.

#### Clinical features

The incubation period in person-to-person transmission is 2–14 (average 5) days. Any age may be infected but the patients over 50 with medical comorbidities are particularly susceptible to severe disease. Initial symptoms are fever, chills, headache, myalgia, dry cough and dyspnoea. Abdominal pain and diarrhoea may be prominent. The mean period from symptom onset to hospitalisation is 4 days, and 5 days to intensive care unit admission. Illness is complicated by rapid development of respiratory failure and features of ARDS and multi-organ failure. Mortality is 35%.

#### Diagnosis and management

Laboratory features include lymphopenia, thrombocytopenia and raised lactate dehydrogenase (LDH). Diagnosis is confirmed by detection of virus RNA (PCR) in serum, nasopharyngeal or other respiratory samples. Antibody detection may also be useful. Treatment is supportive.

Strict infection control measures should be implemented for anyone with fever, severe respiratory illness and epidemiological risk factors. Patients should be managed in an airborne infection isolation room with contact and airborne infection control measures, including personal protective equipment for health-care workers.

### SARS-CoV-2

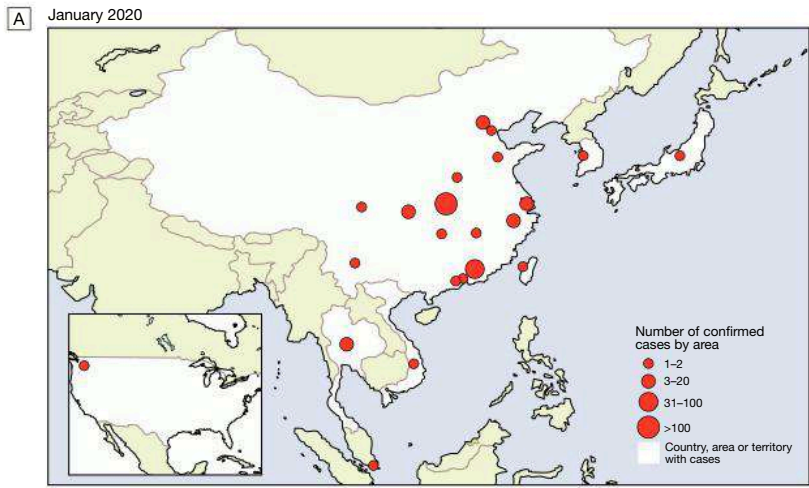

SARS-CoV-2 was first identified in December 2019 in Wuhan, China, where it caused an outbreak that spread rapidly to other parts of China and then the rest of the world. The virus is believed to have been transmitted to humans via horseshoe bats (*Rhinolophus sinicus*) and potentially other intermediate hosts, to whom individuals may have been exposed at wild food markets.

SARS-CoV-2 appears to be more easily transmissible than SARS-CoV and MERS-CoV. Consequently, early efforts to contain the virus were unsuccessful and it spread rapidly. The earliest secondary outbreaks were identified in Iran, Italy and Spain, but most of the world was affected within a few weeks (Fig. 13.17). The World Health Organization declared COVID-19 to be a global pandemic in March 2020, just 3 months after it was first identified in China. By late 2020 new variants had emerged carrying several amino acid substitutions. As the virus mutates variants of interest and variants of concern have been identified to aid public health measures to monitor transmission and research. The nomenclature of new variants developed alongside the pandemic. The variants were initially assigned 'Pango' lineage codes (letters and numbers) or identified with designations associated with clade (GISAID or Nexstrain), although as these were difficult for the public to use the variants tended to be referred to according to the geographic location where they were first identified, e.g. B.1.1.7 ('Kent', United Kingdom), B.1.351 (South Africa) and P.1 (Brazil). In May 2021, to both simplify the nomenclature and avoid the pejorative connotations of geographic associations, the WHO started to assign Greek characters to the variants, and these strains were named Alpha (e.g. B.1.1.7), Beta (e.g. B.1.351), Gamma (e.g. P.1) and Delta (e.g. B.1.617.2). The Greek letter names are designed to facilitate discussion in non-scientific audiences and do not replace the scientific names. The variants have higher R numbers than the native virus and are more transmissible due to mutations in the receptor-binding domain of the S protein, such as the replacement of asparagine with tyrosine at amino acid position 501 (N501Y). B.1.1.7 (Alpha) was found to cause increased mortality compared to previous SARS-CoV-2 strains in several studies. Mutation may also modify interactions with antibody, as suggested for the E484K mutation (where a glutamic acid residue is replaced by lysine) found in the Beta and Gamma variants. The highly transmissible B.1.617.2 (Delta) variant emerged in December 2020 causing a '2nd wave' in India before spreading across the world. The pattern was repeated in November 2021 with the B.1.1.529 (Omicron) variant, first reported in South Africa. However, Omicron tended to cause disease of less severity than earlier variants, presumably because of a combination of altered virulence factors and herd immunity from vaccination and natural infection.

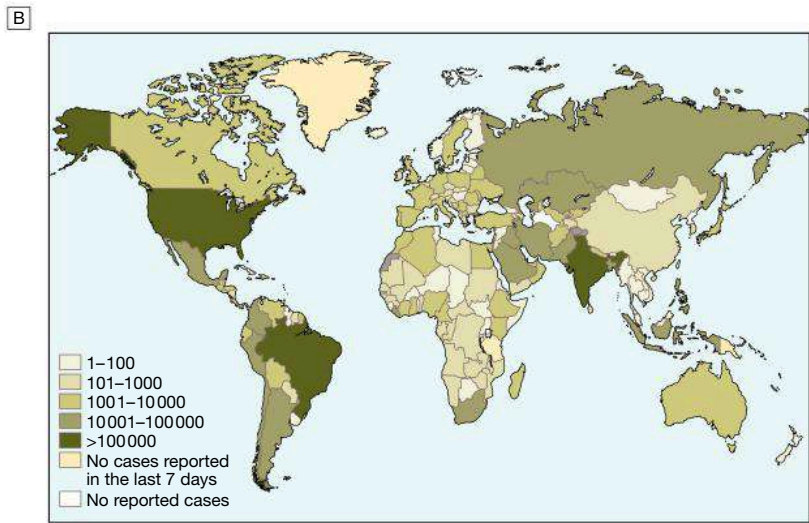

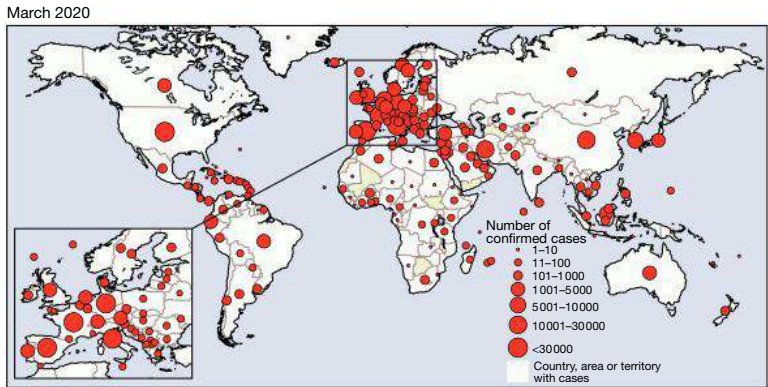

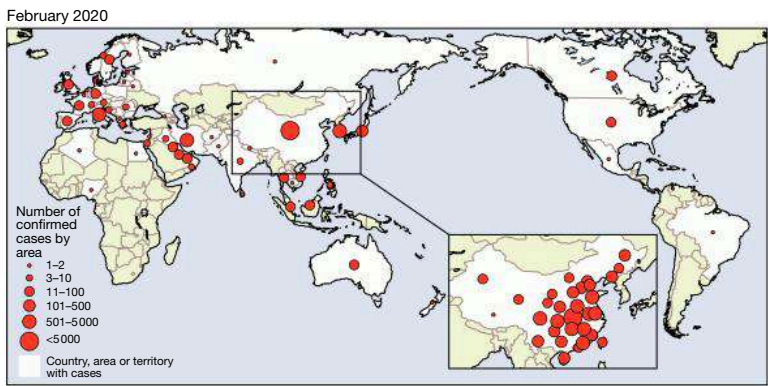

As well as exhibiting differences in transmissibility, symptomatology and case-fatality, infection by the variants is prevented to different extents by the separate COVID-19 vaccines available. For example, the Delta variant was found to have a greater propensity to infect individuals who had received only single doses of vaccines, most of which are designed to be given as a two-dose 'course'; and the Omicron variant had a propensity to infect people who were fully vaccinated but had not had 'booster' doses. SARS-CoV-2 is therefore very much a 'moving target' with respect to disease prevention strategies.

#### Responses to control the pandemic

The rapid emergence and exponential increase in COVID-19 case numbers as the pandemic developed raised significant challenges to the control of its transmission in both health-care settings and the wider community. Particular infection prevention and control (IPC) challenges raised by the pandemic included the rapid depletion of personal protective equipment (PPE), the lag between the spread of

**Fig. 13.17** Global spread of COVID-19 in 2020. **A** The spread of COVID-19 from late January with an epicentre in China to foci in Asia and Europe in late February, with more widespread cases in late March is shown, while in **B** the established pandemic is shown in July 2020. Redrawn with permission from WHO.

### 13.36 Infection prevention and control strategies used for COVID-19 in the health-care setting\*

<b>'Standard' precautions</b>	<ul style="list-style-type: none"> <li>• Hand hygiene</li> <li>• Use of personal protective equipment (PPE), e.g. masks, gloves, aprons, gowns and eye protection, according to the clinical circumstances</li> <li>• Spillage, sharps, laundry and clinical waste management</li> <li>• Environmental cleaning and disinfection</li> </ul>
<b>Transmission-based precautions</b>	<ul style="list-style-type: none"> <li>• A combination of airborne, contact and droplet precautions (see Box 6.9) with airborne precautions often reserved for situations in which aerosol-generating procedures (AGPs) are carried out</li> <li>• Different precautions may be applied depending on the level of patient risk (e.g. confirmed vs. suspected COVID-19)</li> </ul>
<b>Isolation, cohorting and quarantining</b>	<ul style="list-style-type: none"> <li>• Isolation or cohorting to minimise the risk of onward transmission (cohorting should be reserved for confirmed cases, or it carries the risk of uninfected patients being exposed to infected patients)</li> <li>• Quarantining patients prior to elective procedures</li> <li>• Quarantining staff who test positive for SARS-CoV-2</li> </ul>
<b>Screening</b>	<ul style="list-style-type: none"> <li>• Admission screening to identify asymptomatic infected patients</li> <li>• Interval screening of inpatients to identify and prevent health care-acquired COVID-19</li> <li>• Pre-procedure screening for patients having elective procedures</li> <li>• Staff screening to identify asymptomatic infected staff</li> </ul>
<b>Visitor restriction</b>	<ul style="list-style-type: none"> <li>• To minimise the possibility of uninfected patients being infected by visitors, and vice versa</li> </ul>
<b>Contact tracing</b>	<ul style="list-style-type: none"> <li>• Detection (and subsequent isolation) of uninfected patients who have been exposed to infected patients (e.g. in a bay/hospital ward) and staff</li> </ul>
*Infection prevention and control measures vary with time, in different countries and according to resource availability.	

infection and the acquisition of evidence required to inform IPC precautions to control its spread, the requirement by health-care providers to implement frequent changes in IPC guidance in response to the availability of PPE, and huge fluctuations in case numbers as the periodic introduction and relaxation of population-based control measures brought about 'waves' of infection, which had the potential to repeatedly overwhelm the ability of health services to function effectively.

#### Infection prevention and control in health-care settings

SARS-CoV-2 is acquired predominantly from the oropharyngeal and respiratory secretions of infected patients. Respiratory transmission has traditionally been categorized into 'airborne' (or 'aerosol') and 'droplet' spread, which are distinguished by the size of respiratory particles in which viable organisms are carried, with a cut-off size of 5 µm. The theoretical basis for the distinction is that particles of 5–10 µm diameter ('respiratory droplets') tend to fall out of the air soon after being produced. They are therefore unlikely to travel more than 1 m or so from the source patient and are transmitted mainly by settling on mucous membranes (direct transmission) or by being transported to mucous membranes via fomites (indirect transmission). Conversely, particles of <5 µm ('droplet nuclei') can remain suspended in the air for prolonged periods of time and can therefore travel longer distances and be taken into air passages by inhalation. In reality, both the size of respiratory particles produced by an infected person and the distance they can travel is likely to fall on a spectrum. The range of particle sizes will be affected by factors such as the speed of the passage of air across the infected person's respiratory tract mucous membranes, the volume and character of secretions being produced and the extent to which droplets are converted to droplet nuclei by evaporation; and the duration of airborne suspension and distance travelled will be influenced by environmental factors such as temperature, humidity and prevailing air currents. Therefore, the distinction between airborne/aerosol and droplet transmission is not absolute, and different precautions may be required for the same infection in different circumstances.

SARS-CoV-2 is believed to be predominantly transmitted by droplet spread in most circumstances (e.g. when an infected patient is breathing rapidly or coughing) but can be transmitted by the airborne route when the patient is subjected to an 'aerosol-generating procedure' (AGP). AGPs include (but are not limited to) tracheal intubation, manual ventilation, non-invasive ventilation and the use of certain high flow oxygenation treatments. For this reason, in the UK (at the time of writing) 'droplet'

precautions are considered adequate for the management of patients with COVID-19 (and other infections transmitted in a similar manner, such as influenza) in most circumstances, but 'airborne' precautions are used when an infected (or suspected) patient is subjected to an AGP. Unfortunately, the evidence-base for the distinction between airborne and droplet transmission in any given circumstance is weak and subject to repeated interpretation, so precautions used for COVID-19 tend to vary with time and geographical location.

The control of COVID-19 in health-care settings therefore requires a combination of measures, as shown in [Box 13.36](#).

#### Public health measures

A major strategy for limiting spread of SARS-CoV-2 has been the introduction of physical distancing measures, the most extreme of which have been termed 'lockdowns'. The components and restrictiveness of lockdowns vary between countries, but they have typically included: the closure of schools, workplaces, non-essential shops, sporting and entertainment venues; a move to remote (i.e. computer-based) working where possible; banning mass gatherings; curfews; stay-at-home orders; and other local, national and international travel restrictions. Not all countries have employed lockdowns. Physical distancing measures are designed to slow the spread of the virus and limit the burden of serious illness on overstretched health services, rather than to eradicate the virus. However, in some countries where they were employed early (e.g. New Zealand), they resulted in complete, although temporary, eradication of virus in the community.

Other important measures in limiting virus spread are ensuring high levels of case identification, ramping up testing to identify cases, ensuring public health follow-up of potential cases and enforcing quarantine measures for cases, contacts and travellers from high-incidence countries. The combination of such strategies has been termed 'test, trace and isolate' (TTI). Countries have tended to increase TTI measures as they have eased lockdowns, in an attempt to prevent rebound increases in cases and the need for subsequent lockdowns, which are economically damaging. Novel approaches to TTI have been developed, including the use of mobile phone apps, CCTV footage and tracking of a contact's digital signature, depending on jurisdiction and legal constraints. Surveillance sampling of all adults combined with advice to stay at home have been implemented as measures against emerging variant viruses.

Social distancing strategies employed when lockdown is not considered necessary have included keeping people physically separate (a target of ≥2 metres has been used in the UK), promoting frequent

hand hygiene and enforcing the use of face coverings in places where close contact is likely.

Vulnerable adults, including older and immunocompromised people, have been advised to limit social interactions, a strategy termed 'shielding' in the UK.

### Clinical features

The incubation period for COVID-19 is 5-6 days on average but can range from 2-14 days. Many infections, probably between 80% and 90%, are asymptomatic. Where patients do experience symptoms, these are very variable and depend on the vaccination status of the patient and the SARS-CoV-2 variant with which they are infected.

In unvaccinated patients and with variants predominating in the first year of the pandemic, typical symptoms include high fever, persistent cough, shortness of breath and loss of taste or smell. Myalgia, fatigue, dizziness or headache are also frequent, as are chest pain, vomiting and diarrhoea. Vomiting and diarrhoea may be prominent features and may precede fever, and gastrointestinal symptoms are often also prominent in children. Confusion or delirium occur, particularly in older people. Variant strains seen in the UK are associated with a greater range of symptoms, for example cough, sore throat, fatigue, myalgia and headaches appear more common, whereas loss of smell or taste are less common, than with the original virus. Variant B.1.17.2 (Delta) became the dominant variant in many countries by summer 2021, and commonly presented with coryzal symptoms, myalgia and headache, with cough and loss of taste or smell being a less common presentation.

Before the introduction of vaccination, approximately 15% of symptomatic patients would develop severe symptoms and 5% critical illness. Physical examination of such patients may reveal tachycardia, hypotension, cyanosis, hypoxia or bilateral crackles in the lung fields. Bronchial breath sounds and focal consolidation may suggest bacterial superinfection. Skin lesions are common and include maculopapular lesions, vesicles, pustules and urticarial lesions. Chilblain-like lesions with oedema or haemorrhage under the skin are also described. The differential diagnosis with a predominant respiratory presentation will include community-acquired pneumonia, influenza and other severe respiratory virus infections, including MERS-CoV.

If complications occur they usually develop in the second week. These are most commonly due to acute respiratory distress syndrome (ARDS). Bacterial pneumonia complicates a minority of infections and sepsis may occur. Superinfections occur, in particular in those with critical illness, including fungal infection due to *Aspergillus*, for which prolonged intubation is a risk factor. In India especially, mucormycosis (p. 345) emerged as a specific complication, especially in patients with pre-existing diabetes mellitus who were treated with steroids. Disseminated intravascular coagulation is seen in the majority of those who do not survive and is associated with severe disease and multi-organ failure. Venous thromboembolism occurs in 20%–30% of critically ill patients but may occur in any patients.

Microthrombi can form in the lung and some have proposed the term 'microvascular COVID-19 lung vessels obstructive thrombo-inflammatory syndrome' (MicroCLOTS) to distinguish this syndrome from conventional pulmonary embolism. Acute myocardial injury is reported in 5%–31% and acute coronary syndromes, myocarditis or arrhythmia occur. Acute kidney injury is common in hospitalised patients and up to a third of those requiring mechanical ventilation may require renal dialysis. Neurological complications are diverse and include cerebrovascular disease, cerebral venous thrombosis, meningitis, encephalitis, seizures, impaired consciousness, ataxia, neuropathies and Guillain-Barré syndrome. Rhabdomyolysis and secondary bacterial infections can occur. Hypothyroidism can be a long-term complication.

A striking characteristic of SARS-CoV-2 is its varying severity in different age groups. In broad terms the severity of infection ranges from mild or asymptomatic in children (in whom a fatal outcome is exceedingly rare) to severe and life-threatening in older adults. A specific but

### 13.37 Features of COVID-19 in older age and frailty

- **Pathogenesis:** reduced expression of hACE2 may predispose to more severe respiratory presentation
- **Immunity:** increased inflammatory responses in general and reduced antiviral responses may reduce viral clearance and increase complications
- **Clinical features:** atypical presentations with confusion, delirium and falls
- **Complications:** increased complication rates
- **Mortality:** case fatality rate doubled in those > 65 years and increases with age
- **Investigations:** lack of data on PCR sensitivity in older age
- **Treatment:** may be less likely to be admitted to intensive care
- **Preventative strategies:** more likely to be asked to 'shield' (minimise social interaction), with consequences for general well-being. Older adults are associated with lower vaccine responses in other diseases

rare manifestation in children is the 'paediatric inflammatory multisystem syndrome: temporally associated with SARS-CoV-2' (PIMS-TS), also referred to as multisystem inflammatory syndrome in children (MIS-C). This severe complication consists of fever, abdominal symptoms, rash, conjunctivitis and markers of a high inflammatory response. Myocardial dysfunction, shock and respiratory failure are common complications, and some children meet a clinical definition of Kawasaki disease with features such as coronary artery dilatation or vascular aneurysms. This syndrome appears distinct from Kawasaki disease, however, since it involves an older age group with more marked elevation of inflammatory biomarkers, and is associated with COVID-19. There is also a variant of MIS in adults.

The true case fatality rate for SARS-CoV-2 infection is not known because the apparent incidence of disease is influenced by many different factors. These factors include sampling strategies (i.e. testing a larger number of asymptomatic individuals will reduce the apparent mortality); the definition of a COVID-19-associated death (which varies with both time and jurisdiction); the period of follow-up or extent to which late deaths are attributed to COVID-19; the stage of the pandemic at which sampling was carried out (as mortality has fallen with the introduction of specific treatments); and the proportion of vaccinated vs. unvaccinated cases (as mortality is much lower in patients infected post-vaccination). However, at the time of writing there have been 4.6 million deaths and 222 million confirmed cases (2.1% overall mortality). The case fatality rate is therefore lower than for SARS-CoV and MERS-CoV, which have 11% and 34% mortality, respectively. Where death occurs, it is most often in the third week due to respiratory failure.

Virus is shed in respiratory secretions for approximately 17–24 days. Infection rates appear higher in urban or socially deprived areas. Mortality is higher with male gender, age and frailty (Box 13.37) and medical comorbidity (e.g. diabetes, heart disease, hypertension, chronic lung disease). In the UK mortality is higher in people with African Caribbean and South Asian origin, compared to individuals who have primarily European ancestry. A genome-wide association study linked severity to blood group A as opposed to blood group O, as well as a gene cluster in chromosome 3 that includes several chemokine receptors. The role of immunocompromise on COVID-19 is still being established. Immunocompromised patients may have atypical presentations and prolonged viral shedding, but may be less susceptible to severe COVID-19 if they are on anti-inflammatory treatments that modify COVID-19 pathogenesis. Early data suggested that patients immunosuppressed due to cancer or organ transplant recipients may present with more severe disease, while those receiving biologics do not. Increased age and medical comorbidity are associated with severe disease and mortality, and care homes have experienced outbreaks with high mortality.

'Long COVID' is a term that has been used to describe both prolonged COVID-19 and a post-COVID-19 syndrome that may involve almost any body system. In the UK, the National Institute for Health and Care Excellence (NICE) has defined acute COVID-19 as 'signs and symptoms of COVID-19 for up to 4 weeks', ongoing symptomatic COVID-19 as

'signs and symptoms of COVID-19 from 4 to 12 weeks' and the post-COVID-19 syndrome as 'signs and symptoms that develop during or after an infection consistent with COVID-19, continue for more than 12 weeks and are not explained by an alternative diagnosis'. 'Long COVID' would encompass the latter two scenarios. The World Health Organization has developed a definition for 'post COVID-19 condition' that specifies a symptom duration of at least two months, with symptoms being either a continuation of the initial infection or new symptoms after initial recovery. This too would accord with the popular understanding of 'long COVID'. Whatever definition is used, the most common unifying feature of long COVID/the post-COVID syndrome is fatigue, which can be prolonged and extreme. Other common presentations have included multisystem inflammatory symptoms, persistent fevers and evidence of organ dysfunction affecting almost any organ, but particularly the heart and lungs. Persistent headache, memory problems, insomnia and mental health symptoms such as depression are frequently reported, as are loss of taste and smell, deafness and tinnitus, arthralgia, skin rashes and paraesthesiae. In reality, the post-COVID syndrome is likely to be a conflation of different conditions, not all of which are specific to COVID-19 (e.g. COVID-19 itself, the sequelae of complications of COVID-19 and the various causes of ICU acquired weakness, p. 215). Optimal management strategies for long COVID have not yet been established.

### Investigations

Laboratory abnormalities can include an increased neutrophil to lymphocyte ratio; elevated ALT, D-dimer and inflammatory markers, including C-reactive protein (CRP) and ferritin; hypoalbuminaemia and lymphopenia. However, these findings are non-specific and of very little help in distinguishing COVID-19 from other infections. Procalcitonin (PCT) may be elevated and may raise suspicion of secondary bacterial infection, though there is currently insufficient evidence to recommend its routine use or on which to base decisions on whom to give antimicrobials on this test. Acute kidney injury is common in severe disease. Hypokalaemia and hypocalcaemia are common. Hyperglycaemia is also reported and may be observed in patients not known to be diabetic. Hypoxia may be accompanied by hypocapnia so that it appears inappropriately well tolerated ('happy hypoxia').

Chest radiology shows bilateral predominantly basal and peripheral infiltrates, or in a minority, unilateral infiltrates. CT scan of the chest shows 'ground glass' abnormalities, consolidation, septal thickening or crazy-pavement patterning (Fig. 13.18). Lesions are most often basal, peripheral and bilateral. Pulmonary vascular enlargement, pleural or pericardial effusions may be observed in a minority. CT changes may occur in those with negative chest radiography and negative PCR and can be used in patients in whom COVID-19 is strongly suspected but not confirmed. In general CT is reserved for severe cases or those with other indications for performing a CT.

Microbiological diagnosis is by nasopharyngeal or oropharyngeal swab and reverse-transcription PCR (RT-PCR) to detect viral RNA. Sensitivity is approximately 60%–70% and specificity is high (approximately 98%). Nasotracheal aspirates or deep sputum samples may have greater sensitivity. Antibody detection can confirm prior exposure but may cross-react with antibodies from other coronaviruses. Lateral flow immunochromatography (p. 106) is also used to detect SARS-CoV-2 antigens. It is rapid (around 30 minutes) and can be used at home but is less sensitive and specific than PCR.

### Management

Treatment is supportive, with high flow oxygen and proning. Non-invasive ventilation or mechanical ventilation are required for those with more severe respiratory failure. Fluid resuscitation is frequently required for hospitalised patients and antimicrobials are added if there are signs or symptoms suggestive of secondary infection. Inotropic support may be required for shock. Renal replacement therapy may be required for acute kidney injury, and anticoagulation if there is evidence of venous thromboembolism. Dexamethasone improves survival and is recommended for hospitalised patients requiring supplemental oxygen or mechanical ventilation. Anti-interleukin (IL)-6 monoclonal antibodies (e.g. tocilizumab) reduce mortality and reduce time to recovery in critically ill patients if administered within 24 hours of admission to an intensive care unit. In the UK tocilizumab is also used in patients with oxygen saturations <92% on repeated measurement on room air with a CRP  $\geq 75$  mg/L. An initial randomised clinical trial of the nucleotide analogue remdesivir (Chapter 6) found that it decreased the time to recovery when used within 10 days of symptom onset in patients requiring supplemental oxygen but not mechanical ventilation. However, it has not been found to significantly improve survival and is not currently recommended by the WHO. Antiviral agents are being developed with the goal of administering these early after symptom onset to prevent the later inflammatory complications. Preliminary trial results indicate that the oral antiviral agents molnupiravir and Paxlovid reduce hospitalisation and death if given within the first 3–5 days of symptoms. Molnupiravir is a prodrug, which is metabolised into a form that causes viral RNA-dependent RNA polymerase to introduce fatal mutations into nascent RNA strands. Paxlovid is a combination of two protease inhibitors, the investigational compound PF-07321332, and ritonavir; PF-07321332 is targeted against SARS-CoV-2 3CL protease and ritonavir inhibits the breakdown of PF-07321332. However, both drugs remain experimental at the time of writing, and there are many other potential SARS-CoV-2 antiviral agents at various stages of development. An alternative antiviral strategy is to use antibodies against the virus. The use of single monoclonal antibodies to variable regions of the S protein is limited by rapid emergence of viral resistance and they have not demonstrated efficacy. In contrast, combinations of two monoclonal antibodies (e.g. casirivimab and imdevimab (REGEN-COV)

**Fig. 13.18** Chest computerised tomography (CT) scan of a patient with COVID-19. The images show widespread areas of consolidation in both lungs.

### 13.38 SARS-CoV-2 vaccines licensed or at a late stage of development\*

Manufacturer	Vaccine type	Number of doses administered	Reported efficacy	Storage requirements
Oxford/AstraZeneca	Viral vector, ChAdOx (chimpanzee adenovirus)	2	62%–90%	4°C
Moderna	mRNA	2	95%	–20°C
Pfizer–BioNTech	mRNA	2	95%	–70°C
Gamaleya (Sputnik V)	Viral vector, Ad5 and Ad26 (human adenoviruses)	2	92%	4°C
Janssen (Johnson & Johnson)	Viral vector, Ad26 (human adenovirus)	1	66%	4°C
Novavax	Protein subunit	2	95%	4°C
Sinopharm	Inactivated virus	2	80%	4°C
Sinovac	Inactivated virus	2	50%	4°C
Sinopharm–Wuhan	Inactivated virus	2	70%	4°C
Bharat Biotech	Inactivated virus	2	80%	4°C

\*This list was accurate at the time of writing (mid-2021). However, because of the rapid speed of vaccine development this is not a complete list of available SARS-CoV-2 vaccines.

or bamlanivimab and etesevimab) are anticipated to represent a greater barrier to escape mutants and preserve efficacy. Initial studies demonstrate these reduce viral load and medical visits in outpatients and reduce hospital stay length and mortality in patients who have not mounted a natural antibody response following vaccination. The efficacy of monoclonal antibodies against the S protein may be challenged by the emergence of variants with mutations such as E484K, and approaches being developed in response include the use of 'broadly neutralizing' antibodies that target more conserved regions of the S protein. Trials using convalescent serum have not shown efficacy.

#### Vaccination

Because of the global impact of the SARS-CoV-2 pandemic vaccine development started very soon after the virus was identified and sequenced. Vaccines approved or in development include inactivated vaccines, RNA and DNA vaccines, protein subunit vaccines and recombinant RNA vaccines delivered in virus vectors (Box 13.38). The SARS-CoV-2 vaccines induce T-cell immunity in addition to neutralizing antibody but the extent and longevity as well as the ability to block transmission are still being assessed. In general, vaccines have been shown to be efficacious and some have reported efficacy against variant strains after single doses, although the efficacy of single dose vaccination is markedly reduced for the B.1.617.2 (Delta) variant. Vaccines have a more dramatic effect on reduction of hospitalised cases than they do on reduction of overall infection but they still play a major role in reducing community transmission. Vaccines are being developed to combat variant strains, including potentially addition of booster doses with modified RNA vaccines. Vaccines have demonstrated safety after billions of administered doses. Side-effects have been minimal and dwarfed by the ongoing mortality of COVID-19 in those without vaccination. Reported severe complications have occurred at incidences approximating 1 per million or less. At least two of the adenoviral vector COVID-19 vaccines have been linked to very rare cases of thrombosis with thrombocytopenia ('vaccine-induced thrombosis with thrombocytopenia syndrome (TTS)'), a condition with some similarities to heparin-induced thrombocytopenia (p. 948). Guillain-Barré syndrome is also reported after the adenoviral vaccines. The RNA vaccines have been linked to rare cases of myocarditis and pericarditis.

Vaccination programmes were rolled out at different rates in different countries. The strategy of rollout used in the UK and some other countries was to target the highest-risk demographic groups first (e.g. older people and those with underlying health conditions). As infection is less severe in patients who have been vaccinated, this strategy gradually converted COVID-19 from a severe disease with high mortality affecting the older population to a predominantly non-severe disease

with low mortality affecting younger people. Other strategies may have been used in different countries. The duration of immunity conferred by vaccines and natural infection is not yet known, and booster doses are likely to be required depending on the evidence that emerges.

The need to maintain the 'cold chain' from manufacture to administration is vital for any vaccine. However, it is a particular challenge the pure RNA SARS-CoV-2 vaccines, as they need to be stored at either –20°C or –70°C at all times. This is likely to reduce their use in low- and middle-income countries, where the logistical infrastructure required to maintain the cold chain is less likely to be available.

'Vaccine hesitancy' refers to a heterogeneous process in which individuals may refuse or delay vaccination. Vaccine hesitancy has been encountered in many countries and may be more prominent in populations with demographics that vary in different regions. This can represent a major challenge to ensuring high levels of vaccine uptake in a population.

#### Other considerations

The COVID-19 pandemic has necessitated changes in the law, e.g. to enable governments to mandate the use of masks in public, enforce lockdowns and streamline the processes of death certification to deal with surges in deaths. It has caused health services to become overwhelmed with acutely ill patients, with a knock-on effect of delaying the treatment of less urgent cases. An as yet unquantified problem is the burden of psychological illness in staff who work in patient-facing roles with COVID-19 patients and face issues such as physical exhaustion, burnout and post-traumatic stress disorder (PTSD).

### Viral infections with neurological involvement

See also page 1175.

#### Japanese encephalitis virus (JEV)

This flavivirus is an important cause of endemic encephalitis in Japan, China, Russia, South-east Asia, India and Pakistan; outbreaks also occur elsewhere. There are 10 000–20 000 cases reported to the WHO annually. Pigs and aquatic birds are the reservoirs and transmission is by *Culex* mosquitoes. Exposure to rice paddies is a recognised risk factor.

#### Clinical features

The incubation period is 4–21 days. Most infections are subclinical in childhood and 1% or less of infections lead to encephalitis. Initial systemic illness with fever, malaise and anorexia is followed by headache,

photophobia, vomiting and changes in brainstem function. Other neurological features include meningism, seizures, cranial nerve palsies, flaccid or spastic paralysis and extrapyramidal syndromes. Mortality with neurological disease is 25%. Some 50% of survivors have neurological sequelae.

### Investigations, management and prevention

Other infectious causes of encephalitis should be excluded. There is neutrophilia and often hyponatraemia. CSF analysis reveals lymphocytosis and elevated protein. Serological testing of serum and CSF aids diagnosis but may cross-react with dengue and other flaviviruses.

Treatment is supportive. Vaccination is recommended for travellers to endemic areas during the monsoon. Some endemic countries include vaccination in their childhood schedules.

### Tick-borne encephalitis virus

This flavivirus is endemic in an area from northern Europe (including the UK) that extends across Siberia to China and Japan. Its incidence is increasing, and it is transmitted from domestic or wild animals by *Ixodes* ticks or sometimes by unpasteurised dairy products. The incubation period is up to 28 days but averages 7 days. A third of cases cause symptoms, with fever, myalgia and headache followed by an interval of up to a month before meningitis, encephalitis or radiculitis occur. The Far Eastern sub-type tends to be more severe. Diagnosis is by IgM ELISA or detection of viral RNA by RT-PCR of blood or CSF. IgG serology cross-reacts with other flaviviruses. Treatment is supportive. Prevention is by avoidance of tick bites. A vaccine is also available.

### West Nile virus

This flavivirus is an important cause of neurological disease throughout Australia, India and Russia through Africa and Southern Europe and across to North America. The disease has an avian reservoir and a *Culex* mosquito vector. Older people are at increased risk of neurological disease.

#### Clinical features

Most infections are asymptomatic. After 2–6 days' incubation, a mild febrile illness and arthralgia may occur. A prolonged incubation may be seen in immunocompromised individuals. Children may develop a maculopapular rash. Neurological disease is seen in 1% and is characterised by encephalitis, meningitis or asymmetric flaccid paralysis with 10% mortality.

#### Diagnosis and management

Diagnosis is by serology or detection of viral RNA in blood or CSF. Serological tests may show cross-reactivity with other flaviviruses, including vaccine strains. Treatment is supportive.

### Nipah virus encephalitis

Nipah virus is a paramyxovirus in the Henipavirus genus, which caused an epidemic of encephalitis in Malaysia and subsequently outbreaks in Bangladesh and India. Mortality is around 30%. Diagnosis is by PCR or serology.

### Human T-cell lymphotropic virus type I

Human T-cell lymphotropic virus type I (HTLV-1) is a retrovirus that causes chronic infection with development of adult T-cell leukaemia/lymphoma (ATL) or HTLV-1-associated myelopathy (HAM) in a subset of those infected (see Box 25.57). It is found mainly in Japan, the Caribbean, Central and South America, and the Seychelles. The lifetime risk of ATL in those with chronic HTLV-1 infection is estimated at 2.5%–4%. HAM or tropical spastic paraparesis occurs in less than 5% of those with chronic infection, and presents with gait disturbance, spasticity of the lower extremities, urinary incontinence, impotence and sensory disturbance. Myositis and uveitis may also occur with HTLV-1

infection. Serology, sometimes confirmed with PCR, establishes the diagnosis. Treatment is supportive.

## Viral infections with rheumatological involvement

Rheumatological syndromes characterise a variety of viral infections ranging from exanthems, such as rubella and parvovirus B19, to blood-borne viruses, such as HBV and HIV-1 and the sequelae of EVD.

### Chikungunya virus

Chikungunya is an alphavirus that causes fever, rash and arthropathy. The disease occurs mainly in Africa and throughout Asia, but is becoming commoner in other areas, including South America and the Caribbean. Cases occur sporadically or in epidemics, with notable epidemics occurring in Réunion and Mauritius (>272 000 cases in 2005–06) and India (1 400 000 cases in 2006). Humans and non-human primates are the main reservoir. The vectors are *Aedes* mosquitoes including *Ae. aegyptii* and *Ae. albopictus*.

The incubation period is 2–12 days. A period of fever may be followed by an afebrile phase and then recrudescence of fever. Children may develop a maculopapular rash. Adults are susceptible to arthritis, which causes early morning pain and swelling, most often in the small joints. Arthritis can persist for months and may become chronic in individuals who are positive for human leucocyte antigen (HLA)-B27. Related alphaviruses causing similar syndromes include Sindbis virus (Scandinavia and Africa), O'nyong-nyong virus (Central Africa), Ross River virus (Australia) and Mayaro virus (Caribbean and South America).

Diagnosis is by serology but cross-reactivity between alphaviruses occurs. Treatment is symptomatic. The disease may be debilitating but is rarely fatal.

## Prion diseases

Prions cause transmissible spongiform encephalopathies and are discussed in Chapter 28.

## Bacterial infections

### Bacterial infections of the skin, soft tissues and bones

Most infections of the skin, soft tissues and bone are caused by either *Staph. aureus* or streptococci (mainly *Strep. pyogenes*) (see pp. 1025 and 1090).

### Staphylococcal infections

Staphylococci are usually found colonising the anterior nares and skin. Some staphylococci produce coagulase, an enzyme that converts fibrinogen to fibrin in rabbit plasma, causing it to clot. *Staph. aureus* is coagulase-positive, and most other species are coagulase-negative.

*Staph. aureus* is the main cause of staphylococcal infections. *Staphylococcus intermedius* is another coagulase-positive staphylococcus, which causes infection following dog bites. Among coagulase-negative organisms, *Staphylococcus epidermidis* is the predominant commensal organism of the skin, and can cause severe infections in those with central venous catheters or implanted prosthetic materials. *Staphylococcus saprophyticus* is part of the normal vaginal flora and causes urinary tract infections in sexually active young women. *Staphylococcus lugdunensis*, *Staphylococcus schleiferi*, *Staphylococcus haemolyticus* and *Staphylococcus caprae* are also human pathogens.

Staphylococcal blood-stream infections can disseminate widely (Fig. 13.19). In any patient with staphylococcal bacteraemia, especially

**Fig. 13.19** Infections caused by *Staphylococcus aureus*. (CNS = central nervous system)

injection drug-users, the possibility of endocarditis must be considered (see p. 462). Growth of *Staph. aureus* in blood cultures should not be dismissed as a 'contaminant'. Spreading cellulitis mandates the urgent need for an antistaphylococcal antibiotic, such as flucloxacillin, cefazolin or a glycopeptide if MRSA is suspected. This is particularly true for mid-facial cellulitis, which can result in cavernous sinus thrombophlebitis.

In addition, *Staph. aureus* can cause severe systemic disease due to the effects of toxin produced at superficial sites in the absence of tissue invasion by bacteria.

### Skin infections

Staphylococci cause ecthyma, folliculitis, furuncles, carbuncles, bullous impetigo and the scalded skin syndrome, which are discussed in Chapter 27. They may also be involved in necrotising infections of the skin and subcutaneous tissues.

### Wound infections

Many wound infections, which prolong post-operative care, are caused by staphylococci (Fig. 13.20A). Prevention involves careful attention to hand hygiene, skin preparation and aseptic technique, and the use of topical and systemic antibiotic prophylaxis.

Treatment is by early drainage of any abscesses, removal of prosthetic materials if possible, plus adequate dosage of antistaphylococcal antibiotics.

### Cannula-related infection

Staphylococcal infection associated with cannula sepsis (Fig. 13.20B) and thrombophlebitis is an important and common reason for morbidity following hospital admission. The visual infusion phlebitis (VIP) score aids cannula evaluation (Box 13.39). Staphylococci have a predilection for plastic, rapidly forming a biofilm on cannulae, which is a source of bacteraemia. Local poultice application may relieve symptoms but cannula removal and antibiotic treatment with flucloxacillin (or a glycopeptide) are necessary if there is spreading infection.

### Meticillin-resistant *Staphylococcus aureus*

Resistance to meticcillin is due to a penicillin-binding protein mutation in *Staph. aureus*, which confers resistance to almost all  $\beta$ -lactam antibiotics.

**Fig. 13.20** Manifestations of skin infection with *Staphylococcus aureus*. **A** Wound infection. **B** Cannula-related infection.

13.39 How to assess an intravenous (IV) cannula using the visual infusion phlebitis (VIP) score		
Clinical features	Score	Assessment and management
IV site appears healthy	0	<b>No signs of phlebitis</b> Observe cannula
One of the following is evident: Slight pain near IV site Slight redness near IV site	1	<b>Possible first signs of phlebitis</b> Observe cannula
Two of the following are evident: Pain near IV site Erythema Swelling	2	<b>Early stage of phlebitis</b> Resite cannula
ALL of the following are evident and extensive: Pain along path of cannula Erythema Induration	3	<b>Medium stage of phlebitis</b> Resite cannula Consider treatment
ALL of the following are evident and extensive: Pain along path of cannula Erythema Induration Palpable venous cord	4	<b>Advanced stage of phlebitis or start of thrombophlebitis</b> Resite cannula Consider treatment
ALL of the following are evident: Pain along path of cannula Erythema Induration Palpable venous cord Pyrexia	5	<b>Advanced stage of thrombophlebitis</b> Initiate treatment Resite cannula

*Adapted from Jackson A. Infection control: a battle in vein infusion phlebitis. Nursing Times 1997; 94:68–71.*

Resistance to vancomycin/teicoplanin (glycopeptides) in either glycopeptide intermediate *Staph. aureus* (GISA) or, rarely, vancomycin-resistant (VRSA) strains threatens management of serious staphylococcal infections. Meticillin-resistant *Staph. aureus* (MRSA) is now a major worldwide health care-acquired pathogen, accounting for up to 40% of staphylococcal bacteraemia in high-income countries. Community-acquired MRSA (c-MRSA) currently accounts for 50% of all MRSA infections in the USA. These organisms have also acquired other toxins, such as Panton-Valentine leukocidin (PVL), and can cause rapidly fatal infection in young people. Clinicians must be aware of the potential danger of these infections and implement appropriate locally approved infection control measures.

Treatment options for MRSA are shown in Box 6.16. Treatment should always be based on the results of antimicrobial susceptibility testing, since resistance to all these agents occurs. Milder MRSA infections may be

treated with clindamycin, tetracyclines or co-trimoxazole. Glycopeptides, linezolid and daptomycin are reserved for treatment of more severe infections. Toxin-producing MRSA infections should be treated with the addition of protein-inhibiting antibiotics (clindamycin, linezolid).

### Staphylococcal toxic shock syndrome

Staphylococcal toxic shock syndrome (TSS) is a life-threatening disease associated with infection by *Staph. aureus* producing a specific toxin (toxic shock syndrome toxin 1, TSST1). Formerly seen in young women in association with the use of highly absorbent intravaginal tampons, it can occur with any infection involving a TSST1-producing *Staph. aureus* strain. The toxin acts as a 'super-antigen', triggering significant T-cell activation and massive cytokine release.

TSS has an abrupt onset with high fever, generalised systemic upset (myalgia, headache, sore throat and vomiting), a widespread erythematous blanching rash resembling scarlet fever, and hypotension. It rapidly progresses over a few hours to multi-organ failure, leading to death in 10%–20%. Recovery is accompanied at 7–10 days by desquamation (Fig. 13.21).

The diagnosis is clinical and may be confirmed in menstrual cases by finding a retained tampon with staphylococci on Gram stain. Subsequent culture and demonstration of toxin production are confirmatory.

### Management

Treatment is with immediate and aggressive fluid resuscitation and an intravenous antistaphylococcal antimicrobial, usually with the addition of a protein synthesis inhibitor (e.g. clindamycin) to inhibit toxin production. Intravenous immunoglobulin is occasionally added in the most severe cases. Women who recover from tampon-associated TSS should avoid tampons for at least 1 year and they should be advised that the condition can recur.

## Streptococcal infections

Streptococci are oropharyngeal and gut commensals, which appear as Gram-positive cocci in chains (see Fig. 6.3). They were classified by the pattern of haemolysis they produce on blood agar (see Fig. 6.4), by their 'Lancefield serogroups' (Box 13.40) but are now usually identified and classified by matrix-assisted laser desorption/ionisation time-of-flight (MALDI-TOF) mass spectrometry. Some streptococci (e.g. *Strep. milleri* group) defy simple classification.

*Strep. pyogenes* (group A streptococcus, GAS) is the leading cause of bacterial pharyngitis. Although the presence of fever, tender anterior lymphadenopathy and purulent tonsillar exudate and the absence of cough make streptococcal pharyngitis more likely than viral infection, clinical features alone are unreliable for diagnosing streptococcal pharyngitis. GAS are the major cause of cellulitis, erysipelas and impetigo. They also cause the post-streptococcal syndromes of glomerulonephritis and rheumatic fever, which are described in Chapters 14 and 16, respectively. The closely related *Streptococcus dysgalactiae* subsp. *equisimilis* (SDSE) (formerly groups C and G) cause cellulitis, particularly in older people, diabetic or immunocompromised patients. *Streptococcus agalactiae* (group B streptococci (GBS)) colonise the gut and vagina. They cause post-partum and neonatal sepsis, as well as other deep infections (infective endocarditis, septic arthritis, osteomyelitis etc.), especially in older people.

### Streptococcal scarlet fever

*Strep. pyogenes* (or occasionally SDSE) causing pharyngitis, tonsillitis or other infection may lead to scarlet fever, if the infecting strain produces a streptococcal pyrogenic exotoxin. Scarlet fever is most common in school-age children, but can also occur in young adults who have contact with young children. A diffuse erythematous rash occurs, which blanches on pressure (Fig. 13.22A), classically with circumoral pallor. The tongue, initially coated, becomes red and swollen ('strawberry tongue', Fig. 13.22B). The disease lasts about 7 days, the rash disappearing in 7–10 days, followed by a fine desquamation. Residual petechial lesions in the antecubital fossa, 'Pastia's sign', can occur (Fig. 13.22C).

Treatment involves intravenous benzylpenicillin or an oral penicillin plus symptomatic measures.

Fig. 13.21 Full-thickness desquamation after staphylococcal toxic shock syndrome.

## 13.40 Streptococcal and related infections

### β-haemolytic group A (*Streptococcus pyogenes*)

- Skin and soft tissue infection (including erysipelas, impetigo, necrotising fasciitis)
- Streptococcal toxic shock syndrome
- Puerperal sepsis
- Scarlet fever
- Glomerulonephritis
- Rheumatic fever
- Bone and joint infection
- Tonsillitis

### β-haemolytic streptococci group B (*Strep. agalactiae*)

- Neonatal infections, including meningitis
- Female pelvic infections
- Cellulitis

### β-haemolytic streptococci groups C and G

- Cellulitis
- Endocarditis
- Pharyngitis
- Septic arthritis

### α-, β- or non-haemolytic group D (*Enterococcus faecalis*, *E. faecium*)

- Endocarditis
- Intra-abdominal infections
- Urinary tract infection

### α- or non-haemolytic group D (*Strep. gallolyticus* subsp. *gallolyticus*/S. bovis biotype I)

- Bacteraemia/endocarditis associated with large bowel malignancy

### α-haemolytic optochin-resistant (viridans streptococci – *Strep. mitis*, *Strep. sanguis*, *Strep. mutans*, *Strep. salivarius*)

- Sepsis in immunosuppressed
- Endocarditis

### α-haemolytic optochin-sensitive (*Strep. pneumoniae*)

- Pneumonia
- Meningitis
- Endocarditis
- Otitis media
- Sepsis
- Spontaneous bacterial peritonitis
- Sinusitis

### Variable haemolysis (*Strep. milleri* group – *Strep. anginosus*, *Strep. intermedius*, *Strep. constellatus*)

- Endocarditis
- Intra-abdominal infections
- Urinary tract infection

### Anaerobic streptococci (*Peptostreptococcus* spp.)

- Sepsis in immunosuppressed
- Endocarditis

**N.B.** All streptococci can cause sepsis.

**Fig. 13.22** Clinical features of scarlet fever. **A** Characteristic rash with blanching on pressure. **B** 'Strawberry tongue'. **C** Pastia's sign: a petechial rash in the cubital fossa.

### Streptococcal toxic shock syndrome

*Strep. pyogenes* and SDSE can produce one of a variety of toxins, such as streptococcal pyogenic exotoxin A. Like staphylococcal TSST1 (see above), these act as super-antigens. Initially, an influenza-like illness occurs, with signs of localised infection in 50% of cases, most often involving the skin and soft tissues. A faint erythematous rash, mainly on the chest, rapidly progresses to circulatory shock. Without aggressive management, multi-organ failure will develop.

Judicious fluid resuscitation is combined with parenteral antistreptococcal antibiotic therapy, usually with benzylpenicillin and clindamycin, to inhibit toxin production. Intravenous immunoglobulin is often administered. If necrotising fasciitis is present, it should be treated as described on page 272 with urgent débridement.

## Treponematoses

### Syphilis

This disease is described in Chapter 15.

### Endemic treponematoses

#### Yaws

Yaws is a granulomatous disease, mainly involving the skin and bones, caused by *Treponema pertenuis*. It is morphologically and serologically indistinguishable from the microorganisms causing syphilis and pinta. The geographical origin and sexual history of patients helps exclude false-positive syphilis serology due to endemic treponemal infections. Between 1950 and 1960, WHO campaigns treated over 60 million people and eradicated yaws from many areas, but the disease has persisted throughout the tropics. A resurgence occurred in the 1980s and 1990s in West and Central Africa and the South Pacific.

Organisms are transmitted by bodily contact from a patient with infectious yaws through minor skin abrasions of the recipient, usually a child. After 3–4 weeks' incubation, a proliferative granuloma containing numerous treponemes develops at the inoculation site. This primary lesion is followed by secondary eruptions. In addition, there may be hypertrophic periosteal bone lesions, with underlying cortical rarefaction. Lesions of late yaws are characterised by destructive changes that closely resemble the osteitis and gummas of tertiary syphilis. These heal with scarring and deformity. Investigations and management are outlined in [Box 13.41](#). Improved housing and hygiene, combined with mass chemotherapy programmes, have achieved dramatic success in the control of yaws.

#### Pinta and bejel

These two treponemal infections occur in poor rural populations with low standards of domestic hygiene but are found in separate parts of the world. They have features in common, notably that they are transmitted

i 13.41 Diagnosis and treatment of yaws, pinta and bejel	
<b>Diagnosis of early stages</b>	<ul style="list-style-type: none"> <li>Detection of spirochaetes in exudate of lesions by dark ground microscopy</li> </ul>
<b>Diagnosis of latent and early stages</b>	<ul style="list-style-type: none"> <li>Positive serological tests, as for syphilis (see <a href="#">Box 15.8</a>)</li> </ul>
<b>Treatment of all stages</b>	<ul style="list-style-type: none"> <li>Single intramuscular injection of 1.2g long-acting penicillin, e.g. benzathine benzylpenicillin</li> </ul>

by contact, usually within the family and not sexually, and in the case of bejel, through common eating and drinking utensils. Their diagnosis and management are as for yaws (see [Box 13.41](#)).

- *Pinta*. Pinta is found only in South and Central America, where its incidence is declining. The infection is confined to the skin. The early lesions are scaly papules or dyschromic patches on the skin. The late lesions are often depigmented and disfiguring.
- *Bejel*. Bejel is the Middle Eastern name for non-venereal syphilis, which has a patchy distribution across sub-Saharan Africa, the Middle East, Central Asia and Australia. It has been eradicated from Eastern Europe. Transmission is most commonly from the mouth of the mother or child and the primary mucosal lesion is seldom seen. The early and late lesions resemble those of secondary and tertiary syphilis but cardiovascular and neurological disease is rare.

#### Tropical ulcer

Tropical ulcer is due to a synergistic bacterial infection caused by a fusobacterium (*Fusobacterium ulcerans*, an anaerobe) and *Treponema vincentii*. It is common in hot, humid regions. The ulcer commonly involves the lower legs, developing as a papule that rapidly breaks down to form a sharply defined, painful ulcer. The ulcer base has a foul slough. Penicillin and metronidazole are useful in the early stages but rest, elevation and dressings are the mainstays of treatment.

#### Buruli ulcer

*Mycobacterium ulcerans* causes Buruli ulcer in tropical rainforests. Cases were declining until 2016 but have risen since, with 2713 cases reported in 2018. Outside West and Central Africa occasional cases have been reported in Australia.

The initial lesion is a small subcutaneous nodule on the arm or leg. This breaks down to form a shallow, necrotic ulcer with deeply undermined edges, which extends rapidly. Healing may occur after 6 months but granuloma formation and the accompanying fibrosis cause contractures and deformity. Clumps of acid-fast bacilli are detected in the ulcer floor.

A combination of rifampicin and clarithromycin can cure the infection. Infected tissue should be removed surgically. Wound and lymphoedema management, surgery, including skin grafting, and physiotherapy all play a role in management and prevention of disability.

## Systemic bacterial infections

### Brucellosis

Brucellosis is an enzootic infection (i.e. endemic in animals) caused by Gram-negative coccobacilli. The four species causing human disease and their animal hosts are: *Brucella melitensis* (goats, sheep and camels in Europe, especially the Mediterranean basin, the Middle East, Africa, India, Central Asia and South America), *B. abortus* (cattle, mainly in Africa, Asia and South America), *B. suis* (pigs in South Asia) and *B. canis* (dogs). *B. melitensis* causes the most severe disease; *B. suis* is often associated with abscess formation.

Infected animals may excrete *Brucella* spp. in their milk for prolonged periods and human infection is acquired by ingesting contaminated dairy products (especially unpasteurised milk), uncooked meat or offal. Animal urine, faeces, vaginal discharge and uterine products may transmit infection through abraded skin or via splashes and aerosols to the respiratory tract and conjunctiva.

#### Clinical features

*Brucella* spp. are intracellular organisms that survive for long periods within the reticulo-endothelial system. This favours chronicity and relapse, even after antimicrobial therapy.

Acute illness is characterised by a high swinging temperature, rigors, lethargy, headache, arthralgia, myalgia and scrotal pain. Occasionally, there is delirium, abdominal pain and constipation. Physical signs are non-specific, e.g. enlarged lymph nodes. Splenomegaly may cause thrombocytopenia.

Localised infection (Fig. 13.23) occurs in approximately 30% of patients, particularly if treatment is delayed.

#### Diagnosis

Definitive diagnosis depends on culture of the organism. Blood cultures are positive in 75%–80% of *B. melitensis* and 50% of *B. abortus*

infections. Bone marrow culture is not routine but may increase the diagnostic yield if antibiotics have been used prior to culture. CSF culture in neurobrucellosis is positive in about 30% of cases. The laboratory should be informed of suspected brucellosis, to allow appropriate laboratory steps to prevent laboratory worker infection.

Serology may aid diagnosis. In endemic areas, a single high antibody titre of more than 1/320 or a fourfold rise in titre supports a diagnosis of acute infection. The test usually takes several weeks to become positive but should eventually detect 95% of acute infections.

#### Management

Aminoglycosides show synergistic activity with tetracyclines and treatment regimens for different forms of brucellosis are outlined in Box 13.42.

### Borrelia infections

*Borrelia* are flagellated spirochaetal bacteria that infect humans after bites from ticks or lice. They cause a variety of human infections worldwide (Box 13.43).

#### Lyme disease

Lyme disease is caused by *B. burgdorferi*, which occurs in the USA, Europe, Russia, China, Japan and Australia. In Europe, two additional genospecies are also encountered, *B. afzelii* and *B. garinii*. The reservoir of infection is ixodid (hard) ticks that feed on a variety of large mammals, particularly deer. Birds spread ticks over a wide area. The organism is transmitted to humans via the bite of larval, nymphal or adult ticks.

Ehrlichiosis is a common co-infection with Lyme disease. Two forms occur: *Anaplasma phagocytophilum*, human granulocytic anaplasmosis (HGA); and *Ehrlichia chaffeensis*, human monocytic ehrlichiosis (HME).

#### Clinical features

There are three stages of disease. Progression may be arrested at any stage.

- **Early localised disease.** The characteristic feature is a skin reaction around the site of the tick bite, known as erythema migrans (Fig. 13.24). Initially, a red 'bull's eye' macule or papule appears 2–30 days after the bite. It then enlarges peripherally with central

clearing and may persist for months. Atypical forms are common. The lesion is not pathognomonic of Lyme disease since similar lesions can occur after tick bites. Acute manifestations, such as fever, headache and regional lymphadenopathy, may develop with or without the rash.

- **Early disseminated disease.** Dissemination occurs via the blood stream and lymphatics. There may be a systemic reaction with malaise, arthralgia and, occasionally, metastatic areas of erythema migrans (see Fig. 13.24). Neurological involvement may follow weeks or months after infection. Common features include lymphocytic meningitis, cranial nerve palsies (especially unilateral or bilateral facial nerve palsy) and peripheral neuropathy. Radiculopathy, often painful, may present a year or more after initial infection. Carditis, sometimes accompanied by atrioventricular conduction defects, occurs in the USA but is rare in Europe.
- **Late disease.** Late manifestations include arthritis, polyneuritis and encephalopathy. Prolonged arthritis, particularly affecting large joints, and brain parenchymal involvement, causing neuropsychiatric abnormalities, may occur but are rare in the UK. Acrodermatitis chronica atrophicans is an uncommon late complication seen more frequently in Europe than North America. Doughy, patchy discoloration occurs on the peripheries, eventually leading to shiny atrophic skin. The lesions are mistaken for those of peripheral vascular disease. In patients with facial nerve palsy coming from an endemic area or having risk factors, Lyme disease should be excluded.

#### Diagnosis

The diagnosis of early Lyme borreliosis is clinical. Culture from biopsy material is rarely available, has a low yield and may take over 6 weeks. Antibody detection is frequently negative early in the course of the disease but sensitivity increases to 90%–100% in disseminated or late disease. Immunofluorescence or ELISA can give false-positive reactions in a number of conditions, including other spirochaetal infections, infectious mononucleosis, rheumatoid arthritis and systemic lupus erythematosus (SLE). Immunoblot (Western blot) techniques are more specific and should be used to confirm the diagnosis. Microorganism DNA detection by PCR has been applied to blood, urine, CSF and biopsies of skin and synovium.

#### Management

Asymptomatic patients with positive antibody tests do not require treatment. However, erythema migrans always requires therapy because organisms may persist and cause progressive disease, even if the skin lesions resolve. Standard therapy consists of a 14-day course of doxycycline (200 mg daily) or amoxicillin (500 mg 3 times daily). Some 15% of patients with early disease will develop a mild febrile reaction (Jarisch-Herxheimer JHR) during the first 24 hours of therapy. In pregnant women and small children with penicillin allergy, or in those allergic to amoxicillin and doxycycline, 14-day treatment with cefuroxime axetil (500 mg twice daily) or azithromycin (500 mg once daily) may be used.

Disseminated disease and arthritis require therapy for a minimum of 28 days. Arthritis may respond poorly and prolonged or repeated courses may be necessary. Neuroborreliosis is treated with parenteral  $\beta$ -lactam antibiotics for 3–4 weeks; third-generation cephalosporins such as ceftriaxone are preferred.

### Prevention

Protective clothing and insect repellents should be used in tick-infested areas. Since the risk of borrelial transmission is lower in the first few hours of a blood feed, prompt removal of ticks is advisable. Unfortunately, larval and nymphal ticks are tiny and may not be noticed. Where risk of transmission is high, a single 200mg dose of doxycycline, given within 72 hours of exposure, has been shown to prevent erythema migrans.

### Louse-borne relapsing fever

The human body louse, *Pediculus humanus*, causes itching. Borreliae (*B. recurrentis*) are released from infected lice when they are crushed during scratching, inoculating borreliae into the skin. The disease occurs worldwide, with epidemic relapsing fever most often seen in Central/East Africa and South America.

The borreliae multiply in the blood, where they are abundant in the febrile phases, and invade most tissues, especially the liver, spleen and meninges.

### Clinical features

Onset is sudden with fever. The temperature rises to 39.5–40.5°C, accompanied by a tachycardia, headache, generalised aching, injected conjunctivae (Fig. 13.25) and herpes labialis. Thrombocytopenia is associated with a petechial rash and epistaxis. As the disease progresses tender hepatosplenomegaly, jaundice and elevated transaminases are common. There may be severe serosal and intestinal haemorrhage, delirium and meningism. The fever ends in crisis between the fourth and tenth days, often associated with profuse sweating, hypotension and circulatory and cardiac failure. Fever may resolve but, in a proportion of patients, after an afebrile period of about 7 days, there are one or more febrile relapses, which are usually milder and less prolonged. Without specific treatment, the mortality rate is up to 40%, especially among older and malnourished patients.

### Investigations and management

Dark ground microscopy of a wet film or Wright–Giemsa-stained thick and thin films demonstrate the organism in blood from a febrile patient.

Treatment aims to eradicate the organism and prevent relapses, while minimising the severe JHR that inevitably follows successful chemotherapy. The safest treatment is procaine penicillin 300mg intramuscularly, followed the next day by 0.5g tetracycline. Tetracycline alone is effective and prevents relapse, but may give rise to a worse reaction. Doxycycline 200mg once orally in place of tetracycline has the advantage of also being curative for typhus, which often accompanies epidemics of relapsing fever. JHR is best managed in a high-dependency unit with expert nursing and medical care.

The patient, clothing and all contacts must be freed from lice, as in epidemic typhus.

Fig. 13.25 Louse-borne relapsing fever. Injected conjunctivae.

### Tick-borne relapsing fever

Soft ticks (*Ornithodoros* spp.) transmit *B. duttonii* (and other *Borrelia* species) through saliva while feeding on their host. People sleeping in mud houses are at risk, as the tick hides in crevices during the day and feeds on humans during the night. Rodents are the reservoir except in East Africa, where humans are the reservoir. Clinical manifestations are similar to those seen with the louse-borne disease but microorganisms are detected in fewer patients on dark-field microscopy. A 7-day course (due to a higher relapse rate than in louse-borne relapsing fever) of treatment with either tetracycline (500mg 4 times daily) or erythromycin (500mg 4 times daily) is needed.

## Leptospirosis

### Microbiology and epidemiology

Leptospirosis is one of the most common zoonotic diseases, favoured by a tropical climate and flooding during the monsoon but occurring worldwide. Leptospire are tightly coiled, thread-like organisms about 5–7  $\mu$ m in length, which are actively motile; each end is bent into a hook. *Leptospira interrogans* is pathogenic for humans. The genus can be separated into more than 200 serovars (subtypes) belonging to 23 serogroups.

Leptospirosis is ubiquitous in wildlife and in many domestic animals. The organisms persist indefinitely in the convoluted tubules of the kidney and are shed into the urine in massive numbers, but infection is asymptomatic in the host. The most frequent hosts are rodents, especially the common rat (*Rattus norvegicus*). Particular leptospiral serogroups are associated with characteristic animal hosts; for example, *L. icterohaemorrhagiae* is the classical parasite of rats and *L. canicola* of dogs. There is nevertheless considerable overlap in host-serogroup associations.

Leptospire can penetrate intact skin or mucous membranes but human infection is facilitated by cuts and abrasions. Prolonged immersion in contaminated water facilitates invasion, as the spirochaete survives in water for months. Leptospirosis is common in the tropics and also in freshwater sports enthusiasts.

### Clinical features

After a relatively brief bacteraemia, invading organisms are distributed throughout the body, mainly in kidneys, liver, meninges and brain. The incubation period averages 1–2 weeks. Four main clinical syndromes can be discerned and clinical features can involve multiple different organ systems (Fig. 13.26).

#### Bacteraemic leptospirosis

Bacteraemia with any serogroup can produce a non-specific illness with high fever, weakness, muscle pain and tenderness (especially of the calf and back), intense headache and photophobia, and sometimes diarrhoea and vomiting. Conjunctival congestion is the only notable physical sign. The illness comes to an end after about 1 week, or else merges into one of the other forms of infection.

#### Aseptic meningitis

Classically associated with *L. canicola* infection, this illness is very difficult to distinguish from viral meningitis. The conjunctivae may be congested but there are no other differentiating signs. Laboratory clues include a neutrophil leucocytosis, abnormal LFTs and the occasional presence of albumin and casts in the urine.

#### Icteric leptospirosis (Weil's disease)

Fewer than 10% of symptomatic infections result in severe icteric illness. Weil's disease is a dramatic life-threatening event, characterised by fever, haemorrhages, jaundice and acute kidney injury. Conjunctival hyperaemia is a frequent feature. The patient may have a transient macular erythematous rash but the characteristic skin changes are purpura and large areas of bruising. In severe cases there may be epistaxis, haematemesis and melaena, or bleeding into the pleural, pericardial or

**Fig. 13.26** Clinical syndromes of leptospirosis. (ARDS = acute respiratory distress syndrome)

subarachnoid spaces. Thrombocytopenia, probably related to activation of endothelial cells with platelet adhesion and aggregation, is present in 50% of cases. Jaundice and hepatomegaly usually occur without hepatic failure or encephalopathy. Acute kidney injury, primarily caused by impaired renal perfusion and acute tubular necrosis, causes oliguria or anuria, with albumin, blood and casts in the urine.

Weil's disease may also be associated with myocarditis, encephalitis and aseptic meningitis. Uveitis and iritis may appear months after apparent clinical recovery.

#### Pulmonary syndrome

This syndrome has long been recognised in the Far East and has been described during an outbreak of leptospirosis in Nicaragua. It is characterised by haemoptysis, patchy lung infiltrates on chest X-ray, and respiratory failure. Total bilateral lung consolidation and ARDS with multi-organ dysfunction may develop, with a high mortality (over 50%).

#### Diagnosis

A polymorphonuclear leucocytosis is accompanied in severe infection by thrombocytopenia and elevated blood levels of creatine kinase. In jaundiced patients, there is hepatitis and the prothrombin time may be prolonged. The CSF in leptospiral meningitis shows a variable cellular response, a moderately elevated protein level and normal glucose content. Acute kidney injury due to interstitial nephritis is common.

In the tropics, dengue, malaria, typhoid fever, scrub typhus and hantavirus infection are important differential diagnoses.

Definitive diagnosis of leptospirosis depends on isolation of the organism, serological tests or detection of specific DNA. In general, however, it is probably under-diagnosed.

- Blood cultures are most likely to be positive if taken before day 10 of illness. Special media are required and cultures may have to be incubated for several weeks.
- Leptospire appear in the urine during the second week of illness, and in untreated patients may be recovered on culture for several months.
- Serological tests are diagnostic if seroconversion or a fourfold increase in titre is demonstrated. The microscopic agglutination test

(MAT) is the investigation of choice and can become positive by the end of the first week. IgM ELISA and immunofluorescent techniques are easier to perform, however, while rapid immunochromatographic tests are specific they are of only moderate sensitivity in the first week of illness.

- Detection of leptospiral DNA by PCR is possible in blood in early symptomatic disease, and in urine from day 8 of illness and for many months thereafter.

#### Management and prevention

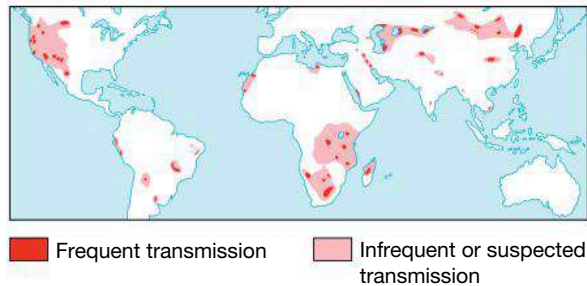

The general care of the patient is critically important. Blood transfusion for haemorrhage and careful attention to renal function, the usual cause of death, are especially important. Acute kidney injury is potentially reversible with adequate support, such as dialysis. Most infections are self-limiting. Therapy with either oral doxycycline (100 mg twice daily for 1 week) or intravenous penicillin (900 mg 4 times daily for 1 week) is effective but may not prevent the development of renal failure. Parenteral ceftriaxone (1 g daily) is as effective as penicillin. JHR may occur but is usually mild. Uveitis is treated with a combination of systemic antibiotics and local glucocorticoids. There is no role for the routine use of glucocorticoids in the management of leptospirosis.

Trials in military personnel have shown that infection with *L. interrogans* can be prevented by taking prophylactic doxycycline 200 mg weekly.

#### Plague

Plague is caused by *Yersinia pestis*, a small Gram-negative bacillus that is spread between rodents by their fleas. If domestic rats become infected, infected fleas may bite humans. Hunters and trappers can contract plague from handling rodents. In the late stages of human plague, *Y. pestis* may be expectorated and spread between humans by droplets, causing 'pneumonic plague'.

Epidemics of plague, such as the 'Black Death', have occurred since ancient times. It is often said that the first sign of plague is the appearance of dead rats. Plague foci are widely distributed throughout the world, including the USA; human cases are reported from about 10 countries per year (Fig. 13.27).

**Fig. 13.27** Foci of the transmission of plague. Reproduced by permission of the World Health Organization.

*Y. pestis* is a potential bioweapon because of the possibility of person-to-person spread and the high fatality rate associated with pneumonic plague.

### Clinical features

Organisms inoculated through the skin are transported rapidly to the draining lymph nodes, where they elicit a severe inflammatory response that may be haemorrhagic. If the infection is not contained, sepsis ensues and necrotic, purulent or haemorrhagic lesions develop in many organs. Oliguria and shock follow, and disseminated intravascular coagulation may result in widespread haemorrhage. Inhalation of *Y. pestis* causes alveolitis. The incubation period is 3–6 days but shorter in pneumonic plague.

### Bubonic plague

In this, the most common form of the disease, onset is usually sudden, with a rigor, high fever, dry skin and severe headache. Soon, aching and swelling at the site of the affected lymph nodes begin. The groin is the most common site of the 'bubo', a collection of swollen lymph nodes and surrounding tissue. Some infections are relatively mild but, in the majority, toxæmia quickly increases, with a rapid pulse, hypotension and delirium. The spleen is usually palpable.

### Septicaemic plague

Those without a bubo usually deteriorate rapidly, with high associated mortality. Older people are more prone to septicaemic plague. The patient is toxic and may have gastrointestinal symptoms, such as nausea, vomiting, abdominal pain and diarrhoea. DIC may occur, manifested by bleeding from various orifices or puncture sites, along with ecchymoses. Hypotension, shock, renal failure and ARDS may develop. Meningitis, pneumonia and expectoration of blood-stained sputum containing *Y. pestis* may complicate septicaemic, or occasionally bubonic, plague.

### Pneumonic plague

Following primary infection in the lung, the onset of disease is very sudden, with cough and dyspnoea. The patient expectorates copious blood-stained, frothy, highly infective sputum, becomes cyanosed and dies. Chest radiology reveals bilateral infiltrates, which may be nodular and progress to an ARDS-like picture.

### Investigations

The organism may be cultured from blood, sputum and bubo aspirates. For rapid diagnosis, Gram, Giemsa and Wayson's stains (the latter containing methylene blue) are applied to smears from these sites. *Y. pestis* is seen as bipolar staining coccobacilli, sometimes referred to as having a 'safety pin' appearance. Smears are also subjected to antigen detection by immunofluorescence, using *Y. pestis* F1 antigen-specific antibodies. The diagnosis may be confirmed by seroconversion or a single high titre (>128) of anti-F1 antibodies in serum. DNA detection by PCR is under evaluation.

Plague is a notifiable disease under international health regulations.

### Management

If the diagnosis is suspected on clinical and epidemiological grounds, treatment must be started as soon as, or even before, samples have been collected for laboratory diagnosis. Streptomycin (1g twice daily) or gentamicin (1 mg/kg 3 times daily) is the drug of choice. Tetracycline (500mg 4 times daily) and chloramphenicol (12.5mg/kg 4 times daily) are alternatives. Fluoroquinolones (ciprofloxacin and levofloxacin) may be as effective but there is less clinical experience. Treatment may also be needed for acute circulatory failure, DIC and hypoxia.

### Prevention and infection control

Rats and fleas should be controlled. In endemic areas, people should avoid handling and skinning wild animals. The patient should be isolated for the first 48 hours or until clinical improvement begins. Attendants must wear gowns, masks and gloves. Symptomatic or asymptomatic close contacts of cases of pneumonic plague should receive post-exposure antibiotic prophylaxis (doxycycline 100mg or ciprofloxacin 500mg twice daily) for 7 days.

A recombinant subunit vaccine (protein antigens F1 + V) is in development.

### Listeriosis

*Listeria monocytogenes* is an environmental Gram-positive bacillus that can contaminate food. Outbreaks have been associated with raw vegetables, soft cheeses, under-cooked chicken, fish, meat and pâtés. The bacterium demonstrates 'cold enrichment', outgrowing other contaminating bacteria during refrigeration. Although food-borne outbreaks of gastroenteritis have been reported in immunocompetent individuals, *Listeria* causes more significant invasive infection, especially in pregnant women, older adults (over 55 years) and the immunocompromised.

In pregnancy, in addition to systemic symptoms of fever and myalgia, listeriosis causes chorioamnionitis, fetal deaths, abortions and neonatal infection. In other susceptible individuals, it causes systemic illness due to bacteraemia without focal symptoms. Meningitis, similar to other bacterial meningitis but with normal CSF glucose, is the next most common presentation; CSF usually shows increased neutrophils but occasionally only the mononuclear cells are increased (see [Box 28.6](#)).

### Investigations and management

Diagnosis is made by blood and CSF culture. The organism grows readily in culture media.

The most effective regimen consists of a combination of intravenous amoxicillin or ampicillin plus an aminoglycoside. A sulfamethoxazole/trimethoprim combination can be used in those with penicillin allergy. Cephalosporins are of no use in this infection, as the organism is inherently resistant, an important consideration when treating meningitis empirically.

Proper treatment of foods before eating is the key to preventing listeriosis. Pregnant women are advised to avoid high-risk products, including soft cheeses.

### Enteric fevers (typhoid and paratyphoid)

Typhoid and paratyphoid fevers, which are transmitted by the faecal-oral route, are important causes of fever in South Asia, sub-Saharan Africa and Latin America. Elsewhere, they are relatively rare. Enteric fevers are caused by infection with *Salmonella enterica* serotypes Typhi and Paratyphi A, B and C, but invasive disease is occasionally observed with non-typhoidal *Salmonella* spp. After a few days of bacteraemia, the bacilli localise, mainly in the lymphoid tissue of the small intestine, resulting in typical lesions in the Peyer's patches and follicles. These swell at first, then ulcerate and usually heal. After clinical recovery, about 5% of patients become chronic carriers (i.e. continue to excrete the bacteria after 1 year); the bacilli may live in the gallbladder for months or years and pass intermittently in the stool and, less commonly, in the urine.

## Clinical features

### Typhoid fever

Clinical features are outlined in [Box 13.44](#). The incubation period is typically about 10–14 days but can be longer, and the onset may be insidious. The temperature rises in a stepladder fashion for 4 or 5 days with malaise, increasing headache, drowsiness and aching in the limbs. Constipation may be caused by swelling of lymphoid tissue around the ileocaecal junction, although in children diarrhoea and vomiting may be prominent early in the illness. The pulse is often slower than would be expected from the height of the temperature, i.e. a relative bradycardia.

At the end of the first week, a rash may appear on the upper abdomen and on the back as sparse, slightly raised, rose-red spots, which fade on pressure. Cough and epistaxis occur. Around the 7th–10th day, the spleen becomes palpable. Constipation is followed by diarrhoea and abdominal distension with tenderness. Bronchitis and delirium may develop. If untreated, by the end of the second week the patient may be profoundly ill.

### Paratyphoid fever

The course tends to be shorter than that of typhoid fever and the onset is often more abrupt, with acute enteritis. The rash may be more abundant and the intestinal complications less frequent.

## Complications

These are given in [Box 13.45](#). Haemorrhage from, or a perforation of, the ulcerated Peyer's patches may occur at the end of the second week or during the third week of the illness. A drop in temperature to normal or subnormal levels may be falsely reassuring in patients with intestinal haemorrhage. Additional complications may involve almost any viscus or system because of the bacteraemia present during the first week. Bone and joint infection is common in children with sickle-cell disease.

## Investigations

In the first week, diagnosis may be difficult because, in this invasive stage with bacteraemia, the symptoms are those of a generalised infection without localising features. Typically, there is a leucopenia. Blood culture establishes the diagnosis and multiple cultures increase the yield. Stool cultures are often positive in the second and third weeks. The Widal test detects antibodies to the O and H antigens but is not specific.

## Management

Antibiotic therapy must be guided by in vitro sensitivity testing. Chloramphenicol (500mg 4 times daily), ampicillin (750mg 4 times daily) and co-trimoxazole (960mg PO or IV twice daily) are losing their effect due to resistance in many areas of the world, especially in South and South-east Asia. Fluoroquinolones are the drugs of choice (e.g. ciprofloxacin 500mg twice daily), if nalidixic acid screening predicts susceptibility, but resistance is common, especially in South Asia and also in the UK. Extended-spectrum cephalosporins (ceftriaxone and cefotaxime) are useful alternatives but have a slightly increased treatment failure rate. Azithromycin (500mg once daily) is an alternative when fluoroquinolone resistance is present but has not been validated in severe disease. Treatment should be continued for 14 days. Extensively drug-resistant ('XDR') typhoid has been causing an ongoing outbreak in Pakistan since 2016 and azithromycin is the only currently reliable oral therapy. Pyrexia may persist for up to 5 days after the start of specific therapy. Even with effective chemotherapy, there is still a danger of complications, recrudescence of the disease and the development of a carrier state.

Chronic carriers were formerly treated for 4 weeks with ciprofloxacin but may require an alternative agent and duration, as guided by antimicrobial sensitivity testing. Cholecystectomy may be necessary.

## Prevention

Improved sanitation and living conditions reduce the incidence of typhoid. Travellers to countries where enteric infections are endemic

should receive typhoid vaccination. In young children a tetanus conjugate vaccine containing Vi polysaccharide conjugated to tetanus toxoid has over 80% efficacy and is superior to older inactivated injectable or oral live attenuated vaccines.

## Tularaemia

Tularaemia is primarily a zoonotic disease of the northern hemisphere. It is caused by a highly infectious Gram-negative bacillus, *Francisella tularensis*. *F. tularensis* is passed transovarially (ensuring transmission from parent to progeny) in ticks, which allows persistence in nature without the absolute requirement for an infected animal reservoir. It is a potential bioweapon. Wild rabbits, rodents and domestic dogs or cats are potential reservoirs, and ticks, mosquitoes or other biting flies are the vectors.

Infection is introduced either through an arthropod or animal bite or via contact with infected animals, soil or water through skin abrasions. The most common 'ulceroglandular' variety of the disease (70%–80%) is characterised by skin ulceration with regional lymphadenopathy. There is also a purely 'glandular' form. Alternatively, inhalation of the infected aerosols may result in pulmonary tularaemia, presenting as pneumonia. Rarely, the portal of entry of infection may be the conjunctiva, leading to a nodular, ulcerated conjunctivitis with regional lymphadenopathy (an 'oculoglandular' form). Typhoidal tularaemia is a rare and serious form of tularaemia with vomiting, diarrhoea and hepatosplenomegaly, which may be complicated by pneumonia and meningitis.

## Investigations and management

Demonstration of a single high titre ( $\geq 1:160$ ) or a fourfold rise in 2–3 weeks in the tularaemia tube agglutination test confirms the diagnosis. Bacterial yield from the lesions is extremely poor. DNA detection methods to enable rapid diagnosis are in development.

Treatment consists of a 10–21-day course of parenteral aminoglycosides, streptomycin (7.5–10 mg/kg twice daily) or gentamicin (1.7 mg/kg 3 times daily), with doxycycline or ciprofloxacin offered as alternatives.

## Melioidosis

Melioidosis is caused by *Burkholderia pseudomallei*, a saprophyte found in soil and water (rice paddy fields). Infection is by inoculation or inhalation, leading to bacteraemia, which is followed by the formation of abscesses in the lungs, liver and spleen. Patients with diabetes, renal stones, thalassaemia or severe burns are particularly susceptible. The disease is most common in South-east Asia and northern Australia, and carries a significant mortality. Disease may present years or decades after the initial exposure.

### Clinical features

Pneumonia is the most common feature but localised skin nodules and abscesses, or sepsis, especially in diabetics, may occur. Diarrhoea and hepatosplenomegaly may be observed. The chest X-ray can resemble cavitory tuberculosis. In chronic forms, multiple abscesses occur in subcutaneous tissue, liver, spleen and bone, accompanied by profound weight loss.

### Investigations and management

Culture of blood, sputum or pus on selective media, e.g. Ashdown agar, may yield *B. pseudomallei*. Latex agglutination has been developed as a rapid diagnostic test in Thailand and PCR-based tests are also available. Indirect haemagglutination testing can be helpful in travellers; however, most people in endemic areas are seropositive.

In the acute illness, prompt initiation of empirical therapy is life-saving. Ceftazidime 100 mg/kg (2 g 3 times daily) or meropenem (0.5–1 g 3 times daily) is given for 2–3 weeks, followed by maintenance therapy of cotrimoxazole (sulfamethoxazole 1600 mg plus trimethoprim 320 mg twice daily) or doxycycline 200 mg daily for 3–6 months. Abscesses should be drained surgically.

## Actinomycete infections

### Nocardiosis

Nocardiosis is caused by aerobic Actinomycetes of the genus *Nocardia*, found in the soil. Infection occurs follows direct traumatic inoculation or occasionally inhalation or ingestion. Nocardiosis can result in localised cutaneous ulcers or nodules, most often in the lower limbs. Chronic destructive infection in tropical countries can result in actinomycetoma, involving soft tissues with occasional penetration to the bone. Actinomycetoma may also be caused by other aerobic Actinomycetes, and a similar clinical syndrome, eumycetoma, is caused by filamentous fungi. Both conditions are discussed on page 344. Systemic *Nocardia* infection, most commonly in immunocompromised individuals, results in suppurative disease with lung and brain abscesses.

On microscopy, *Nocardia* spp. appear as long, filamentous, branching Gram-positive rods, which are also weakly acid-fast. They are easily grown in culture but require prolonged incubation.

Treatment of systemic infection is guided by sensitivity testing and typically requires combinations of imipenem with ceftriaxone, amikacin or co-trimoxazole, often for 6–12 months or longer. Meropenem, tigecycline, linezolid and minocycline may also be used with severe disease or with allergy, or when intolerance prevents use of the preferred agents. Abscesses are drained surgically when this is feasible. Localised cutaneous infection is usually treated with a single agent for 1–3 months. Treatment of actinomycetoma is discussed on page 344.

### Actinomyces spp.

*Actinomyces* are anaerobic Actinomycetes, which are predominantly commensals of the oral cavity. They are capable of causing deep, suppurating infection in the head and neck (cervicofacial actinomycosis) and the lungs (thoracic actinomycosis). They also cause suppurating disease in the pelvis, associated with intrauterine contraceptive devices (IUCDs). Modern diagnostic techniques demonstrate that actinomycosis is caused by many different *Actinomyces* species, the most common of which is *Actinomyces israelii*. Treatment of established disease requires approximately 6–12 months of penicillin or doxycycline. Early disease may respond to shorter antibiotic courses.

## Gastrointestinal bacterial infections

The approach to patients presenting with acute gastroenteritis is described on page 272.

### Staphylococcal food poisoning

*Staph. aureus* is transmitted via the hands of food handlers to food-stuffs such as dairy products, including cheese, and cooked meats. Inappropriate storage of these foods allows growth of the organism and production of one or more heat-stable enterotoxins.

Nausea and profuse vomiting develop within 1–6 hours. Diarrhoea may not be marked. The toxins that cause the syndrome act as 'super-antigens' and induce a significant neutrophil leucocytosis that may be clinically misleading. Most cases settle rapidly but severe dehydration can occasionally be life-threatening.

Antiemetics and appropriate fluid replacement are the mainstays of treatment. Suspect food should be cultured for staphylococci and demonstration of toxin production. Public health authorities should be notified if food vending is involved.

### Bacillus cereus food poisoning

Ingestion of pre-formed heat-stable exotoxins of *B. cereus* causes rapid onset of vomiting and some diarrhoea within hours of food consumption, which resolves within 24 hours. Fried rice and freshly made sauces are frequent sources; the organism grows and produces enterotoxin during storage (Fig. 13.28). If viable bacteria are ingested and toxin formation takes place within the gut lumen, then the incubation period is longer (12–24 hours) and watery diarrhoea and cramps are the predominant symptoms. The disease is self-limiting but can be severe.

Appropriate fluid replacement and notification of the public health authorities are indicated.

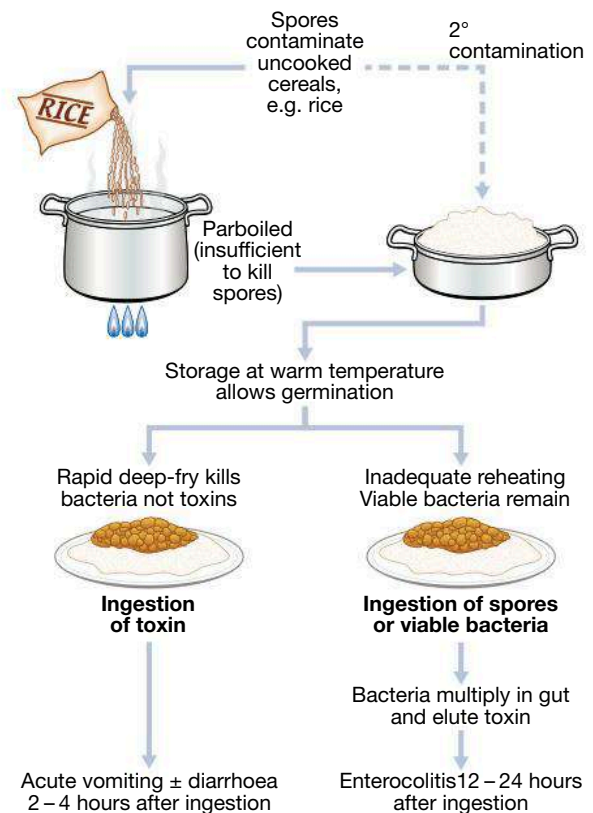

Fig. 13.28 *Bacillus cereus* food poisoning.

### ***Clostridium perfringens* food poisoning**

Spores of *C. perfringens* are widespread in the guts of large animals and in soil. If contaminated meat products are incompletely cooked and stored in anaerobic conditions, *C. perfringens* spores germinate and viable organisms multiply. Subsequent reheating of the food causes release of enterotoxin. Symptoms (diarrhoea and cramps) occur 6–12 hours following ingestion. The illness is usually self-limiting.

Clostridial enterotoxins are potent and most people who ingest them will be symptomatic. ‘Point source’ outbreaks, in which a number of cases all become symptomatic following ingestion, classically occur after school or canteen lunches where meat stews are served.

Clostridial necrotising enteritis (CNE) or pigbel is an often-fatal type of food poisoning caused by a  $\beta$ -toxin of *C. perfringens*, type C. The toxin is normally inactivated by certain proteases or by normal cooking. Pigbel is more likely in protein malnutrition or in the presence of trypsin inhibitors, either in foods such as sweet potatoes or during infection with *Ascaris* sp. roundworms.

### ***Campylobacter* infection**

This infection (caused by *Campylobacter jejuni* or *C. coli*) is essentially a zoonosis, although contaminated water may be implicated, as the organism can survive for many weeks in fresh water. The most common sources of the infection are chicken, beef and contaminated milk products. Pet puppies have also been sources. *Campylobacter* infection is now the most common cause of bacterial gastroenteritis in the UK, accounting for some 100 000 cases per annum, most of which are sporadic.

The incubation period is 2–5 days. Colicky abdominal pain may be severe and mimic acute appendicitis or other surgical pathology. Nausea, vomiting and significant diarrhoea, frequently containing blood, are common features. The majority of *Campylobacter* infections affect fit young adults and are self-limiting after 5–7 days. About 10%–20% will be prolonged, occasionally meriting treatment with a macrolide, most often azithromycin, as many organisms are resistant to ciprofloxacin.

Approximately 1 in 1000–2000 cases will develop bacteraemia and possible distant foci of infection. *Campylobacter* spp. have been linked to Guillain-Barré syndrome and post-infectious reactive arthritis (see Chs 26 and 28).

### ***Salmonella* spp. infection**

*Salmonella enterica* serovars other than Typhi and Paratyphi, of which there are more than 2000, are widespread in animals and can cause gastroenteritis. Two serovars are most important worldwide: *Salmonella* Enteritidis phage type 4 and *Salmonella* Typhimurium dt.104. The latter may be resistant to commonly used antibiotics such as ciprofloxacin. Some strains have a clear relationship to particular animals, e.g. *Salmonella* Arizonae and pet reptiles. Transmission is by contaminated water or food, particularly poultry, egg products and minced beef, direct person-to-person spread or the handling of exotic pets such as salamanders, lizards or turtles. The incidence of *Salmonella* enteritis is falling in the UK due to an aggressive culling policy in broiler chicken stocks, coupled with vaccination.

The incubation period of *Salmonella* gastroenteritis is 12–72 hours and the predominant feature is diarrhoea, sometimes with passage of blood. Vomiting may be present at the outset. Approximately 5% of cases are bacteraemic and invasive non-typhoidal salmonellosis is a leading cause of bacteraemia in sub-Saharan Africa especially in people living with HIV. Reactive (post-infective) arthritis occurs in approximately 2%.

Antibiotics are not indicated for uncomplicated *Salmonella* gastroenteritis but are prescribed for bacteraemia. Salmonellae can cause persistent infection and can seed endothelial surfaces such as an atherosclerotic aorta. Mortality, as with other forms of gastroenteritis, is higher in older people (see Box 13.11).

### ***Escherichia coli* infection**

Many serotypes of *E. coli* constitute part of the human gut microbiome. Clinical disease requires either colonisation with a new or previously unrecognised strain, or the acquisition by current colonising bacteria of a particular pathogenicity factor for mucosal attachment or toxin production. Travel to unfamiliar areas of the world allows contact with different strains of endemic *E. coli* and the development of travellers’ diarrhoea. Enteropathogenic strains may be found in the gut of healthy individuals and, if these people move to a new environment, close contacts may develop symptoms.

At least five different clinico-pathological patterns of diarrhoea are associated with specific strains of *E. coli* with characteristic virulence factors.

#### **Enterotoxigenic *E. coli***

Enterotoxigenic *E. coli* (ETEC) is the most common cause of travellers’ diarrhoea (see Box 13.19). The organisms produce either a heat-labile or a heat-stable enterotoxin, causing marked secretory diarrhoea and vomiting after 1–2 days’ incubation. The illness is usually mild and self-limiting after 3–4 days. Antibiotics are of questionable value.

#### **Enteroinvasive *E. coli***

Illness caused by enteroinvasive *E. coli* (EIEC) is very similar to *Shigella* dysentery and is caused by invasion and destruction of colonic mucosal cells. No enterotoxin is produced. Acute watery diarrhoea, abdominal cramps and some scanty blood-staining of the stool are common. The symptoms are rarely severe and are usually self-limiting.

#### **Enteropathogenic *E. coli***

Enteropathogenic *E. coli* (EPEC) organisms are very important in infant diarrhoea. They are able to attach to the gut mucosa, inducing a specific ‘attachment and effacement’ lesion and causing destruction of microvilli and disruption of normal absorptive capacity. The symptoms vary from mild non-bloody diarrhoea to quite severe illness without bacteraemia.

#### **Enteropathogenic *E. coli***

Enteropathogenic *E. coli* (EPEC) organisms are very important in infant diarrhoea. They are able to attach to the gut mucosa, inducing a specific ‘attachment and effacement’ lesion and causing destruction of microvilli and disruption of normal absorptive capacity. The symptoms vary from mild non-bloody diarrhoea to quite severe illness without bacteraemia.

#### **Enterohaemorrhagic *E. coli***

A number of distinct ‘O’ serotypes of *E. coli* possess both the genes necessary for adherence (see ‘EPEC’ above) and plasmids encoding two distinct enterotoxins (verotoxins), which are identical to the toxins produced by *Shigella* (‘shiga toxins 1 and 2’). *E. coli* O157:H7 is perhaps the best known of these verotoxin-producing *E. coli* (VTEC) but others, including types O126 and O11, are also implicated. In 2011, an outbreak of food-borne illness linked to fenugreek seeds occurred in Germany and was due to *E. coli* O104:H4, an EAEC strain that had acquired genes encoding shiga toxin 2a. Although the incidence of enterohaemorrhagic *E. coli* (EHEC) is considerably lower than that of *Campylobacter* and *Salmonella* infection, it is increasing in lower-income countries.

The reservoir of infection is in the gut of herbivores. The organism has an extremely low infecting dose (10–100 organisms). Runoff water from pasture lands where cattle have grazed, which is used to irrigate vegetable crops, as well as contaminated milk, meat products (especially hamburgers that have been incompletely cooked), lettuce, radish shoots and apple juice have all been implicated as sources (Fig. 13.29).

The incubation period is 1–7 days. Initial watery diarrhoea becomes uniformly blood-stained in 70% of cases and is associated with severe abdominal pain. There is little systemic upset, vomiting or fever.

Enterotoxins have both a local effect on the bowel and a distant effect on particular body tissues, such as renal glomeruli, heart and brain. The potentially life-threatening haemolytic uraemic syndrome (HUS) occurs in

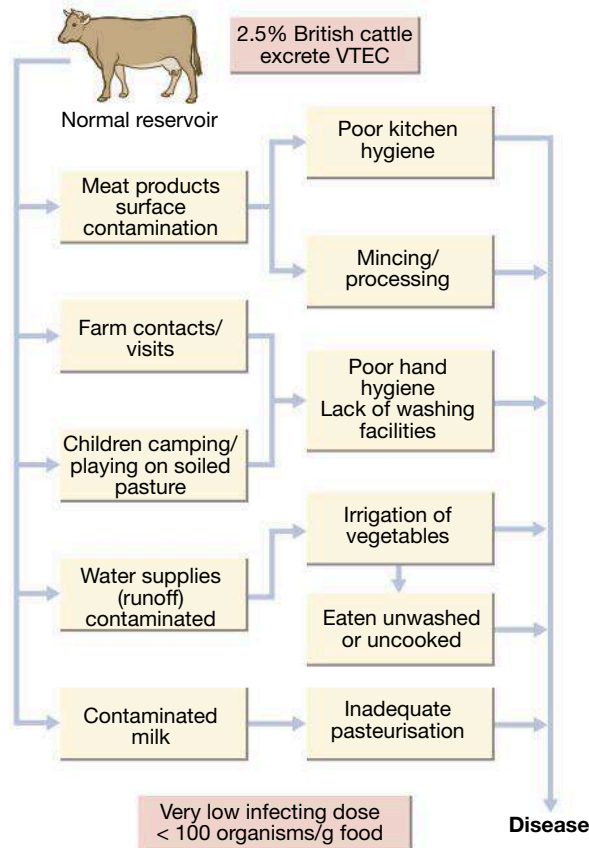

Fig. 13.29 Verocytotoxigenic *Escherichia coli* (VTEC) infections.

10%–15% of sufferers from this infection, arising 5–7 days after symptom onset. It is most frequent at the extremes of age, is heralded by a high peripheral leucocyte count, and may be induced, particularly in children, by antibiotic therapy.

HUS is treated by dialysis if necessary and may be averted by plasma exchange. Antibiotics should be avoided since they can stimulate toxin release.

### *Clostridioides difficile* infection

*Clostridioides* (formerly *Clostridium*) *difficile* is the most common cause of antibiotic-associated diarrhoea, and is an occasional constituent of the gut microbiome. *C. difficile* can produce two toxins (A and B). *C. difficile* infection (CDI) usually follows antimicrobial therapy, which alters the composition of the gastrointestinal flora and may facilitate colonisation with toxigenic *C. difficile*, if the patient is exposed to *C. difficile* spores. The combination of toxin production and the ability to produce environmentally stable spores accounts for the clinical features and transmissibility of CDI. A hypervirulent strain of *C. difficile*, ribotype 027, has emerged, which produces more toxin and more severe disease than other *C. difficile* strains.

#### Clinical features

Disease manifestations range from diarrhoea to life-threatening pseudomembranous colitis. Around 80% of cases occur in people over 65 years of age, many of whom are frail with comorbid diseases. Symptoms usually begin in the first week of antibiotic therapy but can occur up to 6 weeks after treatment has finished. The onset is often insidious, with lower abdominal pain and diarrhoea that may become profuse and watery. The presentation may resemble acute ulcerative colitis with bloody diarrhoea, fever and even toxic dilatation and perforation. Ileus is also seen in pseudomembranous colitis.

Fig. 13.30 *Clostridioides difficile* infection. Colonoscopic view showing numerous adherent 'pseudomembranes' on the mucosa.

#### Investigations

*C. difficile* can be isolated from stool culture in 30% of patients with antibiotic-associated diarrhoea and over 90% of those with pseudomembranous colitis, but also from 5% of healthy adults and up to 20% of older adults in residential care. The diagnosis of CDI therefore rests on detection of toxins A or B in the stool. Current practice in the UK is to screen stool from patients with a compatible clinical syndrome by detection either of glutamate dehydrogenase (GDH), an enzyme produced by *C. difficile*, or of *C. difficile* nucleic acid (e.g. by PCR); if screening is positive, *C. difficile* toxin is sought, usually with a sensitive ELISA assay.

The rectal appearances at sigmoidoscopy may be characteristic, with erythema, white plaques or an adherent pseudomembrane (Fig. 13.30), or may resemble ulcerative colitis. In some cases, the rectum is spared and abnormalities are observed in the proximal colon. Patients who are ill require abdominal and erect chest X-rays to exclude perforation or toxic dilatation. CT may be useful when the diagnosis is in doubt.

#### Management

The precipitating antibiotic should be stopped and the patient should be isolated. Supportive therapy includes intravenous fluids and bowel rest. First-line antimicrobial therapy is usually vancomycin (125 mg orally 4 times daily for 7–10 days), which has replaced the use of metronidazole. Fidaxomicin is associated with a lower relapse rate than vancomycin but is more expensive. Intravenous immunoglobulin and/or glucocorticoids are sometimes given in the most severe or refractory cases, and faecal transplantation from a healthy donor is increasingly used to manage relapses by restoring a more advantageous gut microbiome profile. Bezlotoxumab is a monoclonal antibody against toxin B designed to prevent recurrence but its current role is uncertain. Surgical intervention needs to be considered early in severe cases.

#### Yersiniosis

*Yersinia enterocolitica* and *pseudotuberculosis*, commonly found in pork, cause mild to moderate gastroenteritis and can produce significant mesenteric adenitis after an incubation period of 3–7 days. They predominantly cause disease in children but adults may also be affected. The illness resolves slowly and may be mistaken for appendicitis (pseudoperitonitis). Complications include reactive arthritis (10%–13% of cases), which may be persistent, and anterior uveitis.

## Cholera

Cholera, caused by *Vibrio cholerae* serotype O1, is the archetypal toxin-mediated bacterial cause of acute watery diarrhoea. The enterotoxin activates adenylate cyclase in the intestinal epithelium, inducing net secretion of chloride and water. *V. cholerae* O1 has two biotypes, classical and El Tor, and each of these has two distinct serotypes, Inaba and Ogawa. Following its origin in the Ganges valley, devastating epidemics have occurred, often in association with large religious festivals, and pandemics have spread worldwide. The seventh pandemic, due to the El Tor biotype, began in 1961 and spread via the Middle East to become endemic in Africa, subsequently spreading throughout South and Central America. Numbers of cases of cholera have been increasing, with ongoing outbreaks in Yemen and Somalia. El Tor is more resistant to commonly used antimicrobials than classical *Vibrio*, and causes prolonged carriage in 5% of infections. An atypical serotype, O139, has been responsible for localised outbreaks in Bangladesh.

Infection spreads via the stools or vomit of symptomatic patients or of the much larger number of subclinical cases. Organisms survive for up to 2 weeks in fresh water and 8 weeks in saltwater. Transmission is normally through infected drinking water, shellfish and food contaminated by flies, or on the hands of carriers.

### Clinical features

Severe diarrhoea without pain or colic begins suddenly and is followed by vomiting. Following the evacuation of normal gut faecal contents, typical 'rice water' material is passed, consisting of clear fluid with flecks of mucus. Classical cholera produces enormous loss of fluid and electrolytes, leading to intense dehydration with muscular cramps. Shock and oliguria develop. Death from acute circulatory failure may occur rapidly unless fluid and electrolytes are replaced. Improvement is rapid with proper treatment.

The majority of infections, however, cause mild illness with slight diarrhoea. Occasionally, a very intense illness, 'cholera sicca', occurs, with loss of fluid into dilated bowel, killing the patient before typical gastrointestinal symptoms appear. The disease is more dangerous in children.

### Diagnosis and management

Clinical diagnosis is easy during an epidemic. Otherwise, the diagnosis should be confirmed bacteriologically. Stool dark-field microscopy shows the typical 'shooting star' motility of *V. cholerae*. Rectal swab or stool cultures allow identification. Cholera is notifiable under international health regulations.

Maintenance of circulation by replacement of water and electrolytes is paramount. Ringer's lactate is recommended for intravenous replacement. Vomiting usually stops once the patient is rehydrated, and fluid should then be given orally up to 500 mL hourly. Early intervention with oral rehydration solutions that include resistant starch, based on either rice or cereal, shortens the duration of diarrhoea and improves prognosis. Severe dehydration, as indicated by altered consciousness, skin tenting, very dry tongue, decreased pulses, low blood pressure or minimal urine output, mandates intravenous replacement. Total fluid requirements may exceed 50 L over a period of 2–5 days. Accurate records are greatly facilitated by the use of a 'cholera cot', which has a reinforced hole under the patient's buttocks, beneath which a graded bucket is placed.

Three days' treatment with tetracycline 250 mg 4 times daily, a single dose of doxycycline 300 mg or ciprofloxacin 1 g in adults reduces the duration of excretion of *V. cholerae* and the total volume of fluid needed for replacement.

### Prevention

Strict personal hygiene is vital and drinking water should come from a clean piped supply or be boiled. Flies must be denied access to food. Oral vaccines containing killed *V. cholerae* with or without the B subunit of cholera toxin are used in outbreaks and in long-term control strategies.

In epidemics, improvements in sanitation and access to clean water, public education and control of population movement are vital. Mass single-dose vaccination and tetracycline treatment are valuable control measures. Disinfection of discharges and soiled clothing, and scrupulous handwashing by medical attendants reduce spread.

## *Vibrio parahaemolyticus* infection

This marine organism produces a disease similar to enterotoxigenic *E. coli* (see above). It is very common where ingestion of raw seafood is widespread (e.g. Japan). After an incubation period of approximately 20 hours, explosive diarrhoea, abdominal cramps and vomiting occur. Systemic symptoms of headache and fever are frequent but the illness is self-limiting after 4–7 days. Rarely, a severe septic illness arises; in this case, *V. parahaemolyticus* can be isolated using specific halophilic culture.

## Bacillary dysentery (shigellosis)

Shigellae are Gram-negative rods, closely related to *E. coli*, that invade the colonic mucosa. There are four main groups: *Sh. dysenteriae*, *flexneri*, *boydii* and *sonnei*. In tropical regions bacillary dysentery is usually caused by *Sh. flexneri*, while in the UK most cases are caused by *Sh. sonnei*. Shigellae are often resistant to multiple antibiotics, especially in tropical countries. The organism only infects humans and its spread is facilitated by a low infecting dose of around 10 organisms.

Spread may occur via contaminated food or flies, but person-to-person transmission by unwashed hands after defaecation is the most important factor. Outbreaks occur in psychiatric hospitals, residential schools and other closed institutions, and dysentery is a constant accompaniment of wars and natural catastrophes, due to overcrowding and poor sanitation. *Shigella* infection may spread rapidly among men who have sex with men.

### Clinical features

Disease severity varies from mild *Sh. sonnei* infections that escape detection to more severe *Sh. flexneri* infections, while those due to *Sh. dysenteriae* may be fulminating and cause death within 48 hours.

In a moderately severe illness, the patient complains of diarrhoea, colicky abdominal pain and tenesmus. Stools are small, and after a few evacuations contain blood and purulent exudate with little faecal material. Fever, dehydration and weakness occur, with tenderness over the colon. Reactive arthritis or iritis occasionally complicate bacillary dysentery (p. 1035).

### Management and prevention

Oral rehydration therapy or, if diarrhoea is severe, intravenous fluid replacement is necessary. Antibiotic therapy is with ciprofloxacin (500 mg twice daily for 3 days). Azithromycin and ceftriaxone are alternatives but resistance occurs to all agents, especially in Asia. The use of antidiarrhoeal medication should be avoided.

The prevention of faecal contamination of food and milk and the isolation of cases may be difficult, except in limited outbreaks. Handwashing is essential.

## Respiratory bacterial infections

Most of these infections are described in [Chapter 17](#).

## Diphtheria

Infection with *Corynebacterium diphtheriae* occurs most commonly in the upper respiratory tract and is usually spread by droplet infection. Infection may also complicate skin lesions, especially in alcoholics. The organisms remain localised at the site of infection but release of a soluble exotoxin damages the heart muscle and the nervous system.

Diphtheria has been eradicated from many parts of the world by mass vaccination using a modified exotoxin but remains important in areas where vaccination is incomplete, e.g. in Russia and South-east Asia. The disease is notifiable in all countries of Europe and North America, and international guidelines have been issued by the WHO for the management of infection.

### Clinical features

The incubation period averages 2–4 days. The disease begins insidiously with a sore throat (Box 13.46). Despite modest fever, there is usually marked tachycardia. The diagnostic feature is the ‘wash-leather’ elevated, greyish-green membrane on the tonsils. It has a well-defined edge, is firm and adherent, and is surrounded by a zone of inflammation. There may be swelling of the neck (‘bull neck’) and tender enlargement of the lymph nodes. In the mildest infections, especially where there is a high degree of immunity, a membrane may not appear and inflammation is minimal.

With anterior nasal infection there is nasal discharge, frequently blood-stained. In laryngeal diphtheria, a husky voice and high-pitched cough signal potential respiratory obstruction requiring urgent tracheostomy. If infection spreads to the uvula, fauces and nasopharynx, the patient is gravely ill.

Death from acute circulatory failure may occur within the first 10 days. Late complications arise as a result of toxin action on the heart or nervous system. About 25% of survivors of the early toxæmia may later develop myocarditis with arrhythmias or cardiac failure. These are usually reversible, with no permanent damage other than heart block in survivors.

Neurological involvement occurs in 75% of cases. After tonsillar or pharyngeal diphtheria, it usually starts after 10 days with palatal palsy. Paralysis of accommodation often follows, manifest by difficulty in reading small print. Generalised polyneuritis with weakness and paraesthesia may follow in the next 10–14 days. Recovery from such neuritis is always ultimately complete.

### Management

A clinical diagnosis of diphtheria must be notified to the public health authorities and the patient sent urgently to a specialist infectious diseases unit. Empirical treatment should commence after collection of appropriate swabs.

Diphtheria antitoxin is produced from hyperimmune horse serum. It neutralises circulating toxin but not toxin already fixed to tissues, so it must be injected intramuscularly without awaiting the result of a throat swab. However, reactions to this foreign protein include a potentially lethal immediate anaphylactic reaction and a ‘serum sickness’ with fever, urticaria and joint pains, which occurs 7–12 days after injection. A careful history of previous horse serum injections or allergic reactions should be taken and a small test injection of serum should be given half an hour before the full dose in every patient. Epinephrine (adrenaline) solution must be available to treat any immediate type of reaction (0.5–1.0 mL of 1/1000 solution intramuscularly). An antihistamine is also given. In a severely ill patient, the risk of anaphylactic shock is outweighed by the mortal danger of diphtheritic toxæmia. A dose of up to 100 000 IU of antitoxin is injected intravenously if the test dose is tolerated. For disease of moderate severity, 16 000–40 000 IU intramuscularly will suffice, and for mild cases 4000–8000 IU.

#### 13.46 Clinical features of diphtheria

##### Acute infection

- Membranous tonsillitis
- or Nasal infection
- or Laryngeal infection
- or Skin/wound/conjunctival infection (rare)

##### Complications

- Laryngeal obstruction or paralysis
- Myocarditis
- Peripheral neuropathy

Penicillin (1200 mg 4 times daily IV) or amoxicillin (500 mg 3 times daily) should be administered for 2 weeks to eliminate *C. diphtheriae*. Patients allergic to penicillin can be given erythromycin. Due to poor immunogenicity of primary infection, all sufferers should be immunised with diphtheria toxoid following recovery.

Patients must be managed in strict isolation and attended by staff with a clearly documented immunisation history until three swabs 24 hours apart are culture-negative.

### Prevention

Active immunisation is recommended for all children. If diphtheria occurs in a closed community, contacts should be given erythromycin, which is more effective than penicillin in eradicating carriage.

All contacts should also be immunised or given a booster dose of toxoid. Booster doses are required every 10 years to maintain immunity.

## Pneumococcal infection

*Streptococcus pneumoniae* (the pneumococcus) is the leading cause of community-acquired pneumonia globally and one of the leading causes of infection-related mortality. Otitis media, meningitis and sinusitis are also frequently caused by *Strep. pneumoniae*. Occasional patients present with bacteraemia without obvious focus. Asplenic individuals are at risk of fulminant pneumococcal disease with purpuric rash.

Increasing rates of penicillin resistance have been reported around the world for *Strep. pneumoniae*, although they remain low in the UK. Strains with cephalosporin resistance causing meningitis require treatment with a combination of cephalosporins, glycopeptides and rifampicin. Macrolide resistance is also increasing. Newer quinolones are also used (e.g. levofloxacin and moxifloxacin) but rates of resistance are rising.

Vaccination of infants with the protein conjugate pneumococcal vaccine decreases *Strep. pneumoniae* infection in infants and in their relatives. The polysaccharide pneumococcal vaccine is used in individuals predisposed to *Strep. pneumoniae* infection and older people, but only modestly reduces pneumococcal bacteraemia and does not prevent pneumonia. All asplenic individuals should receive vaccination against *Strep. pneumoniae*.

## Anthrax

Anthrax is an endemic zoonosis in many countries; it causes human disease following inoculation of the spores of *Bacillus anthracis*. *B. anthracis* was the first bacterial pathogen described by Koch and the model pathogen for ‘Koch’s postulates’ (see Box 6.1). It is a Gram-positive organism with a central spore. The spores can survive for years in soil. Infection is commonly acquired from contact with animals, particularly herbivores. The ease of production of *B. anthracis* spores makes this infection a candidate for biological warfare or bioterrorism. *B. anthracis* produces a number of toxins that mediate the clinical features of disease.

### Clinical features

These depend on the route of entry of the anthrax spores.

#### Cutaneous anthrax

This skin lesion is associated with occupational exposure to anthrax spores during processing of hides and bone products. It accounts for the majority of clinical cases. Animal infection is a serious problem in Africa, India, Pakistan and the Middle East.

Spores are inoculated into exposed skin. A single lesion develops as an irritable papule on an oedematous haemorrhagic base. This progresses to a depressed black eschar. Despite extensive oedema, pain is infrequent.

#### Gastrointestinal anthrax

This is associated with the ingestion of contaminated meat. The caecum becomes infected, which produces nausea, vomiting, anorexia and fever, followed in 2–3 days by severe abdominal pain and bloody diarrhoea. Toxaemia and death can develop rapidly thereafter.

### Inhalational anthrax

Inhalational anthrax is extremely rare but has been associated with bioterrorism. Without rapid and aggressive therapy at the onset of symptoms, the mortality is 50%–90%. Fever, dyspnoea, cough, headache and sepsis develop 3–14 days following exposure. Typically, the chest X-ray shows only widening of the mediastinum and pleural effusions, which are haemorrhagic. Meningitis may occur.

### Management

*B. anthracis* can be cultured from skin swabs from lesions. Skin lesions are readily curable with early antibiotic therapy. Treatment is with ciprofloxacin (500 mg twice daily) until penicillin susceptibility is confirmed; the regimen can then be changed to benzylpenicillin with doses up to 2.4 g IV given 6 times daily or phenoxymethylpenicillin orally 500–1000 mg 4 times daily administered for 10 days. The addition of an aminoglycoside may improve the outlook in severe disease. In view of concerns about concomitant inhalational exposure, particularly in the era of bioterrorism, a further 2-month course of ciprofloxacin 500 mg twice daily or doxycycline 100 mg twice daily orally is added to eradicate inhaled spores. Inhalational anthrax is treated with ciprofloxacin and clindamycin for at least 14 days, followed by therapy to eradicate spores. Monoclonal antibodies against *B. anthracis* protective antigen can be added for systemic infection. Prophylaxis with ciprofloxacin (500 mg twice daily for 2 months) is recommended for anyone at high risk of inhalational exposure to anthrax spores and is combined with three doses of anthrax vaccine adsorbed (AVA).

## Bacterial infections with neurological involvement

Infections affecting the CNS, including bacterial meningitis, botulism and tetanus, are described on page 1171.

## Mycobacterial infections

### Tuberculosis

Tuberculosis is predominantly, although by no means exclusively, a respiratory disease and is described in Chapter 17.

### Leprosy

Leprosy (Hansen's disease) is a chronic granulomatous disease affecting skin and nerves and caused by *Mycobacterium leprae*, a slow-growing mycobacterium that cannot be cultured *in vitro*. The clinical manifestations are determined by the degree of the patient's cell-mediated immunity (CMI) towards *M. leprae* (Fig. 13.31). High levels of CMI with elimination of leprosy bacilli produces tuberculoid leprosy, whereas absent CMI results in lepromatous leprosy. Complications arise due to nerve damage, immunological reactions and bacillary infiltration. People with leprosy are frequently stigmatised and using the word 'leper' is inappropriate.

### Epidemiology and transmission

The WHO estimates there are around 200 000 new cases detected annually. About 70% of the world's leprosy patients live in India, with the disease endemic in Brazil, Indonesia, Mozambique, Madagascar, Tanzania and Nepal.

Untreated lepromatous patients discharge bacilli from the nose. Infection occurs through the nose, followed by haematogenous spread to skin and nerve. The incubation period is 2–5 years for tuberculoid cases and 8–12 years for lepromatous cases. Leprosy incidence peaks at 10–14 years, and is more common in males and in household contacts of leprosy cases.

### Pathogenesis

*M. leprae* has tropism for Schwann cells and skin macrophages. In tuberculoid leprosy, effective CMI controls bacillary multiplication

**Fig. 13.31** Leprosy: mechanisms of damage and tissue affected. Mechanisms under the broken line are characteristic of disease near the lepromatous end of the spectrum, and those under the solid line are characteristic of the tuberculoid end. They overlap in the centre where, in addition, instability predisposes to type 1 lepra reactions. At the peak in the centre, neither bacillary growth nor cell-mediated immunity has the upper hand. (BL = borderline lepromatous; BT = borderline tuberculoid; LL = lepromatous leprosy; TT = tuberculoid leprosy) Adapted from Bryceson ADM, Pfaltzgraff RE. *Leprosy*, 3rd edn. Churchill Livingstone, Elsevier Ltd; 1990.

(‘paucibacillary’) and organised epithelioid granulomata form. In lepromatous leprosy, there is abundant bacillary multiplication (‘multibacillary’), e.g. in Schwann cells and perineurium. Between these two extremes is a continuum, varying from patients with moderate CMI (borderline tuberculoid) to patients with little cellular response (borderline lepromatous).

Immunological reactions evolve as the immune response develops and the bacillary antigenic stimulus varies, particularly in borderline patients. Delayed hypersensitivity reactions produce type 1 (reversal) reactions, while immune complexes contribute to type 2 (erythema nodosum leprosum) reactions.

HIV/leprosy co-infected patients have typical lepromatous and tuberculoid leprosy skin lesions and typical leprosy histology and granuloma formation. Surprisingly, even with low circulating CD4 counts, tuberculoid leprosy may be observed and there is not an obvious shift to lepromatous leprosy.

### Clinical features

Box 13.47 gives the cardinal features of leprosy. Types of leprosy are compared in Box 13.48.

- **Skin.** The most common skin lesions are macules or plaques. Tuberculoid patients have few, hypopigmented lesions (Fig. 13.32A). In lepromatous leprosy, papules, nodules or diffuse infiltration of the skin occur. The earliest lesions are ill defined; gradually, the skin becomes infiltrated and thickened. Facial skin thickening leads to the characteristic leonine facies (Fig. 13.32B).
- **Anaesthesia.** In skin lesions, the small dermal sensory and autonomic nerve fibres are damaged, causing localised sensory loss and loss of sweating. Anaesthesia can occur in the distribution of a damaged large peripheral nerve. A ‘glove and stocking’ sensory neuropathy is also common in lepromatous leprosy.
- **Nerve damage.** Peripheral nerve trunks are affected at ‘sites of predilection’. These are the ulnar (elbow), median (wrist), radial (humerus), radial cutaneous (wrist), common peroneal (knee), posterior tibial and sural nerves (ankle), facial nerve (zygomatic arch) and great auricular nerve (posterior triangle of the neck). Damage to peripheral nerve trunks produces characteristic signs with regional

### 13.47 Cardinal features of leprosy

- Skin lesions, typically anaesthetic at tuberculoid end of spectrum
- Thickened peripheral nerves
- Acid-fast bacilli on skin smears or biopsy

### 13.48 Clinical characteristics of the polar forms of leprosy

Clinical and tissue-specific features	Lepromatous	Tuberculoid
<b>Skin and nerves</b>		
Number and distribution	Widely disseminated	One or a few sites, asymmetrical
<b>Skin lesions</b>		
Definition:		
Clarity of margin	Poor	Good
Elevation of margin	Never	Common
Colour:		
Dark skin	Slight hypopigmentation	Marked hypopigmentation
Light skin	Slight erythema	Coppery or red
Surface	Smooth, shiny	Dry, scaly
Central healing	None	Common
Sweat and hair growth	Impaired late	Impaired early
Loss of sensation	Late	Early and marked
<b>Nerve enlargement and damage</b>	Late	Early and marked
<b>Bacilli (bacterial index)</b>	Many (5 or 6+)	Absent (0)
<b>Natural history</b>	Progressive	Self-healing
<b>Other tissues</b>	Upper respiratory mucosa, eye, testes, bones, muscle	None
<b>Reactions</b>	Immune complexes (type 2)	Cell-mediated (type 1)

sensory loss and muscle dysfunction (Fig. 13.32C). All these nerves should be examined for enlargement and tenderness, and tested for motor and sensory function. The CNS is not affected.

- *Eye involvement.* Blindness is a devastating complication for a patient with anaesthetic hands and feet. Eyelid closure is impaired when the facial nerve is affected. Damage to the trigeminal nerve causes anaesthesia of the cornea and conjunctiva. The cornea is then susceptible to trauma and ulceration.
- *Other features.* Many organs can be affected. Nasal collapse occurs secondary to bacillary destruction of the nasal cartilage and bone. Diffuse infiltration of the testes causes testicular atrophy and the acute orchitis that occurs with type 2 reactions. This results in azoospermia and hypogonadism.

#### Leprosy reactions

Leprosy reactions (Box 13.49) are events superimposed on the cardinal features shown in Box 13.47.

- *Type 1 (reversal) reactions.* These occur in 30% of borderline patients (BT, BB or BL – see below) and are delayed hypersensitivity reactions. Skin lesions become erythematous (Fig. 13.32D). Peripheral nerves become tender and painful, with sudden loss of nerve function. These reactions may occur spontaneously, after starting treatment and also after completion of multidrug therapy (MDT).
- *Type 2 (erythema nodosum leprosum, ENL) reactions.* These are partly due to immune complex deposition and occur in BL and LL

patients who produce antibodies and have a high antigen load. They manifest with malaise, fever and crops of small pink nodules on the face and limbs. Iritis and episcleritis are common. Other signs are acute neuritis, lymphadenitis, orchitis, bone pain, dacrylitis, arthritis and proteinuria. ENL may continue intermittently for several years.

#### Borderline cases

In borderline tuberculoid (BT) cases, skin lesions are more numerous than in tuberculoid (TT) cases, and there is more severe nerve damage and a risk of type 1 reactions. In borderline leprosy (BB) cases, skin lesions are numerous and vary in size, shape and distribution; annular lesions are characteristic and nerve damage is variable. In borderline lepromatous (BL) cases, there are widespread small macules in the skin and widespread nerve involvement; both type 1 and type 2 reactions occur.

Pure neural leprosy (i.e. without skin lesions) occurs principally in India and accounts for 10% of patients. There is asymmetrical involvement of peripheral nerve trunks and no visible skin lesions. On nerve biopsy, all types of leprosy have been found.

#### Investigations

The diagnosis is clinical, made by finding a cardinal sign of leprosy and supported by detecting acid-fast bacilli in slit-skin smears or typical histology in a skin biopsy. Slit-skin smears are obtained by scraping dermal material on to a glass slide. The smears are then stained for acid-fast bacilli, the number counted per high-power field and a score derived on a logarithmic scale (0–6): the bacterial index (BI). Smears are useful for confirming the diagnosis and monitoring response to treatment. Neither serology nor PCR is sensitive or specific enough for diagnosis.

#### Management

The principles of treatment are outlined in Box 13.50. All leprosy patients require MDT with an approved first-line regimen (Box 13.51).

Rifampicin is a potent bactericidal for *M. leprae* but should always be given in combination with other antileprotics, since a single-step mutation can confer resistance. Dapsone is bacteriostatic. It commonly causes mild haemolysis and rarely anaemia. Clofazimine is a red, fat-soluble crystalline dye, weakly bactericidal for *M. leprae*. Skin discoloration (red to purple–black) and ichthyosis are troublesome side-effects, particularly on pale skins. New bactericidal drugs against *M. leprae* have been identified, notably fluoroquinolones (e.g. ofloxacin). Minocycline and clarithromycin may also be used. These agents are second-line drugs. Minocycline causes grey pigmentation of skin lesions.

Single-dose combination treatment (rifampicin ofloxacin and minocycline) is less effective than the conventional 6-month treatment for paucibacillary leprosy and has fallen out of favour.

Lepra reactions are treated as shown in Box 13.49. Chloroquine can also be used.

#### Patient education

Patient education emphasises that, after 3 days of chemotherapy, they are not infectious, that gross deformities are not inevitable and that they can lead a normal social life.

Patients with anaesthetic hands or feet need to avoid and treat burns or other minor injuries. Good footwear is important. Physiotherapy helps maintain range of movement of affected muscles and neighbouring joints.

#### Prognosis

Untreated, tuberculoid leprosy has a good prognosis; it may self-heal and peripheral nerve damage is limited. Lepromatous leprosy (LL) is a progressive condition with high morbidity if untreated.

After treatment, the majority of patients, especially those who have no nerve damage at the time of diagnosis, do well, with resolution of skin lesions. Borderline patients are at risk of developing type 1 reactions, which may result in devastating nerve damage.

**Fig. 13.32 Clinical features of leprosy.** **A** Tuberculoid leprosy. Single lesion with a well-defined active edge and anaesthesia within the lesion. **B** Lepromatous leprosy. Widespread nodules and infiltration, with loss of the eyebrows. This man also has early collapse of the nose. **C** Borderline tuberculoid leprosy with severe nerve damage. This boy has several well-defined, hypopigmented, macular, anaesthetic lesions. He has severe nerve damage affecting both ulnar and median nerves bilaterally and has sustained severe burns to his hands. **D** Reversal (type 1) reactions. Erythematous, oedematous lesions.

13.49 Reactions in leprosy		
	Lepra reaction type 1 (reversal)	Lepra reaction type 2 (erythema nodosum leprosum)
<b>Mechanism</b>	Cell-mediated hypersensitivity	Immune complexes
<b>Clinical features</b>	Painful tender nerves, loss of function Swollen skin lesions New skin lesions	Tender papules and nodules; may ulcerate Painful tender nerves, loss of function Iritis, orchitis, myositis, lymphadenitis Fever, oedema
<b>Management</b>	Prednisolone 40 mg, reducing over 3–6 months <sup>1</sup>	Moderate: prednisolone 40 mg daily Severe: thalidomide <sup>2</sup> or prednisolone 40–80 mg daily, reducing over 1–6 months; local if eye involved <sup>3</sup>
<sup>1</sup> Indicated for any new impairment of nerve or eye function. <sup>2</sup> Contraindicated in women who may become pregnant. <sup>3</sup> 1% hydrocortisone drops or ointment and 1% atropine drops.		

13.50 Principles of leprosy treatment	
•	Stop the infection with chemotherapy
•	Treat reactions
•	Educate the patient about leprosy
•	Prevent disability
•	Support the patient socially and psychologically

### Prevention and control

The previous strategy of centralised leprosy control campaigns has been superseded by integrated programmes, with primary health-care workers in many countries now responsible for case detection and provision of MDT. It is not yet clear how successful this will be, especially in the time-consuming area of disability prevention.

BCG vaccination offers protection against leprosy; adding killed *M. leprae* to BCG does not further enhance protection.

## Rickettsial and related intracellular bacterial infections

### Rickettsial fevers

The rickettsial fevers are the most common tick-borne infections. It is important to ask potentially infected patients about contact with ticks, lice or fleas. There are two main groups of rickettsial fevers: spotted fevers and typhus (Box 13.52).

### Pathogenesis

The rickettsiae are intracellular Gram-negative organisms that parasitise the intestinal canal of arthropods. Infection of humans through the skin occurs from the excreta of arthropods, but the saliva of some biting vectors is infected. The organisms multiply in capillary endothelial cells, producing lesions in the skin, CNS, heart, lungs, liver, kidneys and skeletal muscles. Endothelial proliferation, associated with a perivascular reaction, may cause thrombosis and purpura. In epidemic typhus, the brain is the target organ; in scrub typhus, the cardiovascular system and lungs in particular are attacked. An eschar, a black necrotic crusted sore, is often found in tick- and mite-borne typhus (see Fig. 13.8C). This is due to vasculitis following immunological recognition of the inoculated organism. Regional lymph nodes often enlarge.

## Spotted fever group

### Rocky Mountain spotted fever

*Rickettsia rickettsii* is transmitted by tick bites. It is widely distributed and increasing in western and south-eastern states of the USA and also in Central and South America. The incubation period is about 7 days. The

rash appears on about the third or fourth day of illness, looking at first like measles, but in a few hours a typical maculopapular eruption develops. The rash spreads in 24–48 hours from wrists, forearms and ankles to the back, limbs and chest, and then to the abdomen, where it is least pronounced. Larger cutaneous and subcutaneous haemorrhages may appear in severe cases. The liver and spleen become palpable. At the extremes of life, the mortality is 2%–12%.

### Other spotted fevers

*R. conorii* (boutonnoise fever) causes Mediterranean spotted fever, which extends to Africa and India, while *R. africae* (African tick bite fever) causes African tick typhus. The incubation period is approximately 7 days. Infected tick bites result from walking on grasslands or are acquired from pet dogs. Examination may reveal a diagnostic eschar, and the maculopapular rash on the trunk, limbs, palms and soles. There may be delirium and meningeal signs in severe infections, but recovery is usual. *R. africae* may cause multiple eschars. Some cases, particularly those with *R. africae*, present without rash ('spotless spotted fever'). Other spotted fevers are shown in [Box 13.52](#).

## Typhus group

### Scrub typhus fever

Scrub typhus is caused by *Orientia tsutsugamushi*, transmitted by mites. It occurs in the Far East, Myanmar, Pakistan, Bangladesh, India, Indonesia, the South Pacific islands and Queensland, particularly where patches of forest cleared for plantations have attracted rats and mites.

In many patients, one or more eschars develop, surrounded by cellulitis (see [Fig. 13.8C](#)), with regional lymph node enlargement. The incubation period is about 9 days.

Mild or subclinical cases are common. The onset of symptoms is usually sudden, with headache (often retro-orbital), fever, malaise, weakness and cough. In severe illness, the general symptoms increase, with apathy and prostration. An erythematous maculopapular rash often appears on about the 5th–7th day and spreads to the trunk, face and limbs, including the palms and soles, with generalised painless lymphadenopathy. The

13.51 World Health Organization 2018 guidelines for multidrug therapy (MDT) regimens in leprosy			
Type of leprosy <sup>1</sup>	Monthly supervised treatment	Daily self-administered treatment	Duration of treatment
Paucibacillary	Rifampicin 600 mg	Dapsone 100 mg	6 months
	Clofazimine 300 mg	Clofazimine 50 mg	
Multibacillary	Rifampicin 600 mg	Dapsone 100 mg	12 months
	Clofazimine 300 mg	Clofazimine 50 mg	
Rifampicin resistant		Clofazimine 50 mg plus two second-line agents <sup>2</sup> ×6 months, then plus one second line ×18 month	24 months

<sup>1</sup>Classification uses the number of skin lesions: paucibacillary (1–5 skin lesions); multibacillary (>5 skin lesions, nerve involvement or positive slit-skin smear). <sup>2</sup>Second-line agents minocycline 100 mg, clarithromycin 500 mg, or a fluoroquinolone (e.g. ofloxacin 400 mg, levofloxacin 500 mg or moxifloxacin 400 mg) but only use a fluoroquinolone if TB excluded and no fluoroquinolone resistance.

13.52 Features of rickettsial infections								
Disease	Organism	Reservoir	Vector	Geographical area	Rash	Gangrene	Target organs	Mortality
<b>Spotted fever group</b>								
Rocky Mountain spotted fever	<i>R. rickettsii</i>	Rodents, dogs, ticks	<i>Ixodes</i> tick	North, Central and South America	Morbilloform Haemorrhagic	Often	Bronchi, myocardium, brain, skin	2%–12% <sup>2</sup>
Boutonnoise fever	<i>R. conorii</i>	Rodents, dogs, ticks	<i>Ixodes</i> tick	Mediterranean, Africa, South-west Asia, India	Maculopapular	–	Skin, meninges	2.5% <sup>3</sup>
Siberian tick typhus	<i>R. sibirica</i>	Rodents, birds, domestic animals, ticks	Various ticks	Siberia, Mongolia, northern China	Maculopapular	–	Skin, meninges	Rare <sup>3</sup>
Australian tick typhus	<i>R. australis</i>	Rodents, ticks	Ticks	Australia	Maculopapular	–	Skin, meninges	Rare <sup>3</sup>
Oriental spotted fever	<i>R. japonica</i>	Rodents, dogs, ticks	Ticks	Japan	Maculopapular	–	Skin, meninges	Rare <sup>3</sup>
African tick bite fever <sup>1</sup>	<i>R. africae</i>	Cattle, game, ticks	<i>Ixodes</i> tick	South Africa	Can be spotless	–	Skin, meninges	Rare <sup>3</sup>
<b>Typhus group</b>								
Scrub typhus	<i>Orientia tsutsugamushi</i>	Rodents	<i>Trombicula</i> mite	South-east Asia	Maculopapular	Unusual	Bronchi, myocardium, brain, skin	Rare <sup>3</sup>
Epidemic typhus	<i>R. prowazekii</i>	Humans	Louse	Worldwide	Morbilloform Haemorrhagic	Often	Brain, skin, bronchi, myocardium	Up to 40%
Endemic typhus	<i>R. typhi</i>	Rats	Flea	Worldwide	Slight	–	–	Rare <sup>3</sup>

<sup>1</sup>Eschar at bite site and local lymphadenopathy. <sup>2</sup>Highest in adult males. <sup>3</sup>Except in infants, older people and the debilitated.

rash fades by the 14th day. The temperature rises rapidly and continues as a remittent fever (i.e. the difference between maximum and minimum temperature exceeds 1°C), remaining above normal with sweating until it falls on the 12th–18th day. In severe infection, the patient is prostrate with cough, pneumonia, delirium and deafness. Cardiac failure, renal failure and haemorrhage may develop. Convalescence is often slow and tachycardia may persist for some weeks.

### Epidemic (louse-borne) typhus

Epidemic typhus is caused by *R. prowazekii* and is transmitted by infected faeces of the human body louse, usually through scratching the skin. Patients with epidemic typhus infect lice, which leave when the patient is febrile. In conditions of overcrowding, the disease spreads rapidly. It is prevalent in parts of Africa, especially Ethiopia and Rwanda, and in the South American Andes and Afghanistan. Large epidemics have occurred in Europe, usually during wars. The incubation period is usually 12–14 days.

There may be several days of malaise but the onset is more often sudden, with rigors, fever, frontal headaches, pains in the back and limbs, constipation and bronchitis. The face is flushed and cyanotic, the eyes are congested and the patient becomes confused. The rash appears on the 4th–6th day. In its early stages, it disappears on pressure but soon becomes petechial with subcutaneous mottling. The rash appears first on the anterior folds of the axillae, sides of the abdomen or backs of the hands, then on the trunk and forearms. The neck and face are seldom affected. During the second week, symptoms increase in severity. Sores develop on the lips. The tongue becomes dry, brown, shrunken and tremulous. The spleen is palpable, the pulse feeble and the patient stuporous and delirious. The temperature falls rapidly at the end of the second week and the patient recovers gradually. In fatal cases, the patient usually dies in the second week from toxæmia, cardiac or renal failure, or pneumonia.

### Endemic (flea-borne) typhus

Flea-borne or 'endemic' typhus caused by *R. typhi* is endemic worldwide. Humans are infected when the faeces or contents of a crushed flea, which has fed on an infected rat, are introduced into the skin. The incubation period is 8–14 days. The symptoms resemble those of a mild louse-borne typhus. The rash may be scanty and transient.

### Investigation of rickettsial infection

Routine blood investigations are not diagnostic. There is usually hepatitis and thrombocytopenia. Diagnosis is made on clinical grounds and response to treatment, and may be confirmed by antibody detection or PCR in specialised laboratories. Differential diagnoses include malaria, typhoid, meningococcal sepsis and leptospirosis.

### Management of rickettsial fevers

The rickettsial fevers vary in severity but all respond to tetracycline 500mg 4 times daily, doxycycline 200mg daily or chloramphenicol 500mg 4 times daily for 7 days. Louse-borne typhus and scrub typhus can be treated with a single dose of 200mg doxycycline, repeated for 2–3 days to prevent relapse. Chloramphenicol- and doxycycline-resistant strains of *O. tsutsugamushi* have been reported from Thailand and patients here may need treatment with rifampicin.

Nursing care is important, especially in epidemic typhus. Sedation may be required for delirium and blood transfusion for haemorrhage. Relapsing fever and typhoid are common intercurrent infections in epidemic typhus, and pneumonia in scrub typhus. Convalescence is usually protracted, especially in older people.

To prevent rickettsial infection, lice, fleas, ticks and mites need to be controlled with insecticides.

## Q fever

Q fever occurs worldwide and is caused by the rickettsia-like organism *Coxiella burnetii*, an obligate intracellular organism that survives in the extracellular environment. Cattle, sheep and goats are important reservoirs and the organism is transmitted by inhalation of aerosolised particles.

*C. burnetii* exhibits phase variation, due to antigenic variation resulting from changes to its lipopolysaccharide (LPS). When isolated from animals or humans, *C. burnetii* expresses phase I antigen and is very infectious (a single bacterium is sufficient to infect a human). In culture, there is an antigenic shift to the phase II form, which is not infectious. Measurement of antigenic shift helps differentiate acute and chronic Q fever.

### Clinical features

The incubation period is 3–4 weeks. The initial symptoms are non-specific with fever, headache and chills; in 20% of cases, a maculopapular rash occurs. Other presentations include pneumonia and hepatitis. Chronic Q fever may present with osteomyelitis, encephalitis and endocarditis.

### Investigations and management

Diagnosis is usually serological and the stage of the infection can be distinguished by isotype tests and phase-specific antigens. Phase I and II IgM titres peak at 4–6 weeks. In chronic infections, IgG titres to phase I and II antigens may be raised. Suspected tissue infection (e.g. endocarditis) can be diagnosed by detection of specific DNA (PCR).

Prompt treatment of acute Q fever with doxycycline reduces fever duration. Treatment of Q fever endocarditis is problematic, requiring prolonged therapy with doxycycline and rifampicin or ciprofloxacin with hydroxychloroquine; even then, organisms are not always eradicated. Valve surgery is often required.

## Bartonellosis

Bartonellae are intracellular Gram-negative bacilli closely related to the rickettsiae, which are important causes of 'culture-negative' endocarditis. They are found in many domestic pets, such as cats, although for several the host is undefined (Box 13.53). The principal human pathogens are *Bartonella quintana*, *B. henselae* and *B. bacilliformis*. *Bartonella* infections are associated with the following:

- *Trench fever*. This is a relapsing fever with severe leg pain and is caused by *B. quintana*. The disease is not fatal but is very debilitating.
- *Bacteraemia and endocarditis in the homeless*. Endocarditis due to *B. quintana* or *B. henselae* is associated with severe damage to the heart valves.
- *Cat scratch disease*. *B. henselae* causes this common benign lymphadenopathy in children and young adults. A vesicle or papule develops on the head, neck or arms after a cat scratch. The lesion resolves spontaneously but there may be regional lymphadenopathy that persists for up to 4 months before also resolving spontaneously. Rare complications include retinitis and encephalopathy.
- *Bacillary angiomatosis*. This is an HIV-associated disease caused by *B. quintana* or *B. henselae* (see p. 358).
- *Oroya fever and verruga peruana (Carrion's disease)*. This is endemic in areas of Peru. It is a biphasic disease caused by *B. bacilliformis*, transmitted by sandflies of the genus *Phlebotomus*. Fever, haemolytic anaemia and microvascular thrombosis with end-organ ischaemia are features. It is frequently fatal if untreated.

### 13.53 Clinical diseases caused by *Bartonella* spp.

Reservoir	Vector	Organism	Disease
Cats	Flea	<i>B. henselae</i>	Cat scratch disease, bacillary angiomatosis, endocarditis
Undefined	Lice	<i>B. quintana</i>	Trench fever, bacillary angiomatosis, endocarditis
Undefined	Sandfly	<i>B. bacilliformis</i>	Carrion's disease: Oroya fever and verruga peruana
Undefined	Flea	<i>B. rochalimae</i>	Fever, rash, anaemia, splenomegaly

### Investigations and management

Bartonellae can be cultured in specialised laboratories but PCR is often used to diagnose infection. Serum antibody detection is possible but cross-reactions occur with *Chlamydia* and *Coxiella* spp.

*Bartonella* spp. are typically treated with macrolides or tetracyclines. Antibiotic use is guided by clinical need. Cat scratch disease usually resolves spontaneously but *Bartonella* endocarditis requires valve replacement and combination antibiotic therapy with doxycycline and gentamicin.

## Chlamydial infections

These are listed in Box 13.54 and are also described on pages 379 and 512.

### Trachoma

Trachoma is a chronic keratoconjunctivitis caused by *Chlamydia trachomatis* and is the most common cause of avoidable blindness. The classic trachoma environment is dry and dirty, causing children to have eye and nose discharges. Transmission occurs through flies, on fingers and within families. In endemic areas, the disease is most common in children.

### Pathology and clinical features

The onset is usually insidious. Infection may be asymptomatic, last for years with prolonged latency and may recrudescence. The conjunctiva of the upper lid is first affected with vascularisation and cellular infiltration. Early symptoms include conjunctival irritation and blepharospasm. The early follicles are characteristic (Fig. 13.33) but clinical differentiation from conjunctivitis due to other causes may be difficult. Scarring causes inversion of the lids (entropion) so that the lashes rub against the cornea (trichiasis). The cornea becomes vascularised and opaque with detection only when vision begins to fail.

13.54 Chlamydial infections	
Organism	Disease caused
<i>Chlamydia trachomatis</i>	Trachoma Lymphogranuloma venereum (see Box 15.12) Cervicitis, urethritis, proctitis (see Ch. 15)
<i>Chlamydia psittaci</i>	Psittacosis (see Box 17.37)
<i>Chlamydophila (Chlamydia) pneumoniae</i>	Atypical pneumonia (see Box 17.37) Acute/chronic sinusitis

**Fig. 13.33 Trachoma.** Trachoma is characterised by hyperaemia and numerous pale follicles. Courtesy of Institute of Ophthalmology, Moorfields Eye Hospital, London.

### Investigations and management

Intracellular inclusions may be demonstrated in conjunctival scrapings by staining with iodine or immunofluorescence. Although chlamydiae may, in theory, be isolated in chick embryo or cell culture or detected by nucleic acid amplification tests, these methods are rarely available in the areas where trachoma is encountered, and in any case their sensitivity and specificity are poorly established. Diagnosis of trachoma is therefore based on clinical and epidemiological features.

A single dose of oral azithromycin (20mg/kg) is superior to 6 weeks of tetracycline eye ointment twice daily for individuals in mass treatment programmes. Deformity and scarring of the lids, and corneal opacities, ulceration and scarring require surgical treatment after control of local infection.

### Prevention

Personal and family hygiene should be improved. Proper care of the eyes of newborn and young children is essential. Family contacts should be examined. The WHO is promoting the SAFE strategy for trachoma control (surgery, antibiotics, facial cleanliness and environmental improvement).

## Protozoal infections

Protozoa are important causes of infectious diseases. They can be categorised according to whether they cause systemic or local infection. Trichomoniasis is described on page 374.

### Systemic protozoal infections

#### Malaria

Malaria in humans is caused by *Plasmodium falciparum*, *P. vivax*, *P. ovale* (subspecies *curtisi* and *walleri*), *P. malariae* and the zoonotic simian parasite *P. knowlesi*. It is transmitted by the bite of female *Anopheles* mosquitoes and occurs throughout the tropics and subtropics at altitudes below 1500 m (Fig. 13.34). The WHO estimates that 228 million cases of clinical malaria occurred in 2018, 93% of these in Africa, especially among children and pregnant women. The incidence rate of malaria declined globally between 2010 and 2018 due to WHO prevention and treatment campaigns. However, *P. falciparum* has now become resistant to artemisinins as well as chloroquine, mefloquine and sulfadoxine-pyrimethamine, initially in South-east Asia. The WHO is now planning for elimination of malaria in certain countries by utilising the 'best evidence' in bed nets, rapid diagnostic tests and artemisinin combination therapy (ACT).

Travellers are susceptible to malaria. Most cases are due to *P. falciparum*, usually from Africa, and of these 1% die because of late diagnosis. Migrants from endemic countries who spend long periods of time in non-endemic countries are particularly at risk if they visit friends and family in their country of origin. They have lost their partial immunity and frequently do not take malaria prophylaxis. A few people living near airports in Europe have acquired malaria from accidentally imported mosquitoes.

**Fig. 13.34 Distribution of malaria.** (For up-to-date information see the Malaria Atlas Project (MAP): [map.ox.ac.uk](http://map.ox.ac.uk).)

## Pathogenesis

### Life cycle of the malarial parasite

The female anopheline mosquito becomes infected when it feeds on human blood containing gametocytes, the sexual forms of the malarial parasite (Figs. 13.35 and 13.36). Development in the mosquito takes 7–20 days, and results in sporozoites accumulating in the salivary glands and being inoculated into the human blood stream. Sporozoites disappear from human blood within half an hour and enter the liver. After some days, merozoites leave the liver and invade red blood cells, where further asexual cycles of multiplication take place, producing schizonts. Rupture of the schizont releases more merozoites into the blood and causes fever, the periodicity of which depends on the species of parasite.

*P. vivax* and *P. ovale* may persist in liver cells as dormant forms, hypnozoites, capable of developing into merozoites months or years

**Fig. 13.35** Scanning electron micrograph of *Plasmodium falciparum* oocysts lining an anopheline mosquito's stomach.

**Fig. 13.36** Malarial parasites: life cycle. Hypnozoites (\*) are present only in *Plasmodium vivax* and *P. ovale* infections. (RBC = red blood cell)

later. Thus the first attack of clinical malaria may occur long after the patient has left the endemic area, and the disease may relapse after treatment with drugs that only kill the erythrocytic stage of the parasite.

*P. falciparum*, *P. knowlesi* and *P. malariae* have no persistent exo-erythrocytic phase but recrudescence of fever may result from multiplication of parasites in red cells that have not been eliminated by treatment and immune processes (Box 13.55).

### Pathology

Red cells infected with malaria undergo haemolysis. This is most severe with *P. falciparum*, which invades red cells of all ages; *P. vivax* and *P. ovale* preferentially invade younger cells, and *P. malariae* normoblasts, so that infections remain lower. Anaemia may be profound and is worsened by dyserythropoiesis, splenomegaly and depletion of folate stores.

In *P. falciparum* malaria, red cells containing trophozoites adhere to vascular endothelium in post-capillary venules in brain, kidney, liver, lungs and gut by the formation of 'knob' proteins. They also form 'rosettes' and rouleaux with uninfected red cells. Vessel congestion results in organ damage, which is exacerbated by rupture of schizonts, liberating toxic and antigenic substances (Fig. 13.36).

*P. falciparum* has influenced human evolution, with the appearance of protective mutations such as sickle-cell (Hb), thalassaemia, glucose-6-phosphate dehydrogenase (G6PD) deficiency (see Ch. 25) and HLA-B53. *P. falciparum* does not grow well in red cells that contain haemoglobin F, C or especially S. Haemoglobin S heterozygotes (AS) are protected against the lethal complications of malaria. *P. vivax* cannot enter red cells that lack the Duffy blood group; therefore many West Africans and African Americans are protected.

### Clinical features

The clinical features of malaria are non-specific and the diagnosis must be suspected in anyone returning from an endemic area who has features of infection.

*P. falciparum* infection

This is the most dangerous of the malarias. The onset is often insidious, with malaise, headache and vomiting. Cough and mild diarrhoea are also common. The fever has no particular pattern and the classic

periodicity is rarely observed. Jaundice is common due to haemolysis and hepatic dysfunction. The liver and spleen enlarge and may become tender. Anaemia develops rapidly, as does thrombocytopenia.

A patient with *falciparum* malaria, apparently not seriously ill, may rapidly develop dangerous complications (Fig. 13.37 and Box 13.56). Cerebral malaria is manifested by delirium, seizures or coma, usually without localising signs. Children die rapidly without any specific symptoms other than fever. Immunity is impaired in pregnancy and the parasite can preferentially bind to the placental protein chondroitin sulphate A. Abortion and intrauterine growth retardation from parasitisation of the maternal side of the placenta are frequent. Previous splenectomy increases the risk of severe malaria. Recurrent infection is rarely associated with later development of endemic Burkitt lymphoma and hyper-reactive (tropical) splenomegaly.

*P. vivax* and *P. ovale* infection

Illness usually starts with several days of continued fever before the development of classical bouts of fever on alternate days. Fever starts with a rigor. The patient feels cold and the temperature rises to about 40°C. After half an hour to an hour, the hot or flush phase begins. It lasts several hours and gives way to profuse perspiration and a gradual fall in temperature. The cycle is repeated 48 hours later. Gradually, the spleen and liver enlarge and may become tender. Anaemia develops slowly. Relapses are frequent in the first 2 years after leaving the malarious area and infection may be acquired from blood transfusion.

13.55 Relationships between life cycle of parasite and clinical features of malaria			
Cycle/feature	<i>Plasmodium vivax</i> , <i>P. ovale</i>	<i>P. malariae</i>	<i>P. falciparum</i>
Pre-patent period (minimum incubation)	8–25 days	15–30 days	8–25 days
Exo-erythrocytic cycle	Persistent as hypnozoites	Pre-erythrocytic only	Pre-erythrocytic only
Asexual cycle	48 hrs synchronous	72 hrs synchronous	<48 hrs asynchronous
Fever periodicity	Alternate days	Every third day	None
Delayed onset	Common	Rare	Rare
Relapses	Common up to 2 years	Recrudescence many years later	Recrudescence up to 1 year

### 13.56 Severe manifestations/complications of *falciparum* malaria and their immediate management

#### Coma (cerebral malaria)

- Maintain airway
- Nurse on side
- Exclude other treatable causes of coma (e.g. hypoglycaemia, bacterial meningitis)
- Avoid harmful ancillary treatments such as glucocorticoids, heparin and adrenaline (epinephrine)
- Intubate if necessary

#### Hyperpyrexia

- Tepid sponging, fanning, cooling blanket
- Antipyretic drug (paracetamol)

#### Convulsions

- Maintain airway
- Treat promptly with diazepam or paraldehyde injection

#### Hypoglycaemia

- Measure blood glucose
- Give 50% dextrose injection followed by 10% dextrose infusion (glucagon may be ineffective)

#### Severe anaemia (packed cell volume <15%)

- Transfuse fresh whole blood or packed cells if pathogen screening of donor blood is available

#### Acute pulmonary oedema

- Nurse at 45°, give oxygen, venesect 250 mL of blood, give diuretic, stop intravenous fluids
- Intubate and add PEEP/CPAP in life-threatening hypoxaemia
- Haemofilter

#### Acute kidney injury

- Exclude pre-renal causes
- Fluid resuscitation if appropriate
- Peritoneal dialysis (haemofiltration or haemodialysis if available)

#### Spontaneous bleeding and coagulopathy

- Transfuse screened fresh whole blood (cryoprecipitate/fresh frozen plasma and platelets if available)
- Vitamin K injection

#### Metabolic acidosis

- Exclude or treat hypoglycaemia, hypovolaemia and Gram-negative sepsis
- Fluid resuscitation
- Give oxygen

#### Shock ('algid malaria')

- Suspect Gram-negative sepsis
- Take blood cultures
- Give parenteral antimicrobials
- Correct haemodynamic disturbances

#### Aspiration pneumonia

- Give parenteral antimicrobial drugs
- Change position
- Physiotherapy
- Give oxygen

#### Hyperparasitaemia

- Consider exchange transfusion (e.g. >10% of circulating erythrocytes parasitised in non-immune patient with severe disease)

#### Specific therapy

- Intravenous artesunate
- Mefloquine should be avoided due to increased risk of post-malaria neurological syndrome

(CPAP = continuous positive airway pressure; PEEP = positive end-expiratory pressure)

From WHO. Severe *falciparum* malaria. In: Severe and complicated malaria, 3rd edn. Trans R Soc Trop Med Hyg 2000; 94 (suppl. 1):S1–41.

#### *P. malariae* and *P. knowlesi* infection

This is usually associated with mild symptoms and bouts of fever every third day. Parasitaemia may persist for many years, with the occasional recrudescence of fever or without producing any symptoms. Chronic *P. malariae* infection causes glomerulonephritis and long-term nephrotic syndrome in children. *P. knowlesi* is usually mild but can deteriorate rapidly.

#### Investigations

WHO recommends prompt malaria diagnosis, either by microscopy or malaria rapid diagnostic test (RDT), whenever malaria is suspected. In a Giemsa-stained thick film, erythrocytes are lysed, releasing all blood stages of the parasite. This, as well as the fact that more blood is used in thick films, facilitates the diagnosis of low-level parasitaemia. A thin film is essential to confirm the diagnosis, species and, in *P. falciparum* infections, to quantify the parasite load (by counting the percentage of infected erythrocytes). *P. falciparum* parasites may be very scanty, especially in patients who have been partially treated. With *P. falciparum*, only ring forms are normally seen in the early stages (see Fig. 13.37); with the other species, all stages of the erythrocytic cycle may be found. Gametocytes appear after about 2 weeks, persist after treatment and are harmless, except that they are the source by which more mosquitoes become infected.

Immunochromatographic RDTs for malaria antigens, such as OptiMAL (which detects the *Plasmodium* LDH of *P. falciparum* and *vivax*) and Parasight-F (which detects the *P. falciparum* histidine-rich protein (HRP) 2), are extremely sensitive and specific for *falciparum* malaria but less so for other species. They are especially useful where the microscopist is less experienced in examining blood films (e.g. in non-endemic or remote

areas). They are less sensitive for low-level parasitaemia and positivity may persist for a month or more in some individuals. Dual *pfrp2/3* gene deletion leads to false-negative HRP2-based tests and is increasingly reported in East Africa. The QBC Malaria Test is a fluorescence microscopy-based malaria diagnostic test that is also used.

Nucleic acid detection (PCR) is used mainly in research and is useful for determining whether a patient has a recrudescence of the same malaria parasite or a reinfection with a new parasite.

#### Management

##### Mild *P. falciparum* malaria

Since *P. falciparum* is widely resistant to chloroquine and sulfadoxine-pyrimethamine (Fansidar) almost worldwide, an artemisinin-based treatment is recommended (Box 13.57). WHO policy recommends always using ACT, e.g. co-artemether or artesunate-amodiaquine. Unfortunately, artemisinin resistance has now been reported in South-east Asia, mandating strict adherence to local guidance on the selection of ACT, e.g. dihydroartemisinin-piperaquine or pyronaridine-artesunate in Thailand.

##### Complicated *P. falciparum* malaria

Severe malaria should be considered in any non-immune patient with a parasite count greater than 2% or with complications, and is a medical emergency (see Box 13.56). Management includes early and appropriate antimalarial chemotherapy, active treatment of complications, correction of fluid, electrolyte and acid-base balance, and avoidance of harmful ancillary treatments.

## 13.57 Malaria treatment

**Mild *falciparum* malaria****Preferred therapy**

- Co-artemether (CoArtem or Riamet); contains artemether and lumefantrine (4 tablets orally at 0, 8, 24, 36, 48 and 60 hrs)

**Alternative therapy**

- Quinine (600 mg of quinine salt 3 times daily orally for 5–7 days), together with or followed by doxycycline (200 mg once daily orally for 7 days)
  - Use clindamycin not doxycycline if the patient is a pregnant woman or young child
- or
- Atovaquone–proguanil (Malarone, 4 tablets orally once daily for 3 days)

**Pregnancy**

- Co-artemether but avoid in early pregnancy
- If not using co-artemether, use quinine plus clindamycin (450 mg 3 times daily orally for 7 days)

**Other regimens**

- Artesunate (200 mg orally daily for 3 days) and mefloquine (1 g orally on day 2 and 500 mg orally on day 3)

**Severe *falciparum* malaria****Preferred therapy**

- Artesunate 2.4 mg/kg IV at 0, 12 and 24 hrs and then once daily for 7 days. Once the patient is able to recommence oral intake, switch to 2 mg/kg orally once daily, to complete a total cumulative dose of 17–18 mg/kg

**Alternative therapy**

- Quinine, loading dose 20 mg/kg IV over 4 hrs, up to a maximum of 1.4 g, then maintenance doses of 10 mg/kg quinine salt given as 4-hr infusions 3 times daily for the first 48 hrs then twice a day, up to a maximum of 700 mg per dose or until the patient can take drugs orally. Combine with doxycycline (or clindamycin if there are contraindications to doxycycline)
- Note the loading dose should not be given if quinine, quinidine or mefloquine has been administered in the previous 24 hrs
- Patients should be monitored by ECG while receiving quinine, with special attention to QRS duration and QT interval

**Non-*falciparum* malaria****Preferred therapy**

- Chloroquine: 600 mg chloroquine base orally, followed by 300 mg base in 6 hrs, then 150 mg base twice daily for 2 more days plus primaquine (30 mg orally daily (for *P. vivax*) or 15 mg orally daily (for *P. ovale*) for 14 days) after confirming G6PD-negative

**Patients with mild to moderate G6PD deficiency and *P. vivax* or *P. ovale***

- Chloroquine plus primaquine 0.75 mg/kg weekly orally for 8 weeks

**Chloroquine-resistant *P. vivax***

- Co-artemether as for *P. falciparum*

(ECG = electrocardiogram; G6PD = glucose-6-phosphate dehydrogenase; IV = intravenous)

The treatment of choice is intravenous artesunate. Late haemolysis is a treatment side-effect in some patients. Rectal administration of artesunate is also being developed to allow administration in remote rural areas. Quinine salt is the alternative.

Exchange transfusion has not been tested in randomised controlled trials but may be beneficial for non-immune patients with persisting high parasitaemias (>10% circulating erythrocytes).

**Non-*falciparum* malaria**

*P. vivax*, *P. ovale*, *P. knowlesi* and *P. malariae* infections should be treated with oral chloroquine but some chloroquine resistance has been reported from Indonesia and all are sensitive to ACTs. ‘Radical cure’ is essential in patients with *P. vivax* or *P. ovale* malaria using a course of primaquine or tafenoquine, which destroys the hypnozoite phase in the liver. Severe haemolysis may develop in those who are G6PD-deficient. Cyanosis due to the formation of methaemoglobin in the red cells is more common but not dangerous (see Fig. 10.1).

**Prevention**

Clinical attacks of malaria may be preventable with chemoprophylaxis using chloroquine, atovaquone plus proguanil (Malarone), doxycycline or

13.58 Chemoprophylaxis of malaria<sup>1</sup>

Antimalarial tablets	Adult prophylactic dose	Regimen
<b>Chloroquine resistance high</b>		
Mefloquine <sup>2</sup>	250 mg weekly	Started 2–3 weeks before travel and continued until 4 weeks after
or Doxycycline <sup>3,4</sup>	100 mg daily	Started 1 week before and continued until 4 weeks after travel
or Atovaquone plus proguanil (Malarone) <sup>4</sup>	1 tablet daily	From 1–2 days before travel until 1 week after return
<b>Chloroquine resistance absent</b>		
Chloroquine <sup>5</sup> and proguanil	300 mg base weekly 100–200 mg daily	Started 1 week before and continued until 4 weeks after travel

<sup>1</sup>Choice of regimen is determined by area to be visited, length of stay, level of malaria transmission, level of drug resistance, presence of underlying disease in the traveller and concomitant medication taken. <sup>2</sup>Contraindicated in the first trimester of pregnancy, lactation, cardiac conduction disorders, epilepsy, psychiatric disorders; may cause neuropsychiatric disorders. <sup>3</sup>Causes photosensitisation and sunburn if high-protection sunblock is not used. <sup>4</sup>Avoid in pregnancy. <sup>5</sup>British preparations of chloroquine usually contain 150 mg base, French preparations 100 mg base and American preparations 300 mg base.

mefloquine. Box 13.58 gives the recommended doses for protection of the non-immune. The risk of malaria in the area to be visited and the degree of chloroquine resistance guide the recommendations for prophylaxis. Updated recommendations are summarised at fitfortravel.nhs.uk. Mefloquine is useful in areas of multiple drug resistance, such as East and Central Africa and Papua New Guinea. Experience shows it to be safe for at least 2 years but there are several contraindications to its use (see Box 13.58).

Expert advice is required for individuals unable to tolerate the first-line agents listed or in whom they are contraindicated. Mefloquine should be started 2–3 weeks before travel to give time for assessment of side-effects. Chloroquine should not be taken continuously as a prophylactic for more than 5 years without regular ophthalmic examination, as it may cause irreversible retinopathy. Pregnant and lactating women may take proguanil or chloroquine safely.

Prevention also involves advice about the use of high-percentage diethyltoluamide (DEET), covering up extremities when out after dark, and sleeping under permethrin-impregnated mosquito nets.

**Malaria control in endemic areas**

There are major initiatives to reduce and eliminate malaria in endemic areas, particularly 11 countries with the greatest burden (e.g. the ‘High Burden High Impact’ approach). Successful programmes combine vector control, including indoor residual spraying, use of long-lasting insecticide-treated bed nets (ITNs) and intermittent preventative therapy (IPT; repeated dose of prophylactic drugs in high-risk groups, such as children and pregnant women, which reduces malaria and anaemia).

Research to produce a fully protective malaria vaccine is ongoing. An adjuvanted vaccine using the R21 vaccine candidate has shown good efficacy in African children under 18 months and has progressed to phase III studies.

**Babesiosis**

Babesiosis is a tick-borne intra-erythrocytic protozoan parasite. There are more than 100 species of *Babesia*, all of which have an animal reservoir, typically either rodents or cattle. These are transmitted to humans via the tick vector *Ixodes scapularis*. Most American cases of babesiosis are due to *B. microti* and most European cases to *B. divergens*. Patients present

with fever and malaise 1–4 weeks after a tick bite. Illness may be complicated by haemolytic anaemia. Severe illness is seen in splenectomised patients. The diagnosis is made by blood-film examination. Treatment is with azithromycin and atovaquone or quinine and clindamycin.

### African trypanosomiasis (sleeping sickness)

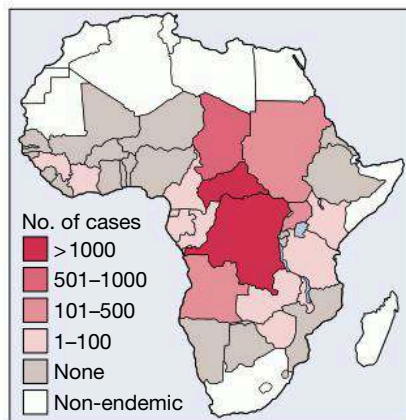

African sleeping sickness is caused by trypanosomes (Fig. 13.38) carried by tsetse flies, and is unique to sub-Saharan Africa (Fig. 13.39). The incidence of sleeping sickness across Africa has declined 95% since 1999 to <1000 cases per year. It is now on the verge of eradication. *Trypanosoma brucei gambiense* trypanosomiasis is found in West and Central Africa and causes 98% of human African trypanosomiasis (HAT). *T. brucei rhodesiense* trypanosomiasis occurs in East and Central Africa. In West Africa, transmission is mainly at the river-side, where the fly rests in the shade of trees; no animal reservoir has been identified for *T. gambiense*. *T. rhodesiense* has a large reservoir in numerous wild animals and transmission takes place in the shade of woods bordering grasslands. Rural populations employed in agriculture, fishing and animal husbandry are susceptible. Local people and tourists visiting forests infested with tsetse flies and animal reservoirs may become infected.

#### Clinical features

A bite by a tsetse fly is painful and commonly becomes inflamed; if trypanosomes are introduced, the site may again become painful and swollen about 10 days later ('trypanosomal chancre'), associated with

**Fig. 13.38** Trypanosomiasis. Scanning electron micrograph showing trypanosomes swimming among erythrocytes.

**Fig. 13.39** Distribution of human African trypanosomiasis. Data are from 2009. From Simarro PP, Diarra A, Ruiz Postigo JA, et al. The human African trypanosomiasis control and surveillance programme of the World Health Organization 2000–2009: the way forward. *PLoS Negl Trop Dis* 2011; 5(2):e1007.

regional lymphadenopathy. Within 2–3 weeks of infection, the trypanosomes invade the blood stream. The disease is characterised by an early haematolymphatic (stage 1) and a late chronic encephalopathy phase (stage 2).

#### Rhodesiense infections

This disease is more acute and severe than in *gambiense* infections. Within days or a few weeks, the patient is usually severely ill and may have developed pleural effusions and signs of myocarditis or hepatitis. There may be a petechial rash. The patient may die before there are signs of involvement of the CNS. If the illness is less acute, drowsiness, tremors and coma develop.

#### Gambiense infections

The distinction between early and late stages may not be apparent in *gambiense* infections. The disease usually runs a slow course over months or years, with irregular bouts of fever and enlargement of lymph nodes. These are characteristically firm, discrete, rubbery and painless, and are particularly prominent in the posterior triangle of the neck. Hepatosplenomegaly may develop. After some months without treatment, the CNS is invaded. Patients develop headache, altered behaviour, blunting of higher mental functions, insomnia by night and sleepiness by day, delirium and eventually tremors, pareses, wasting, coma and death.

#### Investigations

Trypanosomiasis should be considered in any febrile patient from an endemic area. In *rhodesiense* infections, thick and thin malaria blood films will reveal trypanosomes. The trypanosomes may be seen in the blood or from puncture of the primary lesion in the earliest stages of *gambiense* infections, but it is usually easier to demonstrate them by aspiration of a lymph node. Concentration methods include buffy coat microscopy and miniature anion exchange chromatography.

Due to the cyclical nature of parasitaemia, the diagnosis is often made by demonstration of antibodies using a simple, rapid screening card agglutination trypanosomiasis test (CATT) for *gambiense* HAT, followed by parasitological confirmation.

No reliable serological test is available for *rhodesiense* HAT. PCR diagnosis is available, although technical requirements limit its availability. If the CNS is affected, the cell count and protein content of the CSF are increased and the glucose is diminished. A very high level of serum IgM or the presence of IgM in the CSF is suggestive of trypanosomiasis. Recognition of CNS involvement is critical, as failure to treat it might be fatal.

#### Management

The prognosis is good if treatment is begun early, before the brain has been invaded. At this stage, intravenous suramin, after a test dose of 100–200mg, should be given for *rhodesiense* infections, followed by five injections of 20mg/kg every 7 days. Fexinidazole, an oral nitroimidazole derivative, acts on the parasite nitroreductase. It is the preferred treatment for stage 1 or stage 2 infections with a CSF white cell count <0.1 × 10<sup>9</sup>/L *gambiense* infections. The adult dose is 1800mg days 1–4, and 1200mg days 5–10, taken with food. For adults weighing <35kg the loading dose is 1200mg (days 1–4) followed by 600mg (days 5–10). For *gambiense* infections, deep intramuscular or intravenous pentamidine 4mg/kg for 7 days is now used mainly in children <6 years of age with stage 1 disease.

For the treatment of stage 2 (nervous system) infection caused by *gambiense* HAT with CSF white cell count ≥0.1 × 10<sup>9</sup>/L or in whom a CSF exam is indicated but not performed, nifurtimox (15mg/kg daily orally in three divided doses for 10 days) and eflornithine (DFMO; 400mg/kg in two 2-hour IV infusions for 7 days) combination therapy (NECT) is recommended. DFMO, an irreversible inhibitor of ornithine decarboxylase was formerly given without nifurtimox (100mg/kg IV 4 times daily for 14 days). This regimen had more side-effects and more injections. Stage 2 *rhodesiense* infection is treated with melarsoprol, an arsenical (2.2mg/kg IV for 10 days). Treatment-related mortality with melarsoprol is 4–12% due to reactive encephalopathy.

## Prevention

In endemic areas, various measures are taken against tsetse flies, and field teams help detect and treat early HAT.

## American trypanosomiasis (Chagas' disease)

Chagas' disease occurs widely in South and Central America. The cause is *Trypanosoma cruzi*, transmitted to humans from the faeces of a reduviid (triatomine) bug, in which the trypanosomes develop. These bugs live in wild forests in crevices, burrows and palm trees. The *Triatoma infestans* bug has become domesticated in the Southern Cone countries (Argentina, Brazil, Chile, Paraguay and Uruguay). It lives in the mud and wattle walls and thatched roofs of simple rural houses and emerges at night to feed and defecate on the sleeping occupants. Infected faeces are rubbed in through the conjunctiva, mucosa of mouth or nose, or abrasions of the skin. Over 100 species of mammal – domestic, peridomestic and wild – may serve as reservoirs of infection. In some areas, blood transfusion accounts for about 5% of cases. Congenital transmission occasionally occurs.

## Pathology

The trypanosomes migrate via the blood stream, develop into amastigote forms in the tissues and multiply intracellularly by binary fission. In the acute phase, inflammation (primarily cell-mediated) of parasitised, as well as non-parasitised, cardiac muscles and capillaries occurs, resulting in acute myocarditis. In the chronic phase, focal myocardial atrophy, signs of chronic passive congestion and thromboembolic phenomena, cardiomegaly and apical cardiac aneurysm are salient findings. In the digestive form of disease, focal myositis and discontinuous lesions of the intramural myenteric plexus are seen, predominantly in the oesophagus and colon.

## Clinical features

### Acute phase

Clinical manifestations of the acute phase are seen in only 1%–2% of individuals infected before the age of 15 years. Young children (1–5 years) are most commonly affected. The entrance of *T. cruzi* through an abrasion produces a dusky-red, firm swelling and enlargement of regional lymph nodes. A conjunctival lesion, although less common, is characteristic; the unilateral firm, reddish swelling of the lids may close the eye and constitutes 'Romaña's sign'. In a few patients, an acute generalised infection soon appears, with a transient morbilliform or urticarial rash, fever, lymphadenopathy and enlargement of the spleen and liver. In a small minority of patients, acute myocarditis and heart failure or neurological features, including personality changes and signs of meningoencephalitis, may be seen. The acute infection may be fatal to infants.

### Chronic phase

About 50%–70% of infected patients become seropositive and develop an indeterminate form when parasitaemia occurs only at low levels and is not usually detectable. They have a normal lifespan with no symptoms but are a natural reservoir for the disease and maintain the life cycle of parasites in tissues. After a latent period of several years, 10%–30% of chronic cases develop low-grade myocarditis and damage to conducting fibres, which causes cardiomyopathy characterised by cardiac dilatation, arrhythmias, partial or complete heart block and sudden death. In nearly 10% of patients, damage to Auerbach's plexus results in dilatation of various parts of the alimentary canal, especially the colon and oesophagus, so-called 'mega' disease. Dilatation of the bile ducts and bronchi are also recognised sequelae. Autoimmune processes may be responsible for much of the damage. There are geographical variations of the basic pattern of disease. Reactivation of Chagas' disease can occur in patients with HIV if the CD4 count falls lower than 200 cells/mm<sup>3</sup>; this can cause space-occupying lesions with a presentation similar to *Toxoplasma gondii* encephalitis in HIV, a more diffuse encephalitis, meningoencephalitis or myocarditis.

## Investigations

*T. cruzi* is easily detectable by direct microscopic examination in a blood film in the acute illness. In chronic disease, antibody detection is highly sensitive, and a positive result with two different serological tests confirms the infection parasite. DNA detection by PCR in the patient's blood is a highly sensitive method for documentation of infection.

## Management and prevention

Parasitocidal agents are used to treat the acute phase, congenital disease and early chronic phase (within 10 years of infection). Benznidazole is given at a dose of 5–8 mg/kg daily orally, in two divided doses for 60 days. Nifurtimox is an alternative treatment dosed at 8–20 mg/kg orally in three divided doses for 60 days. All doses of either treatment are weight adjusted. Treatment with either agent has to be carefully supervised to minimise toxicity while preserving parasitocidal activity. Cure rates of 80% in acute disease are obtained. Both benznidazole and nifurtimox are toxic, with adverse reaction rates of 30%–55%. Parasitocidal treatment of the chronic phase is usually performed but, in the cardiac or digestive 'mega' diseases, does not reverse tissue damage. Surgery may be needed.

Preventative measures include improvement of housing and destruction of reduviid bugs by spraying of houses with insecticides. Blood and organ donors should be screened.

## Toxoplasmosis

*Toxoplasma gondii* is an intracellular parasite. The sexual phase of the parasite's life cycle (Fig. 13.40) occurs in the small intestinal epithelium of the domestic cat. Oöcysts in cat faeces are spread to intermediate hosts (pigs, sheep and also humans) via soil contamination. Oöcysts may survive in moist conditions for weeks or months. After ingestion, the parasite transforms into rapidly dividing tachyzoites through cycles

Fig. 13.40 Life cycle of *Toxoplasma gondii*.

of asexual multiplication. Microscopic tissue cysts develop containing bradyzoites, which persist for the lifetime of the host. Cats become infected or reinfected by ingesting tissue cysts in prey such as rodents and birds.

Human infection occurs via oöcyst-contaminated soil, salads and vegetables, or by ingestion of raw or under-cooked meats containing tissue cysts. Sheep, pigs and rabbits are the most common meat sources. Outbreaks of toxoplasmosis have followed consumption of unfiltered water. In high-income countries, toxoplasmosis is the most common protozoal infection; around 22% of adults in the UK are seropositive. Most primary infections are subclinical; however, toxoplasmosis is thought to account for about 15% of heterophile antibody-negative infectious mononucleosis. In India or Brazil, approximately 40%–60% of pregnant females are seropositive for *T. gondii*. Toxoplasmosis is an important opportunistic infection in people with HIV, with considerable morbidity and mortality. Generalised toxoplasmosis has followed occupational exposure of laboratory workers.

### Clinical features

In most immunocompetent individuals, including children and pregnant women, the infection goes unnoticed. In approximately 10% of patients, it causes a self-limiting illness, most often in adults aged 25–35 years. The presenting feature is usually localised or generalised painless lymphadenopathy. The cervical nodes are primarily involved but mediastinal, mesenteric or retroperitoneal groups may be affected. The spleen is seldom palpable. Most patients have no systemic symptoms but some complain of malaise, fever, fatigue, muscle pain, sore throat and headache. Complete resolution usually occurs within a few months, although symptoms and lymphadenopathy tend to fluctuate unpredictably and some patients do not recover completely for a year or more. Encephalitis, myocarditis, polymyositis, pneumonitis or hepatitis occasionally occur in immunocompetent patients but are more frequent in immunocompromised hosts. Retinochoroiditis (Fig. 13.41) is usually the result of congenital infection but has also been reported in acquired disease.

### Congenital toxoplasmosis

Acute toxoplasmosis, mostly subclinical, affects 0.3%–1% of pregnant women, with approximately 60% transmission rate to the fetus, which rises with increasing gestation. Seropositive females infected 6 months before conception have no risk of fetal transmission. Congenital disease affects approximately 40% of infected fetuses, and is more likely and more severe with infection early in gestation (see Box 13.24). Many fetal infections are subclinical at birth but long-term sequelae include retinochoroiditis, microcephaly and hydrocephalus.

Fig. 13.41 Retinochoroiditis due to toxoplasmosis.

### Investigations

In contrast to immunocompromised patients, in whom the diagnosis often requires direct detection of parasites, serology is often used in immunocompetent individuals. The Sabin–Feldman dye test (indirect fluorescent antibody test), which detects IgG antibody, is most commonly used. Recent infection induces a fourfold or greater increase in titre when paired sera are tested. Peak titres  $\geq 1/1000$  are reached 1–2 months after infection, and serology then becomes an unreliable indicator of recent infection. The detection of significant levels of *Toxoplasma*-specific IgM antibody may be useful in confirming acute infection. A false-positive result or persistence of IgM antibodies for years after infection makes interpretation difficult; however, negative IgM antibodies virtually rule out acute infection.

During pregnancy, it is critical to differentiate recent from past infection; the presence of high-avidity IgG antibodies excludes infection acquired in the preceding 3–4 months.

If necessary, the presence of *Toxoplasma* organisms in a lymph node biopsy or other tissue can be detected histochemically with *T. gondii* antiserum, or by the use of PCR to detect *Toxoplasma*-specific DNA.

### Management

In immunocompetent subjects, uncomplicated toxoplasmosis is self-limiting and responds poorly to antimicrobial therapy. Treatment with sulfadiazine, pyrimethamine and folinic acid is usually reserved for severe or progressive disease, and for infection in immunocompromised patients. Often empirical treatment is initiated in people living with HIV if space-occupying lesions are found in the CNS (see Ch. 14).

In pregnant women with established recent infection, spiramycin (3 g daily in divided doses) is given until term. Once fetal infection is established, treatment with sulfadiazine and pyrimethamine plus calcium folinate is recommended (spiramycin does not cross the placental barrier). The cost/benefit of routine *Toxoplasma* screening and treatment in pregnancy is being debated in many countries. There is insufficient evidence to determine the effects on mother or baby of current antiparasitic treatment for women who seroconvert in pregnancy.

## Leishmaniasis

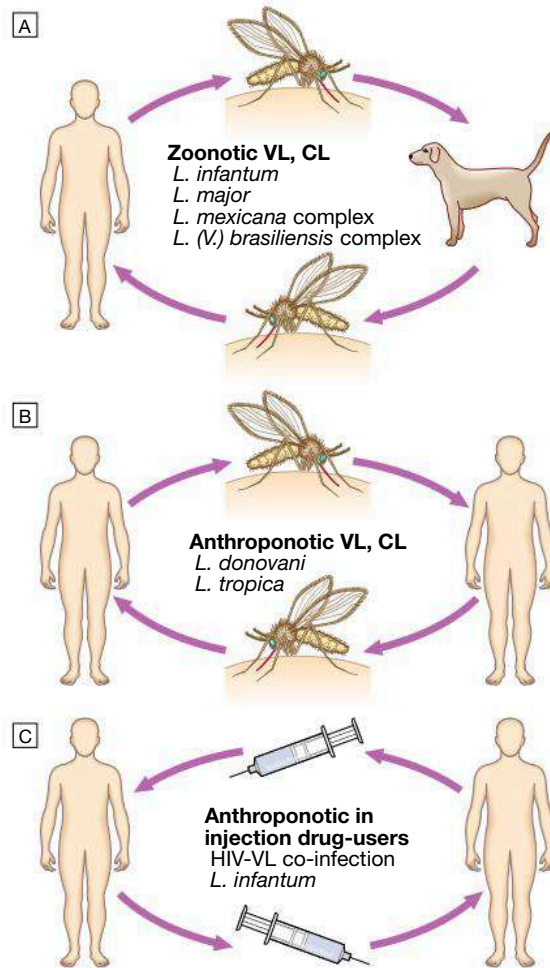

Leishmaniasis is caused by unicellular, flagellate, intracellular protozoa belonging to the genus *Leishmania* (order Kinetoplastidae). The 21 leishmanial species that cause human disease are responsible for three clinical syndromes:

- visceral leishmaniasis (VL, kala-azar)
- cutaneous leishmaniasis (CL)
- mucosal leishmaniasis (ML).

### Epidemiology and transmission

Although most clinical syndromes are caused by zoonotic transmission of parasites from animals (chiefly canine and rodent reservoirs) to humans through phlebotomine sandfly vectors (Fig. 13.42A), humans are the only known reservoir (anthroponotic person-to-person transmission) in major VL foci in South Asia and in injection drug-users (Fig. 13.42B and C). Leishmaniasis occurs in approximately 100 countries around the world, with an estimated annual incidence of 1 million new cases, of which VL contributes approximately 20 000 cases.

The life cycle of *Leishmania* is shown in Figure 13.43. Flagellar promastigotes (10–20  $\mu\text{m}$ ) are introduced by the feeding female sandfly. The promastigotes are taken up by neutrophils, which undergo apoptosis and are then engulfed by macrophages, in which the parasites transform into amastigotes (2–4  $\mu\text{m}$ ; Leishman–Donovan body). These multiply, causing macrophage lysis and infection of other cells. Sandflies pick up amastigotes when feeding on infected patients or animal reservoirs. In the sandfly, the parasite transforms into a flagellar promastigote, which multiplies by binary fission in the gut of the vector and migrates to the proboscis to infect a new host.

**Fig. 13.42** Transmission of leishmaniasis. **A** Zoonotic transmission. **B** Anthroponotic transmission. **C** Anthroponotic transmission in the injection drug-user. (CL = cutaneous leishmaniasis; HIV = human immunodeficiency virus; VL = visceral leishmaniasis)

Sandflies live in hot and humid climates in the cracks and crevices of mud or straw houses and lay eggs in organic matter. People living in such conditions are more prone to leishmaniasis. Female sandflies bite during the night and preferentially feed on animals; humans are incidental hosts.

### Visceral leishmaniasis (kala-azar)

VL is caused by the protozoan *Leishmania donovani* complex (comprising *L. donovani*, *L. infantum* and *L. chagasi*). India, Sudan, South Sudan, Ethiopia and Brazil account for 90% of cases of VL. Other affected regions include the Mediterranean, East Africa, China, Arabia, Israel and other South American countries (Fig. 13.44). In addition to sandfly transmission, VL can result from blood transfusion, and disease can present unexpectedly in immunosuppressed patients – for example, after renal transplantation and in HIV infection.

The majority of infections remain asymptomatic. In visceral disease, the spleen, liver, bone marrow and lymph nodes are primarily involved.

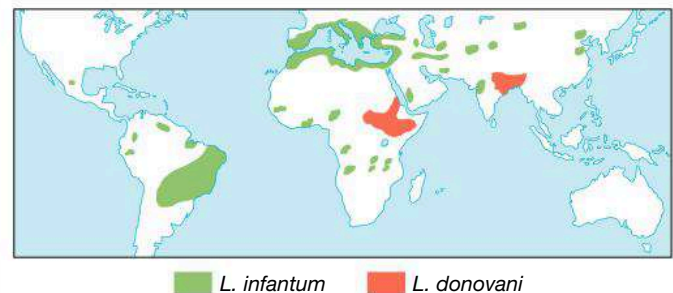

#### Clinical features

In South Asia, adults and children are equally affected; elsewhere, VL is mainly a disease of small children and infants, except in adults with HIV co-infection. The incubation period ranges from weeks to months (occasionally, several years).

The first sign of infection is high fever, usually accompanied by rigor and chills. Fever intensity decreases over time and patients may become afebrile for weeks to months. This is followed by a relapse of fever,

**Fig. 13.43** Life cycle of *Leishmania*. From Knight R. *Parasitic disease in man*. Edinburgh: Churchill Livingstone, Elsevier Ltd; 1982.

**Fig. 13.44** World distribution of visceral leishmaniasis.

often of lesser intensity. Splenomegaly develops quickly in the first few weeks and becomes massive as the disease progresses. Moderate hepatomegaly occurs later. Lymphadenopathy is common in Africa, the Mediterranean and South America but is rare in South Asia. Blackish discoloration of the skin, from which the disease derived its name, kala-azar (the Hindi word for 'black fever'), is a feature of advanced illness but is now rarely seen. Pancytopenia is common. Moderate to severe anaemia develops rapidly and can cause cardiac failure. Thrombocytopenia, often compounded by hepatic dysfunction, may result in bleeding from the retina, gastrointestinal tract and nose. In advanced illness, hypoalbuminaemia may manifest as pedal oedema, ascites and anasarca (gross generalised oedema and swelling).

As disease progresses, there is profound immunosuppression and secondary infections are very common. These include tuberculosis, pneumonia, gastroenteritis, severe amoebic or bacillary dysentery, boils, cellulitis, chickenpox, shingles and scabies. Without adequate treatment, most patients with clinical VL die.

#### Investigations

Pancytopenia is the dominant feature, with granulocytopenia. Polyclonal hypergammaglobulinaemia, chiefly IgG followed by IgM, and hypoalbuminaemia are seen later.

**Fig. 13.45** Splenic smear showing numerous intracellular, and a few extracellular, amastigotes. Courtesy of Dr S. Sundar and Dr H.W. Murray.

Demonstration of amastigotes (Leishman–Donovan bodies) in splenic smears is the most efficient means of diagnosis, with 98% sensitivity (Fig. 13.45); however, it carries a risk of serious haemorrhage in inexperienced hands. Safer methods, such as bone marrow or lymph node smears, are less sensitive but are frequently employed. Parasites may be demonstrated in buffy coat smears, especially in immunosuppressed patients. Sensitivity is improved in specialised laboratories by culturing the aspirate material or by using PCR for DNA detection and species identification.

Serodiagnosis, by ELISA or immunofluorescence antibody test, is employed where resources allow. In endemic regions, a highly sensitive direct agglutination test using stained promastigotes and an equally efficient rapid immunochromatographic k39 strip test have become popular. These tests remain positive for several months to years after cure has been achieved, so do not predict response to treatment or relapse. The vast majority of people exposed to the parasite do not develop clinical illness but may have positive serological tests thereafter. Formal gel (aldehyde) or other similar tests based on the detection of raised globulin have no value and are not recommended for the diagnosis of VL.

### Differential diagnosis

This includes malaria, typhoid, tuberculosis, schistosomiasis and many other infectious and neoplastic conditions, some of which may coexist with VL. Fever, splenomegaly, pancytopenia and non-response to anti-malarial therapy may provide clues before specific laboratory diagnosis is made.

### Management

#### Pentavalent antimonials

Antimony (Sb) compounds were the first drugs to be used for the treatment of leishmaniasis and remain the mainstay of treatment in most parts of the world. The exception is South Asia, especially the Indian state of Bihar, where almost two-thirds of cases are refractory to Sb treatment. Traditionally, pentavalent antimony is available as sodium stibogluconate (100 mg/mL) in English-speaking countries and meglumine antimoniate (85 mg/mL) in French-speaking ones. The daily dose is 20 mg/kg body weight, intravenously or intramuscularly, for 28–30 days. Side-effects are common and include arthralgia, myalgia, raised hepatic transaminases, pancreatitis (especially in patients co-infected with HIV) and ECG changes (T-wave inversion and reduced amplitude). Severe cardiotoxicity, manifest by concave ST segment elevation, prolongation of QT<sub>c</sub> greater than 0.5 msec and ventricular dysrhythmias, is not uncommon. The incidence of cardiotoxicity and death is particularly high with improperly manufactured Sb.

#### Amphotericin B

Amphotericin B deoxycholate, given once daily or on alternate days at a dose of 0.75–1.00 mg/kg for 15–20 doses, is used as the first-line drug in many regions where there is a significant level of Sb unresponsiveness. It has a cure rate of nearly 100%. Infusion-related side-effects, such as high fever with rigor, thrombophlebitis, diarrhoea and vomiting, are extremely common. Serious side-effects, including renal or hepatic toxicity, hypokalaemia and thrombocytopenia, are observed frequently.

Lipid formulations of amphotericin B are less toxic. Liposomal amphotericin B (Ambisome) is first-line therapy in Europe for VL. Dosing recommendations vary according to geographical region. In South Asia, a total dose of 10 or 15 mg/kg, administered in a single dose or as multiple doses over several days, respectively, is considered adequate, whereas in Africa 14–18 mg/kg, and in South America and Europe 21–24 mg/kg, in 5–7 divided doses, is recommended for immunocompetent patients. High daily doses of the lipid formulations are well tolerated, and in one study a single dose of 10 mg/kg of AmBisome cured 96% of Indian patients. This regimen is used as first-line therapy in the Kala-azar Elimination Programme in India, Nepal and Bangladesh.

#### Other drugs

The oral drug miltefosine, an alkyl phospholipid, has been approved in several countries for the treatment of VL. A daily dose of 50 mg (patient's body weight <25 kg) to 100 mg (≥25 kg), or 2.5 mg/kg for children, for 28 days, cures over 90% of patients. Side-effects include mild to moderate vomiting and diarrhoea, and rarely skin allergy or renal or liver toxicity. Since it is a teratogenic drug, it cannot be used in pregnancy; female patients are advised not to become pregnant for the duration of treatment and 3 months thereafter because of its half-life of nearly 1 week.

Paromomycin is an aminoglycoside that has undergone trials in India and Africa, and is highly effective if given intramuscularly at 11 mg/kg of paromomycin base, daily for 3 weeks. No significant auditory or renal toxicity is seen. The drug is approved in India for VL treatment.

Pentamidine isethionate was used to treat Sb-refractory patients with VL. However, declining efficacy and serious side-effects, such as type 1 diabetes mellitus, hypoglycaemia and hypotension, have led to it being abandoned.

Multidrug therapy of VL is likely to be used increasingly to prevent emergence of drug resistance, and in India short-course combinations (a single dose of AmBisome 5 mg/kg with either 7 days of miltefosine or 10 days of paromomycin, or 10 days each of miltefosine and paromomycin) were as effective as standard therapy. In India, in treatment centres where the cold chain (a temperature-controlled supply chain) is not maintained, 10 days of paromomycin combined with miltefosine is an alternative treatment regimen.

#### Response to treatment

A good response results in fever resolution, improved well-being, reduction in splenomegaly, weight gain and recovery of blood counts. Patients require 6–12 months of regular follow-up, as some may experience relapse irrespective of the treatment regimen.

#### HIV–visceral leishmaniasis co-infection

HIV-induced immunosuppression (Ch. 14) increases the risk of contracting VL 100–1000 times. Most cases of HIV–VL co-infection have been reported from Spain, France, Italy and Portugal, but antiretroviral therapy (ART) has led to a remarkable decline. HIV-associated VL is also reported in Africa (mainly Ethiopia), Brazil and South Asia.

Although the clinical triad of fever, splenomegaly and hepatomegaly is found in the majority of co-infected patients, those with low CD4 count may have atypical clinical presentations. VL may present with gastrointestinal involvement (stomach, duodenum or colon), ascites, pleural or pericardial effusion, or involvement of lungs, tonsil, oral mucosa or skin. Diagnostic principles remain the same as those in non-HIV patients. Parasites are numerous and easily demonstrable, even in buffy coat

preparations. Sometimes amastigotes are found in unusual sites, such as bronchoalveolar lavage fluid, pleural fluid or biopsies of the gastrointestinal tract. Serological tests have low sensitivity. DNA detection by PCR of the blood or its buffy coat is at least 95% sensitive and accurately tracks recovery and relapse.

Treatment of VL with HIV co-infection is essentially the same as in immunocompetent patients but there are some differences in outcome. Conventional amphotericin B (0.7 mg/kg daily for 28 days) may be more effective in achieving initial cure than Sb (20 mg/kg daily for 28 days). Using high-dose liposomal amphotericin B (4 mg/kg on days 1–5, 10, 17, 24, 31 and 38), a high cure rate is possible. However, co-infected patients have a tendency to relapse within 1 year and maintenance chemotherapy with monthly liposomal amphotericin B is useful.

### Post-kala-azar dermal leishmaniasis

After treatment and apparent recovery from VL in India and Sudan, some patients develop dermatological manifestations due to local parasitic infection.

#### Clinical features

In India, dermatological changes occur in a small minority of patients 6 months to at least 3 years after the initial infection. They are seen as macules, papules, nodules (most frequently) and plaques, which have a predilection for the face, especially the area around the chin. The face often appears erythematous (Fig. 13.46A). Hypopigmented macules can occur over all parts of the body and are highly variable in extent. There are no systemic symptoms and little spontaneous healing occurs.

In Sudan and South Sudan, approximately 50% of patients with VL develop post-kala-azar dermal leishmaniasis (PKDL), experiencing skin manifestations concurrently with VL or within 6 months. In addition to the dermatological features, a measles-like maculopapular rash (Fig. 13.46B) may be seen all over the body. In Sudan, children are more frequently affected than in India. Spontaneous healing occurs in about three-quarters of cases within 1 year.

#### Investigations and management

The diagnosis is clinical, supported by demonstration of scanty parasites in lesions by slit-skin smear and culture. Immunofluorescence and immunohistochemistry may demonstrate the parasite in skin tissues. In the majority of patients, serological tests (direct agglutination test or k39 strip tests) are positive.

Treatment of PKDL is difficult. In India, Sb for 120 days, several courses of amphotericin B infusions, or miltefosine for 12 weeks is required. In Sudan, Sb for 2 months is considered adequate. In the absence of a physical handicap, most patients are reluctant to complete therapy. PKDL patients are a human reservoir, and focal outbreaks have been linked to patients with PKDL in areas previously free of VL. PKDL and cases with active VL infected sandflies efficiently in xenodiagnosis experiments done in India and Bangladesh.

### Prevention and control

Sandfly control through insecticide spray is very important. Mosquito nets or curtains treated with insecticides will keep out the tiny sandflies. In endemic areas with zoonotic transmission, infected or stray dogs should be destroyed.

In areas with anthroponotic transmission, early diagnosis and treatment of human infections, to reduce the reservoir and control epidemics of VL, is extremely important. Serology is useful in diagnosis of suspected cases in the field. No vaccine is currently available.

## Cutaneous and mucosal leishmaniasis

### Cutaneous leishmaniasis

CL (oriental sore) occurs in both the Old World (Asia, Africa and Europe) and the New World (the Americas). Transmission is described in Fig. 13.42).

In the Old World, CL is mild. It is found around the Mediterranean basin, throughout the Middle East and Central Asia as far as Pakistan, and in sub-Saharan West Africa and Sudan (Fig. 13.47). The causative organisms for Old World zoonotic CL are *L. major*, *L. tropica* and *L. aethiopic* (Box 13.59). Anthroponotic CL is caused by *L. tropica*, and is confined to urban or suburban areas of the Old World. Afghanistan is currently the biggest focus but infection is endemic in Pakistan, the western deserts of India, Iran, Iraq, Syria and other areas of the Middle East. In recent years there has been an increase in the incidence of zoonotic CL in both the Old and the New Worlds due to urbanisation and deforestation, which led to peridomestic transmission (in and around human dwellings).

New World CL is a more significant disease, which may disfigure the nose, ears and mouth, and is caused by the *L. mexicana* complex (comprising *L. mexicana*, *L. amazonensis* and *L. venezuelensis*) and by the *Viannia* subgenus *L. (V.) brasiliensis* complex (comprising *L. (V.) guyanensis*, *L. (V.) panamensis*, *L. (V.) brasiliensis* and *L. (V.) peruviana*).

**Fig. 13.46** Post-kala-azar dermal leishmaniasis. **A** In India, with macules, papules, nodules and plaques. **B** In Sudan, with micronodular rash. (A) From Sundar S, Kumar K, Chakravarty J, et al. Cure of antimony-unresponsive Indian post-kala-azar dermal leishmaniasis with oral miltefosine. *Trans R Soc Trop Med Hyg* 2006; 100(7): 698–700. (B) Courtesy of Dr E.E. Zijlstra.

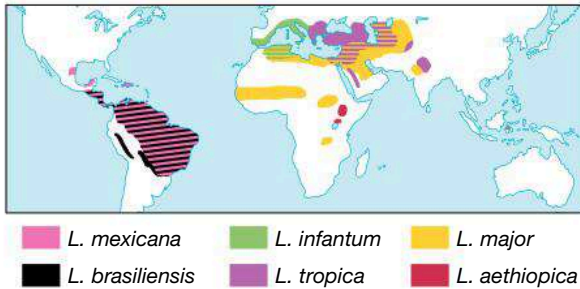

Fig. 13.47 World distribution of cutaneous leishmaniasis.

13.59 Types of Old World cutaneous leishmaniasis		
<i>Leishmania</i> spp.	Host	Clinical features
<i>L. tropica</i>	Dogs	Slow evolution, less severe
<i>L. major</i>	Gerbils, desert rodents	Rapid necrosis, wet sores
<i>L. aethiopica</i>	Hyraxes	Solitary facial lesions with satellites

CL is commonly imported and should be considered in the differential diagnosis of an ulcerating skin lesion, especially in travellers who have visited endemic areas of the Old World or forests in Central and South America.

#### Pathogenesis

Inoculated parasites are taken up by dermal macrophages, in which they multiply and form a focus for lymphocytes, epithelioid cells and plasma cells. Self-healing may occur with necrosis of infected macrophages, or the lesion may become chronic with ulceration of the overlying epidermis, depending on the aetiological pathogen.

#### Clinical features

The incubation period is typically 2–3 months (range 2 weeks to 5 years). In all types of CL a papule develops at the site of the vector bite. The small, red papules may be single or multiple and increase gradually in size, reaching 2–10 cm in diameter. A crust forms, overlying an ulcer with a granular base and with raised borders (Fig. 13.48). These ulcers develop a few weeks or months after the bite. There can be satellite lesions, especially in *L. major* and occasionally in *L. tropica* infections. Regional lymphadenopathy, pain, pruritus and secondary bacterial infections may occur.

Lesions of *L. mexicana* and *L. peruviana* closely resemble those seen in the Old World, but lesions on the pinna of the ear are common and are chronic and destructive. *L. mexicana* is responsible for chiclero ulcers, the self-healing sores of Mexico.

If immunity is effective, there is usually spontaneous healing in *L. tropica*, *L. major* and *L. mexicana* lesions. In some patients with anergy to *Leishmania*, the skin lesions of *L. aethiopica*, *L. mexicana* and *L. amazonensis* infections progress to the development of diffuse CL; this is characterised by spread of the infection from the initial ulcer, usually on the face, to involve the whole body in the form of non-ulcerative nodules. Occasionally, in *L. tropica* infections, sores that have apparently healed relapse persistently (recidivans or lupoid leishmaniasis).

#### Mucosal leishmaniasis

The *Viannia* subgenus extends widely from the Amazon basin as far as Paraguay and Costa Rica, and is responsible for deep sores and ML. In *L. (V.) brasiliensis* complex infections, cutaneous lesions may be followed by mucosal spread of the disease simultaneously or even years later. Young men with chronic lesions are particularly at risk, and 2%–40% of infected persons develop 'espundia', metastatic lesions in the mucosa of the nose or mouth. This is characterised by thickening and erythema of the nasal mucosa, typically starting at the junction of the nose and

upper lip. Later, ulceration develops. The lips, soft palate, fauces and larynx may also be invaded and destroyed, leading to considerable suffering and deformity. There is no spontaneous healing, and death may result from severe respiratory tract infections due to massive destruction of the pharynx.

#### Investigations in CL and ML

CL is often diagnosed by the clinical features. Parasitological confirmation is important, however, because clinical manifestations may be mimicked by other infections. Amastigotes can be demonstrated on a slit-skin smear with Giemsa staining; alternatively, they can be cultured from the sores early during the infection. Parasites are difficult to isolate from sores caused by *L. brasiliensis*, responsible for the vast majority of cases in Brazil. Touch preparations from biopsies and histopathology usually have a low sensitivity. Culture of fine needle aspiration material has been reported to be the most sensitive method.

ML is more difficult to diagnose parasitologically. The leishmanin skin test measures delayed-type hypersensitivity to killed *Leishmania* organisms. A positive test is defined as induration of more than 5 mm, 48 hours after intradermal injection. The test is positive, except in diffuse CL and during active VL. PCR is used increasingly for diagnosis and speciation, which is useful in selecting therapy.

#### Management of CL and ML

Small lesions may self-heal or are treated by freezing with liquid nitrogen or curettage. There is no ideal antimicrobial therapy. Treatment should be individualised on the basis of the causative organism, severity of the lesions, availability of drugs, anticipated toxicity, and local resistance patterns.

In CL, topical application of paromomycin 15% plus methylbenzethonium chloride 12% is beneficial. Intralesional antimony (Sb 0.2–0.8 mL/lesion) up to 2 g seems to be rapidly effective in suitable cases; it is well tolerated and economic, and is safe in patients with cardiac, liver or renal diseases.

In ML, and in CL when the lesions are multiple or in a disfiguring site, it is better to treat with parenteral Sb (20 mg/kg daily, usually given for 20 days for CL and 28 days for ML), or with conventional or liposomal amphotericin B (see treatment of VL above). Sb is also indicated to prevent the development of mucosal disease, if there is any chance that a lesion acquired in South America is due to an *L. brasiliensis* strain. Refractory CL or ML should be treated with an amphotericin B preparation.

Other regimens may be effective. Two to four doses of pentamidine (2–4 mg/kg), administered on alternate days, are effective in New World CL caused by *L. guyanensis*. In ML, 8 injections of pentamidine (4 mg/kg on alternate days) cure the majority of patients. Various azole compounds, fluconazole, ketoconazole and itraconazole, have similar and modest efficacy rates in the treatment of cutaneous leishmaniasis.

#### Prevention of CL and ML

Personal protection against sandfly bites is important. No effective vaccine is yet available.

## Gastrointestinal protozoal infections

### Amoebiasis

Amoebiasis is caused by *Entamoeba histolytica*, which is spread between humans by its cysts. It is one of the leading parasitic causes of morbidity and mortality in the tropics and is occasionally acquired in non-tropical countries. Two non-pathogenic *Entamoeba* species (*E. dispar* and *E. moshkovskii*) are morphologically identical to *E. histolytica*, and are distinguishable only by molecular techniques, isoenzyme studies or monoclonal antibody typing. However, only *E. histolytica* causes amoebic dysentery or liver abscess. The life cycle of the amoeba is shown in Figure 13.49A.

**Fig. 13.48** Cutaneous leishmaniasis. **A** Papule. **B** Ulcer. (B) Courtesy of Dr Ravi Gowda, Royal Hallamshire Hospital, Sheffield.

**Fig. 13.49** Amoebiasis. **A** The life cycle of *Entamoeba histolytica*. **B** The chocolate-brown appearance of aspirated material from an amoebic liver abscess. (A) From Knight R. *Parasitic disease in man*. Edinburgh: Churchill Livingstone, Elsevier Ltd; 1982. (B) Courtesy of Dr Ravi Gowda, Royal Hallamshire Hospital, Sheffield.

### Pathology

Cysts of *E. histolytica* are ingested in water or uncooked foods contaminated by human faeces. Infection may also be acquired through anal/oral sexual practices. Trophozoites emerge from the cysts in the small bowel and enter the large bowel. The parasite invades the mucous membrane of the large bowel, producing lesions that are maximal in the caecum but extend to the anal canal. These are flask-shaped ulcers, varying greatly in size and surrounded by healthy mucosa. A rare complication is amoeboma, a localised granuloma that may present as a palpable abdominal mass (usually in the right iliac fossa), a rectal mass (rarely) or a filling defect on colonic radiography. This has to be distinguished from other causes of colonic mass (e.g. cancer). Amoebic ulcers may cause severe haemorrhage but rarely perforate the bowel wall.

Amoebic trophozoites can emerge from the vegetative cyst from the bowel and be carried to the liver in a portal venule. They can multiply rapidly and destroy the liver parenchyma, causing an abscess (see also p. 891). The liquid contents at first have a characteristic pinkish colour, which may later change to chocolate-brown (said to resemble anchovy sauce).

Cutaneous amoebiasis, though rare, causes progressive genital, perianal or peri-abdominal surgical wound ulceration.

### Clinical features

#### Intestinal amoebiasis – amoebic dysentery

Most amoebic infections are asymptomatic. The incubation period of amoebiasis ranges from 2 weeks to many years, followed by a chronic course with abdominal pains and two or more unformed stools a day. Offensive diarrhoea, alternating with constipation, and blood or mucus in the stool are common. There may be abdominal pain, especially in the right lower quadrant (which may mimic acute appendicitis). A dysenteric presentation with passage of blood, simulating bacillary dysentery or ulcerative colitis, occurs particularly in older people, in the puerperium and with super-added pyogenic infection of the ulcers.

#### Amoebic liver abscess

The abscess is usually found in the right hepatic lobe. There may not be associated diarrhoea. Early symptoms may be only local discomfort and malaise; later, a swinging temperature and sweating may develop, usually without marked systemic symptoms or signs. An enlarged, tender liver, cough and pain in the right shoulder are characteristic but symptoms may remain vague and signs minimal. A large abscess may

penetrate the diaphragm, rupturing into the lung, and may be coughed up through a hepatobronchial fistula. Rupture into the pleural or peritoneal cavity, or rupture of a left lobe abscess in the pericardial sac, is less common but more serious.

### Investigations

Microscopic examination of the stool and exudate can reveal motile trophozoites containing red blood cells. Trophozoite motility decreases rapidly as the stool preparation cools. Several stools may need to be examined in chronic amoebiasis before cysts are found. Sigmoidoscopy may reveal typical flask-shaped ulcers, which should be scraped and examined immediately for *E. histolytica*. In endemic areas, one-third of the population are symptomless passers of amoebic cysts.

An amoebic abscess of the liver is suspected on clinical grounds; there is often a neutrophil leucocytosis and a raised right hemidiaphragm on chest X-ray. Confirmation is by ultrasonic scanning. Aspirated pus from an amoebic abscess has the characteristic chocolate-brown appearance but rarely contains free amoebae (Fig. 13.49B).

Serum antibodies are detectable by immunofluorescence in over 95% of patients with hepatic amoebiasis and intestinal amoeboma, but in only about 60% of dysenteric amoebiasis. DNA detection by PCR or by loop-mediated isothermal amplification (LAMP) assay have been shown to be useful in diagnosis of *E. histolytica* infections but are not generally available.

### Management

Intestinal and early hepatic amoebiasis responds quickly to oral metronidazole (800 mg 3 times daily for 5–10 days) or other long-acting nitroimidazoles like tinidazole or ornidazole (both in doses of 2 g daily for 3 days). Nitazoxanide (500 mg twice daily for 3 days) is an alternative drug. Either diloxanide furoate or paromomycin, in doses of 500 mg orally 3 times daily for 10 days after treatment, should be given to eliminate luminal cysts.

If a liver abscess is large or threatens to burst, or if the response to chemotherapy is not prompt, aspiration is required and is repeated if necessary. Rupture of an abscess into the pleural cavity, pericardial sac or peritoneal cavity necessitates immediate aspiration or surgical drainage. Small serous effusions resolve without drainage.

### Prevention

Personal precautions against contracting amoebiasis include not eating fresh, uncooked vegetables or drinking unclean water.

## Giardiasis

Infection with *Giardia lamblia* (also known as *G. intestinalis*) is found worldwide and is common in the tropics. It particularly affects children, tourists and immunosuppressed individuals, and is the parasite most commonly imported into the UK. Cysts remain viable in water for up to 3 months and infection usually occurs by ingesting contaminated water. Its flagellar trophozoite form attaches to the duodenal and jejunal mucosa, causing inflammation.

### Clinical features and investigations

After an incubation period of 1–3 weeks, there is diarrhoea, abdominal pain, weakness, anorexia, nausea and vomiting. On examination, there may be abdominal distension and tenderness. Chronic diarrhoea and malabsorption may occur, with bulky stools that float.

Stools obtained at 2–3-day intervals should be examined for cysts. Duodenal or jejunal aspiration by endoscopy gives a higher diagnostic yield. A number of stool antigen detection tests are available. Jejunal biopsy specimens may show *Giardia* on the epithelial surface. PCR/multiplex PCR are increasingly being used in the diagnosis of giardiasis, but may not be freely accessible in low-income countries.

### Management

Treatment is with a single dose of tinidazole 2 g, metronidazole 400 mg 3 times daily for 10 days, or nitazoxanide 500 mg orally twice daily for 3 days.

## Cryptosporidiosis

*Cryptosporidium* spp. are coccidian protozoal parasites of humans and domestic animals. Infection is acquired by the faecal–oral route through contaminated water supplies. The incubation period is approximately 7–10 days and is followed by watery diarrhoea and abdominal cramps. The illness is usually self-limiting but in immunocompromised patients, especially those with HIV, the illness can be devastating, with persistent severe diarrhoea and substantial weight loss. Diagnosis is by detection of oocysts on faecal microscopy or PCR of stool. Treatment is not usually required; nitazoxanide can be used in immunocompromised hosts but efficacy is uncertain.

## Cyclosporiasis

*Cyclospora cayatanensis* is a globally distributed coccidian protozoal parasite of humans. Infection is acquired by ingestion of contaminated water and recent food-borne outbreaks have been associated with raspberries and coriander (cilantro). The incubation period of approximately 2–11 days is followed by diarrhoea with abdominal cramps, which may remit and relapse. Although usually self-limiting, the illness may last as long as 6 weeks, with significant weight loss and malabsorption, and is more severe in immunocompromised individuals. Diagnosis is as for cryptosporidiosis. Treatment may be necessary in a few cases, using co-trimoxazole 960 mg twice daily for 7 days.

## Infections caused by helminths

Helminths (from the Greek *helmins*, meaning worm) include three groups of parasitic worm (Box 13.60), large multicellular organisms with complex tissues and organs.

### Intestinal human nematodes

Adult nematodes living in the human gut can cause disease. There are two types:

- the hookworms, which have a soil stage in which they develop into larvae that then penetrate the host
- a group of nematodes that survive in the soil merely as eggs, which have to be ingested for their life cycle to continue.

The geographical distribution of hookworms is limited by the larval requirement for warmth and humidity. Soil-transmitted nematode

### 13.60 Classes of helminth that parasitise humans

#### Nematodes or roundworms

- Intestinal human nematodes: *Ancylostoma duodenale*, *Necator americanus*, *Strongyloides stercoralis*, *Ascaris lumbricoides*, *Enterobius vermicularis*, *Trichuris trichiura*
- Tissue-dwelling human nematodes: *Wuchereria bancrofti*, *Brugia malayi*, *Loa loa*, *Onchocerca volvulus*, *Dracunculus medinensis*, *Mansonella perstans*, *Dirofilaria immitis*
- Zoonotic nematodes: *Trichinella spiralis*

#### Trematodes or flukes

- Blood flukes: *Schistosoma haematobium*, *S. mansoni*, *S. japonicum*, *S. mekongi*, *S. intercalatum*
- Lung flukes: *Paragonimus* spp.
- Hepatobiliary flukes: *Clonorchis sinensis*, *Fasciola hepatica*, *Opisthorchis felineus*
- Intestinal flukes: *Fasciolopsis buski*

#### Cestodes or tapeworms

- Intestinal tapeworms: *Taenia saginata*, *T. solium*, *Diphyllobothrium latum*, *Hymenolepis nana*
- Tissue-dwelling cysts or worms: *Taenia solium*, *Echinococcus granulosus*

infections can be prevented by avoidance of faecal soil contamination (adequate sewerage disposal) or skin contact (wearing shoes), and by strict personal hygiene.

### Ancylostomiasis (hookworm)

Ancylostomiasis is caused by *Ancylostoma duodenale* or *Necator americanus*. The complex life cycle is shown in Figure 13.50. The adult hookworm is 1 cm long and lives in the duodenum and upper jejunum. Eggs are passed in the faeces. In warm, moist, shady soil, the larvae develop into rhabditiform and then the infective filariform stages; they then penetrate human skin and are carried to the lungs. After entering the alveoli, they ascend the bronchi, are swallowed and mature in the small intestine, reaching maturity 4–7 weeks after infection. The worms attach to the mucosa of the small intestine by their buccal capsule (Fig. 13.51) and withdraw blood. The mean daily blood loss from one *A. duodenale* is 0.15 mL and that from *N. americanus* 0.03 mL.

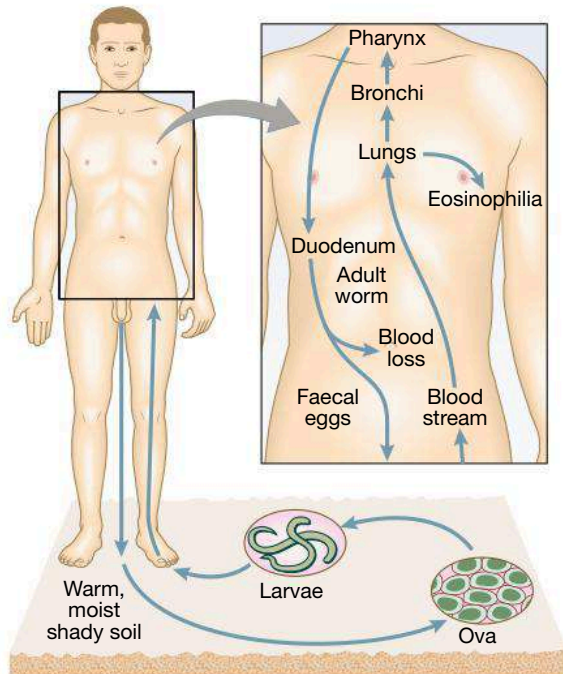

Fig. 13.50 Ancylostomiasis. Life cycle of *Ancylostoma*.

Fig. 13.51 *Ancylostoma duodenale*. Electron micrograph showing the ventral teeth. From Gibbons LM. SEM guide to the morphology of nematode parasites of vertebrates. Farnham Royal, Slough: Commonwealth Agricultural Bureau International; 1986.

Hookworm infection is a leading cause of anaemia in the tropics and subtropics. *A. duodenale* is endemic in the Far East and Mediterranean coastal regions, and is also present in Africa, while *N. americanus* is endemic in West, East and Central Africa, and Central and South America, as well as in the Far East.

### Clinical features

An allergic dermatitis, usually on the feet (ground itch), may be experienced at the time of infection. The passage of the larvae through the lungs in a heavy infection causes a paroxysmal cough with blood-stained sputum, associated with patchy pulmonary consolidation and eosinophilia. When the worms reach the small intestine, vomiting and epigastric pain resembling peptic ulcer disease may occur. Sometimes, frequent loose stools are passed. The degree of iron and protein deficiency depends on the worm burden, patient nutrition and iron stores. Anaemia with high-output cardiac failure may result. The mental and physical development of children may be delayed in severe infection.

### Investigations

There is eosinophilia. The characteristic ovum can be recognised in the stool. If hookworms are present in numbers sufficient to cause anaemia, faecal occult blood testing will be positive.

### Management

A single dose of albendazole (400 mg) is the treatment of choice. Alternatively, mebendazole 100 mg twice daily for 3 days may be used. Anaemia and heart failure associated with hookworm infection respond well to oral iron, even when severe; blood transfusion is rarely required.

### Strongyloidiasis

*Strongyloides stercoralis* is a small nematode (2 mm × 0.4 mm) that parasitises the mucosa of the upper part of the small intestine, often in large numbers, causing persistent eosinophilia. The eggs hatch in the bowel but only larvae are passed in the faeces. In moist soil, they moult and become the infective filariform larvae. After penetrating human skin, they undergo a development cycle similar to that of hookworms, except that the female worms burrow into the intestinal mucosa and submucosa. Some larvae in the intestine may develop into filariform larvae, which may then penetrate the mucosa or the perianal skin and lead to autoinfection and persistent infection. Patients with *Strongyloides* infection persisting for more than 35 years have been described. Strongyloidiasis occurs in the tropics and subtropics, and is especially prevalent in the Far East.

### Clinical features

These are shown in Box 13.61. The classic triad of symptoms consists of abdominal pain, diarrhoea and urticaria. Cutaneous manifestations, either urticaria or larva currens (a highly characteristic pruritic, elevated, erythematous lesion, rapidly advancing along the course of larval migration), are characteristic and occur in 66% of patients.

#### 13.61 Clinical features of strongyloidiasis

##### Penetration of skin by infective larvae

- Itchy rash

##### Presence of worms in gut

- Abdominal pain, diarrhoea, steatorrhoea, weight loss

##### Allergic phenomena

- Urticarial plaques and papules, wheezing, arthralgia

##### Autoinfection

- Transient itchy, linear, urticarial weals across abdomen and buttocks (larva currens)

##### Systemic (super-)infection

- Diarrhoea, pneumonia, meningoenzephalitis, death

Systemic strongyloidiasis (the *Strongyloides* hyperinfection syndrome), with dissemination of larvae throughout the body, occurs with immune suppression (HIV or HTLV-1 infection, steroid or immunosuppressant treatment). Patients present with severe, generalised abdominal pain, abdominal distension and shock. Massive larval invasion of the lungs causes cough, wheeze and dyspnoea; cerebral involvement has manifestations ranging from subtle neurological signs to coma. Gram-negative sepsis frequently results.

### Investigations

There is eosinophilia. Serology (ELISA) is helpful but definitive diagnosis requires microscopic examination of faeces for motile rhabditiiform larvae; excretion is intermittent and so repeated examinations are necessary. Larvae may be found in jejunal aspirates or can also be cultured from faeces. PCR can be used for greater specificity and sensitivity.

### Management

A course of two doses of ivermectin (200 µg/kg), administered on successive days, is effective. Alternatively, albendazole is given orally (15 mg/kg twice daily for 3 days). A second course may be required. For the *Strongyloides* hyperinfection syndrome, ivermectin is given at 200 µg/kg for 5–7 days.

## Ascaris lumbricoides (roundworm)

This pale yellow nematode is 20–35 cm long and the largest of the intestinal nematodes. Humans are infected by eating food contaminated with mature ova. *Ascaris* larvae hatch in the duodenum, migrate through the lungs, ascend the bronchial tree, are swallowed and mature in the small intestine. This tissue migration can provoke both local and general hypersensitivity reactions, with pneumonitis, eosinophilic granulomas, wheezing and urticaria.

### Clinical features

Intestinal ascariasis causes symptoms ranging from vague abdominal pain to malnutrition. The large size of the adult worm and its tendency to aggregate and migrate result in obstructive complications. Tropical and subtropical areas are endemic for ascariasis, and here it causes up to 35% of all intestinal obstructions, most commonly in the terminal ileum. Obstruction can be complicated further by intussusception, volvulus, haemorrhagic infarction and perforation. Other complications include blockage of the bile or pancreatic duct and obstruction of the appendix by adult worms. Ascariasis in non-endemic areas has been associated with pig husbandry and may be caused by *Ascaris suum*, which is indistinguishable from *A. lumbricoides*.

### Investigations

The diagnosis is made microscopically by finding ova in the faeces. Adult worms are frequently expelled rectally or orally. Occasionally, the worms are demonstrated radiographically by a barium examination. There is eosinophilia.

### Management

A single dose of albendazole (400 mg), pyrantel pamoate (11 mg/kg; maximum 1 g), or ivermectin (150–200 µg/kg), or alternatively mebendazole (100 mg twice daily for 3 days) treats intestinal ascariasis. Patients should be warned that they might expel numerous whole, large worms. Obstruction due to ascariasis should be treated with nasogastric suction, piperazine and intravenous fluids. Complete intestinal obstruction and its complications require urgent surgical intervention.

### Prevention

Community chemotherapy programmes reduce *Ascaris* infection. The whole community can be treated every 3 months for several years. Alternatively treatment targets schoolchildren to lower the prevalence of ascariasis in the community.

## Enterobius vermicularis (threadworm, pinworm)

This helminth is common worldwide and affects mainly children. After the ova are swallowed, development takes place in the small intestine but the adult worms are found chiefly in the colon.

### Clinical features

The female lays ova around the anus, causing intense itching, especially at night. The ova are carried to the mouth on the fingers and so reinfection or human-to-human infection occurs (Fig. 13.52). In females, the genitalia may be involved. The adult worms may be seen moving on the buttocks or in the stool.

### Investigations

Ova are detected in stool samples or by applying the adhesive surface of cellophane tape to the perianal skin in the morning. This is then examined on a glass slide under the microscope. A perianal swab, moistened with saline, also allows diagnosis.

### Management

A single dose of mebendazole (100 mg), albendazole (400 mg), pyrantel pamoate (11 mg/kg) or piperazine (4 g) treats infection and is repeated after 2 weeks to control auto-reinfection. If infection recurs in a family, each member should be treated. All nightclothes and bed linen are laundered during treatment. Fingernails must be kept short and hands washed carefully before meals. Subsequent therapy is reserved for family members with recurrent infection.

## Trichuris trichiura (whipworm)

Whipworm infections are common worldwide with poor hygiene. Infection follows ingestion of earth or food contaminated with ova, which have become infective after lying for 3 weeks or more in moist soil. The adult worm is 3–5 cm long and has a coiled anterior end resembling a whip. Whipworms inhabit the caecum, lower ileum, appendix, colon and anal canal. There are usually no symptoms, but intense infections in children may cause persistent diarrhoea or rectal prolapse, and growth retardation. The diagnosis is readily made by identifying ova in faeces. Treatment is with mebendazole in doses of 100 mg twice daily or albendazole 400 mg daily for 3 days for patients with light infections, and for 5–7 days for those with heavy infections.

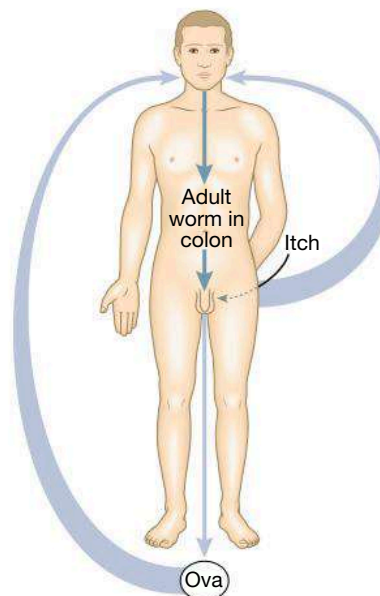

Fig. 13.52 Threadworm. Life cycle of *Enterobius vermicularis*.

## Tissue-dwelling human nematodes

Filarial worms are tissue-dwelling nematodes. The larval stages are inoculated by biting mosquitoes or flies, each specific to a particular filarial species. The larvae develop into adult worms (2–50 cm long), which, after mating, produce millions of microfilariae (170–320 µm long) that migrate in blood or skin. The life cycle is completed when the vector takes up microfilariae by biting humans. In the insect, ingested microfilariae develop into infective larvae for inoculation in humans, normally the only host.

Disease is due to the host's immune response to the worms (both adult and microfilariae), particularly dying worms, and its pattern and severity vary with the site and stage of each species (Box 13.62). The worms are long-lived: microfilariae survive 2–3 years and adult worms 10–15 years. The infections are chronic and worst in individuals constantly reinfected.

### Lymphatic filariasis

The filarial worms *Wuchereria bancrofti* and *Brugia malayi* infect approximately 120 million people globally whose features range from subclinical infection to hydrocele and elephantiasis.

*W. bancrofti* is usually transmitted by night-biting culicine or anopheline mosquitoes (Fig. 13.53). The adult worms, 4–10 cm in length, live in the lymphatics, and the females produce microfilariae that circulate in large numbers in the peripheral blood, usually at night. The infection is widespread in tropical Africa, on the North African coast, in coastal areas of Asia, Indonesia and northern Australia, the South Pacific islands, the West Indies and also in North and South America.

*B. malayi* usually causes less severe disease than *W. bancrofti* and is transmitted by *Mansonia* or *Anopheles* mosquitoes in Indonesia, Borneo, Malaysia, Vietnam, South China, South India and Sri Lanka.

### Pathology

Toxins released by adult worms cause lymphangiectasia; this dilatation of the lymphatic vessels leads to lymphatic dysfunction and the chronic clinical manifestations of lymphatic filariasis, lymphoedema and hydrocele. Death of the adult worm results in acute filarial lymphangitis. The filariae are symbiotically infected with rickettsia-like bacteria (*Wolbachia* spp.), and lipopolysaccharide released from *Wolbachia* triggers inflammation. Lymphatic obstruction persists after death of the adult worm. Secondary bacterial infections cause tissue destruction.

### Clinical features

Acute filarial lymphangitis presents with fever, pain, tenderness and erythema along the course of inflamed lymphatic vessels. Inflammation of the spermatic cord, epididymis and testis is common. Episodes last a few days but may recur several times a year. Temporary oedema becomes more persistent and regional lymph nodes enlarge. Progressive enlargement, coarsening, corrugation, fissuring and bacterial infection of the skin and subcutaneous tissue develop gradually, causing irreversible 'elephantiasis'. The scrotum may reach an enormous size. Chyluria and chylous effusions are milky and opalescent; on standing, fat globules rise to the top.

Acute lymphatic manifestations of filariasis must be differentiated from thrombophlebitis and infection. Oedema and lymphatic obstructive changes must be distinguished from congestive cardiac failure, malignancy, trauma and idiopathic abnormalities of the lymphatic system. Silicates absorbed from volcanic soil can also cause elephantiasis (podoconiosis).

Tropical pulmonary eosinophilia is a complication, and is the result of the host response to microfilariae. It is seen mainly in India, due to microfilariae trapped in the pulmonary capillaries that are destroyed by allergic inflammation. Patients present with paroxysmal cough, wheeze and fever. If untreated, this may progress to debilitating chronic interstitial lung disease.

### 13.62 Pathogenicity of filarial infections depending on site and stage of worms

Worm species	Adult worm	Microfilariae
<i>Wuchereria bancrofti</i> and <i>Brugia malayi</i>	Lymphatic vessels <sup>+++</sup>	Blood <sup>-</sup> Pulmonary capillaries <sup>++</sup>
<i>Loa loa</i>	Subcutaneous <sup>+</sup>	Blood <sup>+</sup>
<i>Onchocerca volvulus</i>	Subcutaneous <sup>+</sup>	Skin <sup>+++</sup> Eye <sup>+++</sup>
<i>Mansonella perstans</i>	Retroperitoneal <sup>-</sup>	Blood <sup>-</sup>
<i>Mansonella streptocerca</i>	Skin <sup>+</sup>	Skin <sup>++</sup>

(+++ severe; ++ moderate; + mild; - rarely pathogenic)

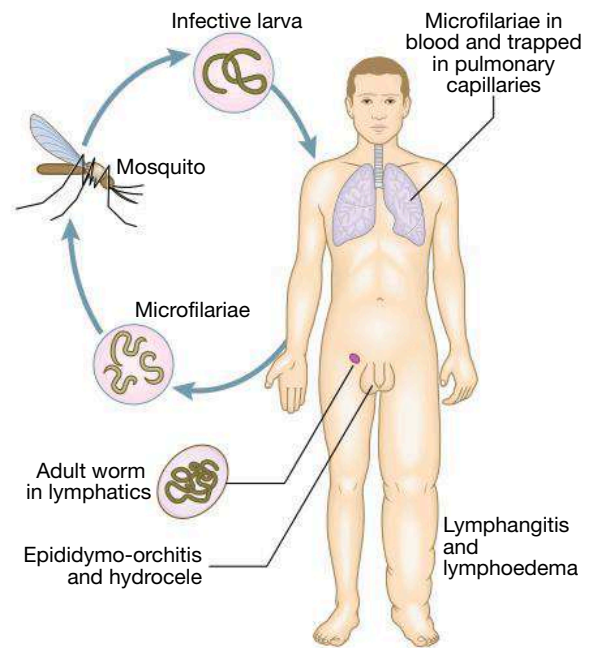

Fig. 13.53 *Wuchereria bancrofti* and *Brugia malayi*. Life cycle of organisms and pathogenesis of lymphatic filariasis.

### Investigations

Early in filariasis lymphangitis is a clinical diagnosis, supported by eosinophilia and sometimes by positive filarial serology. Filarial infections cause the highest eosinophil counts of all helminthic infections.

Microfilariae can be found in the peripheral blood at night; motile in a wet blood film or detected by microfiltration in lysed blood. They are usually present in hydrocele fluid, which may occasionally yield an adult filaria. By the time elephantiasis develops, microfilariae become difficult to find. Calcified filariae may sometimes be demonstrable by radiography. Movement of adult worms can be seen on scrotal ultrasound. PCR-based tests for detection of *W. bancrofti* and *B. malayi* DNA from blood have been developed.

Indirect fluorescence and ELISA detect antibodies in over 95% of active cases and 70% of established elephantiasis. The test becomes negative 1–2 years after cure. Serological tests cannot distinguish the different filarial infections. Highly sensitive and specific, commercially available, immunochromatographic card tests detect circulating *W. bancrofti* antigen using finger-prick blood samples taken at any time of the day.

In tropical pulmonary eosinophilia, serology is strongly positive and IgE levels are massively elevated but circulating microfilariae are not found. The chest X-ray shows miliary changes or mottled opacities. Pulmonary function tests show a restrictive picture.

## Management

Treatment is aimed at halting and reversing disease progression. Diethylcarbamazine (DEC, 2mg/kg orally 3 times daily for 21 days, or 6mg/kg as a single dose) kills microfilariae and adult worms. Most adverse effects seen with DEC treatment are due to the host response to dying microfilariae, which is directly proportional to the microfilarial load. The main symptoms are fever, headache, nausea, vomiting, arthralgia and prostration, usually within 24–36 hours of the first dose of DEC. Antihistamines or glucocorticoids treat these allergic phenomena. Combining albendazole (400mg) with ivermectin (200µg/kg) in a single dose, with or without DEC (300mg), is also highly effective in clearing the parasites. Treatment of *Wolbachia* with doxycycline (200mg/day) for 4–8 weeks provides additional benefit by eliminating the bacteria; this leads to interruption of parasite embryogenesis. For tropical pulmonary eosinophilia, DEC for 14 days is the treatment of choice.

## Co-infections

Patients co-infected with lymphatic filariasis and onchocerciasis with eye involvement should be treated with doxycycline before ivermectin. Co-infection with lymphatic filariasis and loiasis depends on the *Loa loa* microfilarial load. If high ivermectin, doxycycline or albendazole should be given first before DEC to reduce microfilarial load as DEC can result in severe encephalitis/shock.

## Chronic lymphatic pathology

Active management of chronic lymphatic pathology can alleviate symptoms. Patients should be taught meticulous skin care for lymphoedema to prevent secondary bacterial and fungal infections. Tight bandaging, massage and bed rest with elevation of the affected limb help to control the lymphoedema. Prompt diagnosis and antibiotic therapy of bacterial cellulitis prevent further lymphatic damage and worsening of existing elephantiasis. Plastic surgery to remove excess tissue may offer relief in established elephantiasis but without establishment of new lymphatic drainage recurrence is likely. Hydroceles and chyluria can be repaired surgically.

## Prevention

Treatment of the whole population (mass drug administration, MDA) in endemic areas with annual single-dose DEC (6mg/kg), either alone or in combination with albendazole and ivermectin (triple drugs), can reduce filarial transmission. MDA should be combined with mosquito control programmes.

## Loiasis

Loiasis is caused by infection with the filaria *Loa loa*. The disease is endemic in forested and swampy parts of Western and Central Africa. The adult worms, 3–7 cm × 4 mm, chiefly parasitise the subcutaneous tissue of humans, releasing larval microfilariae into the peripheral blood in the daytime. The vector is *Chrysops*, a forest-dwelling, day-biting fly.

The host response to *Loa loa* is usually absent or mild. From time to time a short-lived, inflammatory, oedematous swelling (a Calabar swelling) is produced around an adult worm. Heavy infections, especially when treated, may cause encephalitis.

## Clinical features

The infection is often symptomless. The incubation period ranges from 3 months to over a year. The first sign is usually a Calabar swelling: an irritating, tense, localised swelling that may be painful, especially if beside a joint. The swelling is generally on a limb; it measures a few centimetres in diameter but may be diffuse and extensive. It usually disappears after a few days but may persist for 2–3 weeks. Several swellings may appear at irregular intervals, often in adjacent sites. Sometimes, there is urticaria and pruritus elsewhere. Occasionally, a worm may be seen wriggling under the skin, especially that of an eyelid, and may cross the eye under the conjunctiva, taking many minutes to do so.

## Investigations

Diagnosis is by demonstrating microfilariae in blood taken during the day, but they may not always be found in patients with Calabar swellings. Antifilarial antibodies are positive in 95% of patients and there is massive eosinophilia. Occasionally, a calcified worm may be seen on X-ray.

## Management

DEC (see above) is curative, in a dose of 9–12mg/kg daily, continued for 21 days. Treatment may precipitate a severe ('Mazzotti') reaction in patients with a heavy microfilaraemia, characterised by fever, joint and muscle pain, and encephalitis; microfilaraemic patients should be given glucocorticoid cover.

## Prevention

Building houses away from trees and having dwellings wire-screened reduce infections. Protective clothing and insect repellents are also useful. DEC in a dose of 5mg/kg daily for 3 days each month is partially protective.

## Onchocerciasis (river blindness)

Onchocerciasis results from infection by the filarial *Onchocerca volvulus*. The infection is conveyed by flies of the genus *Simulium*, which breed in rapidly flowing, well-aerated water. Adult flies inflict painful bites during the day, both inside and outside houses. While feeding, they pick up the microfilariae, which mature into the infective larva and are transmitted to a new host in subsequent bites. Humans are the only known hosts (Fig. 13.54).

Onchocerciasis is endemic in sub-Saharan Africa, Yemen and a few foci in Central and South America. It is estimated that 21 million people are infected and 1 million have vision loss. Due to onchocerciasis, huge tracts of fertile land lie virtually untilled and individuals and communities are impoverished.

## Pathology

After inoculation of larvae by a bite, the worms mature in 2–4 months and live for up to 17 years in subcutaneous and connective tissues. At sites of trauma, over bony prominences and around joints, fibrosis may form nodules around adult worms, which otherwise cause no direct damage. Innumerable microfilariae, discharged by the female *O. volvulus*, move actively in these nodules and in the adjacent tissues. The microfilariae

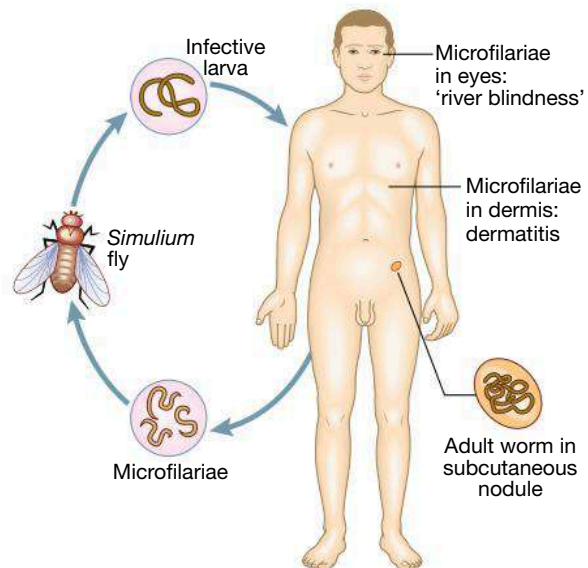

Fig. 13.54 *Onchocerca volvulus*. Life cycle of organism and pathogenesis of onchocerciasis.

are widely distributed in the skin and may invade the eye. Live microfilariae elicit little tissue reaction but dead ones may cause severe allergic inflammation, leading to hyaline necrosis and loss of collagen and elastin. Death of microfilariae in the eye causes inflammation and may lead to blindness.

### Clinical features

The infection may remain symptomless for months or years. The first symptom is usually itching, localised to one quadrant of the body and later becoming generalised and involving the eyes. Transient oedema of part or all of a limb is an early sign, followed by papular urticaria, spreading gradually from the site of infection. In dark skins the most common signs are papules excoriated by scratching, spotty hyperpigmentation from resolving inflammation, and chronic changes of a rough, thickened and wrinkled skin. Both infected and uninfected superficial lymph nodes enlarge and may hang down in folds of loose skin in the groin. Hydrocele, femoral hernias and scrotal elephantiasis can occur. Firm subcutaneous nodules  $\geq 1$  cm in diameter (onchocercomas) occur in chronic infection.

Eye disease is most common in highly endemic areas and is associated with chronic heavy infections and nodules on the head. Early manifestations include itching, lacrimation and conjunctival injection. These cause conjunctivitis; sclerosing keratitis with pannus formation; uveitis, which may lead to glaucoma and cataract; and, less commonly, chorioiditis and optic neuritis. Classically, 'snowflake' deposits are seen in the edges of the cornea.

### Investigations

The finding of nodules or characteristic lesions of the skin or eyes in a patient from an endemic area, associated with eosinophilia, is suggestive. Skin snips or shavings, taken with a corneoscleral punch or scalpel blade from calf, buttock and shoulder, are placed in saline under a cover slip on a microscope slide and examined after 4 hours. Microfilariae are seen wriggling free in all but the lightest infections. Slit-lamp examination may reveal microfilariae moving in the anterior chamber of the eye or trapped in the cornea. An excised nodule may reveal a coiled, thread-like adult worm.

Filarial antibodies are positive in up to 95% of patients. Rapid strip tests to detect antibody or antigen are under clinical evaluation. When there is a strong suspicion of onchocerciasis but tests are negative, a provocative Mazzotti test, in which administration of 0.5–1.0 mg/kg of DEC exacerbates pruritus or dermatitis, strongly suggests onchocerciasis. PCR, though highly sensitive and specific, is not available commercially.

### Management

Ivermectin is recommended, in a single dose of 100–200  $\mu$ g/kg, repeated several times at 3-monthly intervals to prevent relapses. It kills microfilariae and has minimal toxicity. In the rare event of a severe reaction causing oedema or postural hypotension, prednisolone 20–30 mg may be given daily for 2 or 3 days. Ivermectin has little macrofilaricidal effect so that, 1 year after ivermectin treatment, skin microfilarial densities regain at least 20% of pre-treatment levels; repeated treatments are required for the lifespan of the adult worm. Eradication of *Wolbachia* with doxycycline (100 mg daily for 6 weeks) prevents worm reproduction.

### Prevention

Mass treatment with ivermectin reduces community morbidity and slows the progression of eye disease but it does not clear worm infection. *Simulium* can be destroyed in its larval stage by the application of insecticide to streams. Long trousers, skirts and sleeves discourage the fly from biting.

## Dracunculiasis (Guinea worm)

Infestation with the Guinea worm *Dracunculus medinensis* manifests when the female worm, over a metre long, emerges from the skin. Humans are infected by ingesting a small crustacean, *Cyclops*, which inhabits wells and ponds, and contains the infective larval stage of the worm. Global programmes have almost eradicated this disease.

However, recent findings of dracunculiasis in animals pose a challenge to eradication efforts. This is especially the case for dogs in Chad, as 48 of 54 cases in 2019 worldwide were in Chad.

### Management and prevention

Traditionally, the protruding worm is extracted by winding it out gently over several days on a matchstick. The worm must never be broken. Antibiotics for secondary infection and prophylaxis of tetanus are also required.

The global eradication campaign aims to provide clean drinking water and eradicate water fleas from drinking water by simple filtration of water through a plastic mesh filter and chemical treatment of water supplies.

## Other filariases

### *Mansonella perstans*

This filarial worm is transmitted by the midges *Culicoides austeni* and *C. grahmi*. It is common throughout equatorial Africa, as far south as Zambia, and also in Trinidad and parts of northern and eastern South America.

*M. perstans* has never been proven to cause disease but it may be responsible for a persistent eosinophilia and occasional allergic manifestations. *M. perstans* is resistant to ivermectin and DEC, however, anti-*Wolbachia* treatment (doxycycline 200 mg daily for 6 weeks) can cure this infection.

### *Dirofilaria immitis*

This dog heartworm infects humans, causing skin and lung lesions. It is not uncommon in the USA, Japan and Australia.

## Zoonotic nematodes

### Trichinosis (trichinellosis)

*Trichinella spiralis* is a nematode that parasitises rats and pigs, and is transmitted to humans by ingestion of partially cooked infected pork, particularly sausage or ham, or occasionally by bear meat. Symptoms result from invasion of intestinal submucosa by ingested larvae, which develop into adult worms, and the secondary invasion of striated muscle by fresh larvae produced by these adult worms. Outbreaks have occurred in countries where pork is eaten.

### Clinical features

The clinical features of trichinosis are determined by the larval numbers. A light infection with a few worms may be asymptomatic; a heavy infection causes nausea and diarrhoea 24–48 hours after the infected meal. A few days later, the symptoms associated with larval invasion predominate: there is fever and oedema of the face, eyelids and conjunctivae; invasion of the diaphragm may cause pain, cough and dyspnoea; and involvement of the muscles of the limbs, chest and mouth causes stiffness, pain and tenderness in affected muscles. Larval migration may cause acute myocarditis and encephalitis. Eosinophilia, which can be very high, is observed after 10 days. An intense infection may prove fatal but those who survive recover completely.

### Investigations

Frequently, people who have eaten infected pork from a common source develop symptoms at about the same time. Biopsy from the deltoid or gastrocnemius muscle after the third week of symptoms may reveal encysted larvae. Serological tests are also helpful.

### Management

Treatment is with albendazole (400 mg twice daily for 8–14 days) or mebendazole (200–400 mg three times daily for 3 days, followed by 400–500 mg three times daily for 10 days). Treatment commenced early in infection kills newly formed adult worms in the submucosa and reduces the number of larvae reaching the muscles. Glucocorticoids are necessary to control the serious effects of acute inflammation.

## Anisakiasis (herring worm)

This infection is caused by the larvae of a fish nematode (*Anisakis simplex* or *Pseudoterranova decipiens*) and is associated with consumption of under-cooked fish or squid. The parasite cannot complete its life cycle in humans but larval ingestion is associated with pharyngeal tingling, abdominal pain, diarrhoea and vomiting. Diagnosis is made by identification of the larva by patients or endoscopists, and albendazole (400 mg twice a day for 5 days) treats larvae that are not manually removed.

## Cutaneous larva migrans

Cutaneous larva migrans (CLM) is the most common linear lesion seen in travellers (Fig. 13.55). Intensely pruritic, linear, serpiginous lesions result from the larval migration of the dog hookworm (*Ancylostoma caninum*). The track moves across the skin at a rate of 2–3 cm/day. This contrasts with the fast-moving transient rash of *Strongyloides*. Although the larvae of dog hookworms frequently infect humans, they do not usually develop into the adult form. The most common site for CLM is the foot but elbows, breasts and buttocks may be affected. Most patients with CLM have recently visited a beach where the affected part was exposed. The diagnosis is clinical. Treatment may be local with 12-hourly application of 15% thiabendazole cream, or systemic with a single dose of albendazole (400 mg) or ivermectin (150–200 µg/kg).

## Angiostrongylus cantonensis

The rat lungworm infects humans in Asia and the Pacific basin, via ingestion of infected snails or contaminated water. It causes eosinophilic meningitis. The role of combination therapy with glucocorticoids and albendazole remains controversial.

## Gnathostomiasis

Gnathostomiasis occurs predominantly in South-east Asia and is due to *Gnathostoma spinigerum*. It also occurs in other parts of Asia, Central and South America, and Africa. Humans are infected by the larvae from intermediate hosts (raw or under-cooked freshwater fish, shrimps and frogs) and are not definitive hosts, so the life cycle is incomplete. Pruritic, painful, migratory nodules appear 3–4 weeks after ingestion due to larval migration. Complications include cough, visual disturbance, eosinophilic meningitis or encephalitis. Serology confirms diagnosis and the preferred

**Fig. 13.55** Cutaneous larva migrans. Courtesy of Dr Ravi Gowda, Royal Hallamshire Hospital, Sheffield.

treatment is albendazole (400 mg twice daily) for 21 days, but its role in visual or neurological disease is uncertain as it may increase larval migration.

## Trematodes (flukes)

These leaf-shaped worms are parasitic to humans and animals. Their complex life cycles may involve one or more intermediate hosts, often freshwater molluscs.

## Schistosomiasis

Schistosomiasis is a major cause of morbidity in the tropics. The species commonly causing disease in humans are: *Schistosoma haematobium*, *S. mansoni*, *S. japonicum*, *S. mekongi* and *S. intercalatum*. *S. haematobium* is sometimes called bilharzia or bilharziasis. Schistosome eggs have been found in Egyptian mummies.

The life cycle is shown in Figure 13.56A. The ovum is passed in the urine or faeces of infected individuals and gains access to fresh water, where the ciliated miracidium is liberated; it enters its intermediate host, a species of freshwater snail, and multiplies. Large numbers of fork-tailed cercariae are then liberated into the water, where they may survive for 2–3 days. Cercariae can penetrate the skin or the mucous membrane of the mouth of humans. They transform into schistosomulae and moult as they pass through the lungs; then they are carried by the blood stream to the liver, and so to the portal vein, where they mature. The male worm is up to 20 mm in length and the slenderer cylindrical female, usually enfolded longitudinally by the male, is longer (Fig. 13.56B). Within 4–6 weeks of infection, they migrate to the venules draining the pelvic viscera, where the females deposit ova.

### Pathology

The passage of eggs through mucosa and the granulomatous reaction to eggs deposited in tissues causes disease. The eggs of *S. haematobium* pass mainly through the bladder wall but may also involve the rectum, seminal vesicles, vagina, cervix and uterine tubes. *S. mansoni* and *S. japonicum* eggs pass mainly through the wall of the lower bowel or are carried to the liver. The most serious, although rare, site of ectopic egg deposition is the CNS. Granulomas are composed of macrophages, eosinophils, and epithelioid and giant cells around an ovum. Later, there is fibrosis and eggs calcify, which is often visible radiologically. Eggs of *S. haematobium* may leave the vesical plexus and be carried directly to the lung. Those of *S. mansoni* and *S. japonicum* may also reach the lungs after the development of portal hypertension and consequent portosystemic collateral circulation. Egg deposition in the pulmonary vasculature, and the resultant host response, can lead to pulmonary hypertension.

### Clinical features

Recent travellers, especially those overlanding through Africa, may present with allergic manifestations and eosinophilia; residents of schistosomiasis-endemic areas are more likely to present with chronic urinary tract pathology or portal hypertension.

During early infection, there may be itching lasting 1–2 days at the site of cercarial penetration ('swimmer's itch'). After a symptom-free period of 3–5 weeks, acute schistosomiasis (Katayama syndrome) may present with allergic manifestations: urticaria, fever, muscle aches, abdominal pain, headaches, cough and sweating. On examination, hepatomegaly, splenomegaly, lymphadenopathy and pneumonia may be present. These allergic phenomena may be severe in infections with *S. mansoni* and *S. japonicum*, but are rare with *S. haematobium*. The features subside after 1–2 weeks.

Chronic schistosomiasis is due to egg deposition and occurs months to years after infection. The symptoms and signs depend on the intensity of infection and the species of infecting schistosome (Box 13.63).

### *Schistosoma haematobium*

Humans are the only natural hosts of *S. haematobium*, which is highly endemic in Egypt and East Africa, and occurs throughout Africa and the

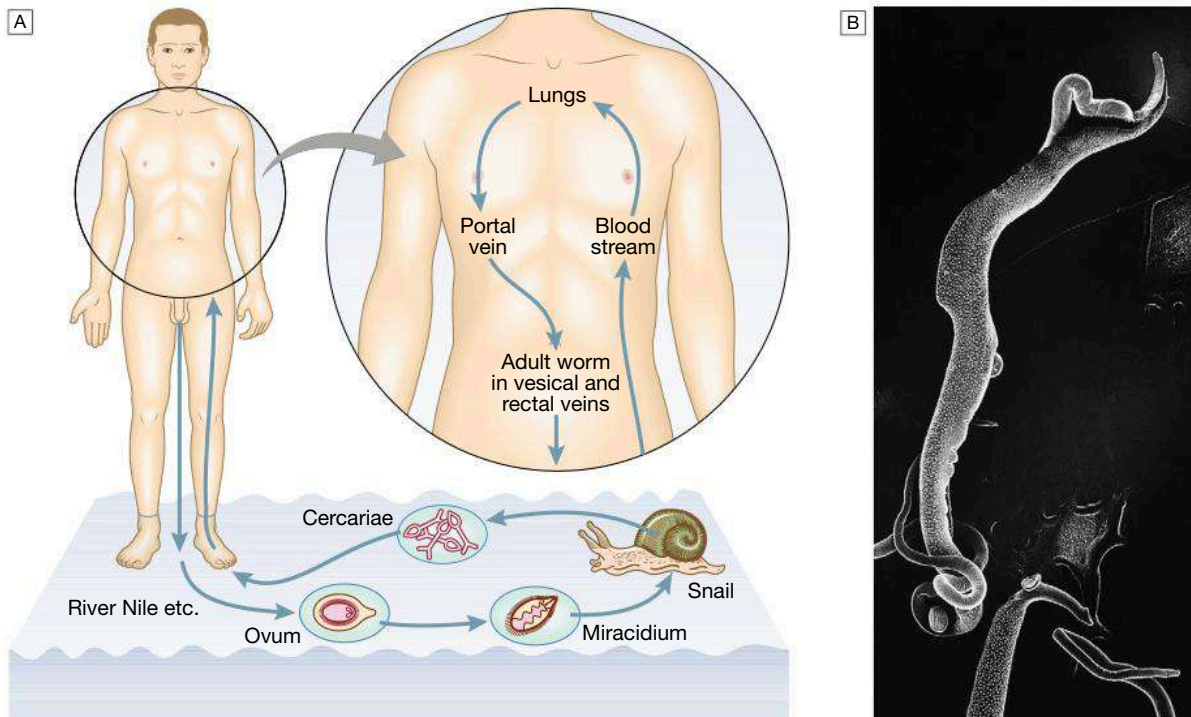

Fig. 13.56 *Schistosoma*. **A** Life cycle. **B** Scanning electron micrograph of adult schistosome worms, showing the larger male worm embracing the thinner female.

13.63 Pathogenesis of schistosomiasis		
Time	<i>Schistosoma haematobium</i>	<i>S. mansoni</i> and <i>S. japonicum</i>
<b>Cercarial penetration</b>		
Days	Papular dermatitis at site of penetration	As for <i>S. haematobium</i>
<b>Larval migration and maturation</b>		
Weeks	Pneumonitis, myositis, hepatitis, fever, 'serum sickness', eosinophilia, seroconversion	As for <i>S. haematobium</i>
<b>Early egg deposition</b>		
Months	Cystitis, haematuria	Colitis, granulomatous hepatitis, acute portal hypertension
	Ectopic granulomatous lesions: skin, CNS etc. Immune complex glomerulonephritis	As for <i>S. haematobium</i>
<b>Late egg deposition</b>		
Years	Fibrosis and calcification of ureters, bladder: bacterial infection, calculi, hydronephrosis, carcinoma	Colonic polyposis and strictures, periportal fibrosis, portal hypertension
	Pulmonary granulomas and pulmonary hypertension	As for <i>S. haematobium</i>

Middle East (Fig. 13.57). Infection can be acquired after a brief exposure, such as swimming in freshwater lakes in Africa.

Painless terminal haematuria is usually the first and most common symptom. Frequency of micturition follows, due to bladder neck

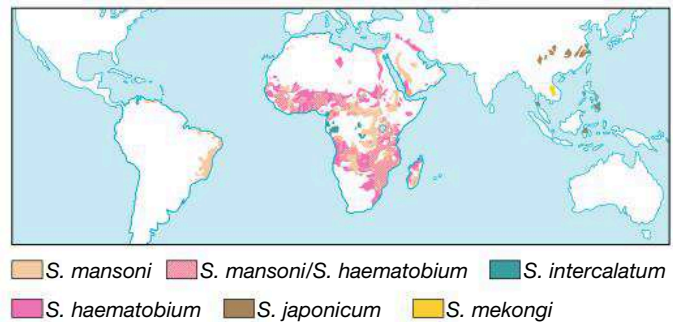

Fig. 13.57 Geographical distribution of schistosomiasis. From Gryseels et al., *Lancet* 2006; 368:1106–1118.

obstruction. Later, frequent urinary tract infections, bladder or ureteric stones, hydronephrosis and ultimately renal failure with a contracted calcified bladder may occur. Pain is often felt in the iliac fossa or in the loin, and radiates to the groin. In several endemic areas, there is a strong epidemiological association of *S. haematobium* infection with squamous cell carcinoma of the bladder. Disease of the seminal vesicles may lead to haematospermia. Females may develop schistosomal papillomas of the vulva, and schistosomal lesions of the cervix may be mistaken for cancer. Intestinal symptoms may follow involvement of the bowel wall. Ectopic worms cause skin or spinal cord lesions.

The severity of *S. haematobium* infection varies greatly; light infections are often asymptomatic. However, as adult worms can live for 20 years or more and lesions may progress, these patients should always be treated.

#### *Schistosoma mansoni*

*S. mansoni* is endemic throughout Africa, the Middle East, Venezuela, Brazil and the Caribbean (see Fig. 13.57).

Characteristic symptoms begin from 2 months after infection. They may be minimal (e.g. malaise) or consist of abdominal pain and frequent stools that contain blood-stained mucus. With severe advanced disease,

increased discomfort from rectal polyps may be experienced. The early hepatomegaly is reversible but portal hypertension may cause massive splenomegaly, fatal haematemesis from oesophageal varices, or progressive ascites. Liver function is initially preserved because the pathology is fibrotic rather than cirrhotic. *S. mansoni* and other schistosome infections predispose to the carriage of *Salmonella*, in part because *Salmonella* may attach to the schistosomes and in part because shared antigens on schistosomes may induce immunological tolerance to *Salmonella*.

### *Schistosoma japonicum*, *S. mekongi* and *S. intercalatum*

In addition to humans, the adult worm of *S. japonicum* infects the dog, rat, field mouse, water buffalo, ox, cat, pig, horse and sheep. Although other *Schistosoma* spp. can infect species other than humans, the non-human reservoir seems to be particularly important only in transmission for *S. japonicum*. *S. japonicum* is prevalent in the Yellow River and Yangtze–Jiang basins in China, where the infection is a major public health problem. It also has a focal distribution in the Philippines, Indonesia and Thailand (see Fig. 13.57). The related *S. mekongi* occurs in Laos, Thailand and Myanmar, and *S. intercalatum* in West and Central Africa.

The pathology of *S. japonicum* is similar to that of *S. mansoni*, but as this worm produces more eggs, the lesions tend to be more extensive and widespread. The clinical features resemble those of severe infection with *S. mansoni*, with added neurological features. The small and large bowel may be affected, and hepatic fibrosis with splenic enlargement is usual. Deposition of eggs or worms in the CNS, especially in the brain or spinal cord, causes symptoms in about 5% of infections, notably epilepsy, blindness, hemiplegia or paraplegia.

### Investigations

There is marked eosinophilia. Serological tests (ELISA) are useful as screening tests but remain positive after treatment.

In *S. haematobium* infection, dipstick urine testing shows blood and albumin. The eggs can be found by microscopic examination of the centrifuged deposit of terminal stream urine (Fig. 13.58). Ultrasound assesses the urinary tract; bladder wall thickening, hydronephrosis and bladder calcification can be detected. Cystoscopy reveals 'sandy' patches, bleeding mucosa and later distortion.

In a heavy infection with *S. mansoni* or *S. japonicum*, the characteristic egg with its lateral spine can usually be found in the stool. When the infection is light or of long duration, a rectal biopsy can be examined. Sigmoidoscopy may show inflammation or bleeding. Biopsies should be examined for ova. PCR, though highly sensitive and specific, is not widely available.

### Management

Therapy aims to kill the adult schistosomes and stop egg-laying. Praziquantel (20mg/kg orally twice daily for 1 day) is the drug of choice for all forms of schistosomiasis except *S. japonicum* and *S. mekongi*, for which 20mg/kg for 3 doses is recommended. The drug produces parasitological cure in 80% of treated individuals and over 90% reduction in egg counts in the remainder. Side-effects are uncommon but include nausea and abdominal pain. Praziquantel therapy in early infection reverses hepatomegaly, bladder wall thickening and granulomas.

Surgery may be required to deal with residual lesions such as ureteric stricture, small fibrotic urinary bladders, or granulomatous masses in the brain or spinal cord. Removal of rectal papillomas by diathermy or by other means may provide symptomatic relief.

### Prevention

No single means of controlling schistosomiasis has been established to date. The life cycle is terminated if fresh water containing the snail host is not contaminated by ova-containing urine or faeces. The provision of latrines and of a safe water supply, however, remains challenging in rural areas throughout the tropics. Furthermore, *S. japonicum* has multiple hosts besides humans, therefore latrines would have little impact. Population mass treatment annually helps prevent *S. haematobium* and

Fig. 13.58 Ova of *Schistosoma haematobium* in urine. Note the terminal spike.

*S. mansoni* infection but so far has had little success with *S. japonicum*. Targeting the intermediate host, the snail, is problematic and has not, on its own, proved successful. For personal protection, contact with infected water must be avoided.

### Liver flukes

Liver flukes infect at least 20 million people and remain public health priorities in endemic areas. Clinical symptoms are abdominal pain, hepatomegaly and relapsing cholangitis. *Clonorchis sinensis* and *Opisthorchis felinus* are major aetiological agents of bile duct cancer. The three major liver flukes have similar life cycles and pathologies, as outlined in Box 13.64.

Other flukes of medical importance include lung and intestinal flukes (see Box 13.60).

### Cestodes (tapeworms)

Cestodes are ribbon-shaped worms that inhabit the intestinal tract. They have no alimentary system and absorb nutrients through the tegumental surface. The anterior end, or scolex, has suckers for attaching to the host. From the scolex, a series of progressively developing segments arise, the proglottides, which may continue to show active movements when shed. Cross-fertilisation takes place between segments. Ova, present in large numbers in mature proglottides, remain viable for weeks, and during this period they may be consumed by the intermediate host. Larvae liberated from the ingested ova pass into the tissues of the intermediate host, forming larval cysticerci.

Tapeworms cause two distinct patterns of disease: either intestinal infection or systemic cysticercosis (see Fig. 13.59). *Taenia saginata* (beef tapeworm), *Taenia asiatica* and *Diphyllobothrium latum* (fish tapeworm) cause only intestinal infection in humans, following ingestion of intermediate hosts. *Taenia solium* causes intestinal infection if a cysticercus-containing intermediate host is ingested, and cysticercosis (systemic infection from larval migration) if ova are ingested. *Echinococcus granulosus* (dog tapeworm) does not cause human intestinal infection, but causes hydatid disease (which is analogous to cysticercosis) following ingestion of ova and subsequent larval migration.

### Intestinal tapeworm

Humans acquire tapeworm by eating under-cooked beef infected with the larval stage of *T. saginata*, under-cooked pork containing the larval stage of *T. solium* or *T. asiatica*, or under-cooked freshwater fish containing larvae of *D. latum*. Usually, only one adult tapeworm is present in the gut but up to 10 have been reported. The ova of all the three *Taenia* are indistinguishable microscopically. However, examination of scolex

13.64 Diseases caused by flukes in the bile duct			
	Clonorchiasis	Opisthorchiasis	Fascioliasis
Parasite	<i>Clonorchis sinensis</i>	<i>Opisthorchis felineus</i>	<i>Fasciola hepatica</i>
Other mammalian hosts	Dogs, cats, pigs	Dogs, cats, foxes, pigs	Sheep, cattle
Mode of spread	Ova in faeces, water	As for <i>C. sinensis</i>	Ova in faeces on to wet pasture
1st intermediate host	Snails	Snails	Snails
2nd intermediate host	Freshwater fish	Freshwater fish	Encysts on vegetation
Geographical distribution	Far East, especially South China	Far East, especially North-east Thailand	Cosmopolitan, including UK
Pathology	<i>Escherichia coli</i> cholangitis, abscesses, biliary carcinoma	As for <i>C. sinensis</i>	Toxaemia, cholangitis, eosinophilia
Symptoms	Often symptom-free, recurrent jaundice	As for <i>C. sinensis</i>	Unexplained fever, tender liver, may be ectopic, e.g. subcutaneous fluke
Diagnosis	Ova in stool or duodenal aspirate	As for <i>C. sinensis</i>	As for <i>C. sinensis</i> , also serology
Prevention	Cook fish	Cook fish	Avoid contaminated watercress
Treatment	Praziquantel 25 mg/kg 3 times daily for 2 days	As for <i>C. sinensis</i> but for 1 day only	Triclabendazole 10 mg/kg single dose; repeat treatment may be required*

\*In the UK, available from the Hospital for Tropical Diseases, London.

and proglottides can differentiate them: *T. solium* has a rostellum and two rows of hooklets on the scolex, and discharges multiple proglottides (3–5) attached together with lower degrees of uterine branching (approximately 10); *T. saginata* has only four suckers in its scolex, and discharges single proglottids with greater uterine branching (up to 30); *T. asiatica* has a rostellum without hooks on its scolex and is difficult to differentiate from *T. saginata*, except that there are fewer uterine branches (16–21).

### *Taenia solium*

*T. solium*, the pork tapeworm, is common in central Europe, South Africa, South America and parts of Asia. It is smaller than *T. saginata*. The adult worm is found only in humans following the ingestion of pork containing cysticerci. Intestinal infection is treated with praziquantel (5–10 mg/kg) or niclosamide (2 g), both as a single dose, or alternatively with nitazoxanide (500 mg twice daily for 3 days). These are followed by a mild laxative (after 1–2 hours) to prevent retrograde intestinal autoinfection. Cooking pork well prevents intestinal infection. Great care must be taken while attending a patient harbouring an adult worm to avoid ingestion of ova or segments.

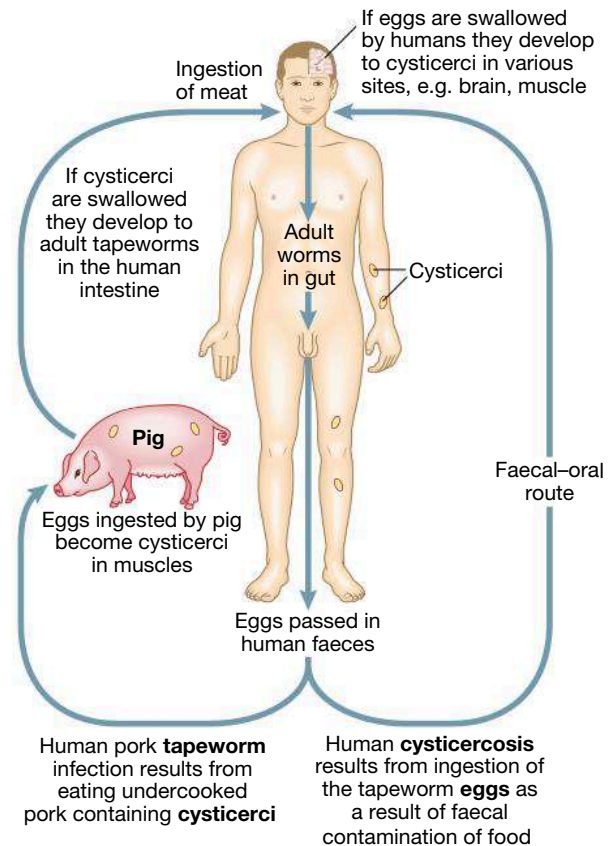

Fig. 13.59 Cysticercosis. Life cycle of *Taenia solium*.

### *Taenia saginata*

Infection with *T. saginata* occurs in all parts of the world. The adult worm may be several metres long and produces minimal intestinal upset in human beings, but identification of segments in the faeces or on under-clothing distresses patients. Ova may be found in the stool. Praziquantel is the drug of choice; niclosamide or nitazoxanide are alternatives. Prevention depends on efficient meat inspection and thorough cooking of beef.

### *Taenia asiatica*

*T. asiatica* is a newly recognised species of *Taenia*, restricted to Asia. It is acquired by eating uncooked meat or viscera of pigs. Clinical features and treatment are similar to those of *T. saginata*.

## Cysticercosis

Human cysticercosis is acquired by ingesting *T. solium* tapeworm ova, from either contaminated fingers or food (Fig. 13.59). The larvae are liberated from eggs in the stomach, penetrate the intestinal mucosa and are carried to many parts of the body, developing into cysticerci, 0.5–1 cm cysts that contain the head of a young worm. They do not grow further or migrate. Common locations are subcutaneous tissue, skeletal muscles and brain (Fig. 13.60).

### Clinical features

Superficial cysts can be palpated under the skin or mucosa as pea-like ovoid bodies, but cause few or no symptoms and eventually die and calcify.

Heavy brain infections, especially in children, may cause features of encephalitis. More commonly, however, cerebral signs do not occur until the larvae die, 5–20 years later. Epilepsy, including new-onset focal seizures, personality changes, staggering gait and signs of hydrocephalus, are the most common features.

**Fig. 13.60 Neurocysticercosis.** T2-weighted axial image of the brain showing multiple lesions of neurocysticercosis (arrows show the largest lesions).

### Investigations

Calcified cysts in muscles can be recognised radiologically. In the brain, however, less calcification takes place and larvae are only occasionally visible by plain X-ray; CT or magnetic resonance imaging (MRI) will usually show them. Epileptic fits starting in adult life suggest the possibility of cysticercosis if the patient has lived in or travelled to an endemic area. The subcutaneous tissue should be palpated and any nodule excised for histology. Radiological examination of the skeletal muscles may be helpful. Antibody detection is available for serodiagnosis.

### Management and prevention

Albendazole (15 mg/kg daily for a minimum of 8 days) is recommended for parenchymal neurocysticercosis. Praziquantel (50 mg/kg in 3 divided doses daily for 10 days) is another option. Prednisolone (10 mg 3 times daily) is also given for 14 days, starting 1 day before anti-cysticercosis therapy. Antiepileptic drugs are often prescribed until the reaction in the brain has subsided. Operative intervention is indicated for hydrocephalus. Studies from India and Peru suggest that most small, solitary cerebral cysts will resolve without treatment.

## ***Echinococcus granulosus* (*Taenia echinococcus*) and hydatid disease**

Dogs are the definitive hosts of the tiny tapeworm *E. granulosus*. The larval stage, a hydatid cyst, normally occurs in sheep, cattle, camels and other animals exposed to contaminated pastures or water. By handling a dog or drinking contaminated water, humans may ingest eggs (Fig. 13.61). The embryo is liberated from the ovum in the small intestine and invades the blood stream, spreading to the liver. The resultant cyst grows very slowly, sometimes intermittently. It is composed of an enveloping fibrous pericyst, laminated hyaline membrane (ectocyst) and inner germinal layers (endocyst) that give rise to daughter cysts, or a germinating cystic brood capsule in which larvae (protoscolices) develop. Over time, some cysts calcify and become non-viable. The disease is common in the Middle East, North and East Africa, Australia and Argentina. Foci of infection persist in the UK in rural Wales and Scotland. *E. multilocularis*, which has a cycle between foxes and voles, causes a similar but more severe infection, 'alveolar hydatid disease', which invades the liver like cancer.

### Clinical features

A hydatid cyst is typically acquired in childhood and, after growing for years, may cause site-specific pressure symptoms. In nearly 75% of patients the right lobe of the liver is invaded and contains a single cyst. In others, a cyst may be found in lung, bone, brain or elsewhere.

### Investigations

The diagnosis depends on the clinical, radiological and ultrasound findings in a patient that has close contact with dogs in an endemic area. Complement fixation and ELISA are positive in 70%–90% of patients.

### Management and prevention

Hydatid cysts should be excised wherever possible. Great care is taken to avoid spillage and cavities are sterilised with 0.5% silver nitrate or 2.7% sodium chloride. Albendazole (400 mg twice daily for 3 months) should also be used and is often combined with PAIR (percutaneous puncture, aspiration, injection of scolicedal agent and re-aspiration). Praziquantel (20 mg/kg twice daily for 14 days) also kills protoscolices perioperatively.

Prevention is difficult when there is a close association with dogs. Personal hygiene, satisfactory disposal of carcasses, meat inspection and deworming of dogs reduces disease prevalence.

## Other tapeworms

Other cestodes' adult or larval stages may infect humans. In sparganosis an immature worm develops, usually subcutaneously, as a result of eating or applying to the skin the secondary or tertiary intermediate host, such as frogs or snakes.

## Ectoparasites

Ectoparasites only interact with the outermost surfaces of the host; see also page 1093.

### Jiggers (tungiasis)

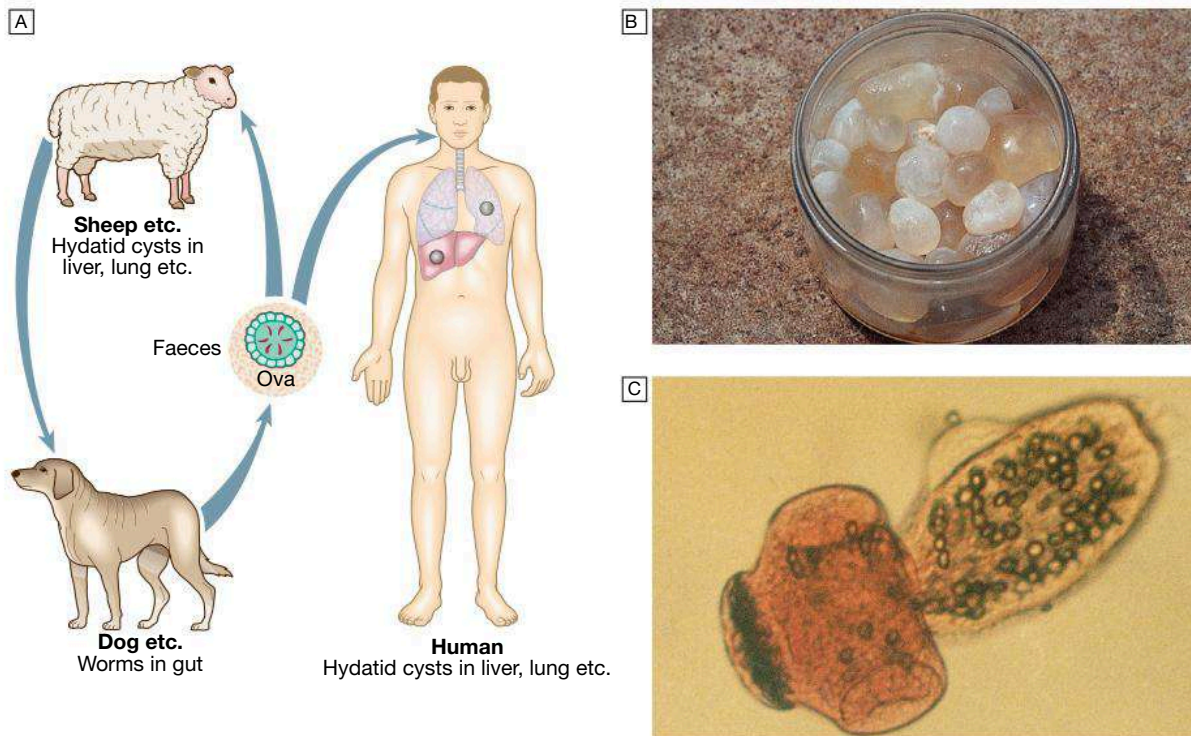

This is widespread in tropical America and Africa, and is caused by the sand flea *Tunga penetrans*. The pregnant flea burrows into the skin around toes and produces large numbers of eggs. The burrows are intensely irritating and the whole inflammatory nodule should be removed with a sterile needle. Secondary infection of lesions is common.

### Myiasis

Myiasis is due to skin infestation with larvae of the South American botfly, *Dermatobia hominis*, or the African tumbu fly, *Cordylobia anthropophaga*. The larvae develop in a subcutaneous space with a central sinus. This orifice is the air source for the larvae, and periodically the larval respiratory spiracles protrude through the sinus. Patients with myiasis feel movement within the larval burrow and can experience intermittent sharp, lancinating pains. Myiasis is diagnosed clinically and should be suspected with any furuncular lesion accompanied by pain and a crawling sensation in the skin. The larva may be suffocated by blocking the respiratory orifice with petroleum jelly and gently removing it with tweezers. Secondary infection of myiasis is rare and rapid healing follows removal of intact larvae.

## Fungal infections

Fungal infections, or mycoses, are classified as superficial, subcutaneous or systemic (deep), depending on the degree of tissue invasion.

**Fig. 13.61** Hydatid disease. **A** Life cycle of *Echinococcus granulosus*. **B** Daughter cysts removed at surgery. **C** Within the daughter cysts are the protoscolices.

**Fig. 13.62** Classification of medically important fungi. Fungal classification is based on simple morphological characteristics. *Pneumocystis jirovecii* is morphologically distinct from other fungi and does not fit into this classification. \*Although *Candida albicans* exists in a number of forms, including filamentous (hyphae and pseudohyphae), it is generally encountered in its yeast form so is classified in this category. Insets (dimorphic fungi) Courtesy of Beatriz Gomez and Angela Restrepo, CIB, Medellín, Colombia.

They are caused by filamentous fungi (moulds), by yeasts or by fungi that vary between these two forms, depending on environmental conditions (dimorphic fungi; Fig. 13.62).

### Superficial mycoses

Superficial cutaneous fungal infections caused by dermatophyte fungi are described in Chapter 27.

### Candidiasis (thrush)

Superficial candidiasis is caused by *Candida* spp., mainly *C. albicans*. Manifestations include oropharyngeal and vaginal candidiasis ('thrush'), intertrigo and chronic paronychia. Superficial candidiasis often follows antibiotic therapy. Intertrigo is characterised by inflammation in skin folds with surrounding 'satellite lesions'. Chronic paronychia is associated with frequent wetting of the hands. Superficial candidiasis is treated mainly with

topical azoles (p. 121), oral azoles being reserved for refractory or recurrent disease. Severe oropharyngeal and oesophageal candidiasis is seen with T-cell immunodeficiency, including HIV infection, and anti-IL-17 therapy. Recurrent vaginal or penile candidiasis may be a manifestation of diabetes mellitus. Rarely, mutations in the autoimmune regulator gene (*AIRE*) or signal transducer and activator of transcription 1 (*STAT1*) cause a syndrome of chronic mucocutaneous candidiasis, resulting in chronic *Candida* infections of skin, mucosa and nails, with hyperkeratotic nails and erythematous perirungal skin. Patients have cell-mediated immune defects against *Candida* and may have polyendocrinopathy and autoimmune features.

## Subcutaneous mycoses

### Chromoblastomycosis

Chromoblastomycosis is a predominantly tropical or subtropical disease caused by environmental dematiaceous (dark-pigmented) fungi, most commonly *Fonsecaea pedrosoi*. Other causes include *F. compacta*, *Cladophialophora carrionii* and *Phialophora verrucosa*. The disease is a cutaneous/subcutaneous mycosis acquired by traumatic inoculation, particularly the foot, ankle and lower leg. Several months after inoculation, lesions develop. Medical attention is often sought several years later. The initial lesion is a papule. Further papules develop and coalesce to form irregular plaques. Nodular lesions may produce a characteristic 'cauliflower' appearance.

Diagnosis is by histopathological examination of infected material, revealing dematiaceous, rounded, thick-walled 'sclerotic bodies' with septa at right-angles to each other. The aetiological agent is confirmed by culture. Therapeutic approaches include antifungal agents, cryosurgery and surgical excision, alone or in combination, but the optimal therapy is unknown. Itraconazole and terbinafine are the most effective antifungal agents. However, posaconazole has also been used with a good outcome.

### Mycetoma (eumycetoma and actinomycetoma)

Mycetoma is a chronic suppurative infection of the deep soft tissues and bones, notably the limbs but also the abdominal or chest wall or head. It is caused by either filamentous fungi, Eumyces (eumycetoma – 40%) or aerobic Actinomycetes (actinomycetoma – 60%). Many fungi cause eumycetomas, the most common being *Madurella mycetomatis*, *M. grisea*, *Leptosphaeria senegalensis* and *Scedosporium apiospermum*; causes of actinomycetoma include *Nocardia*, *Streptomyces* and *Actinomadura* spp. Both groups produce characteristically coloured 'grains' (microcolonies), the colour depending on the organism (black grains – eumycetoma, red and yellow grains – actinomycetoma, white grains – either). The disease occurs mostly in the tropics and subtropics.

#### Clinical features

The disease is acquired by inoculation (e.g. from a thorn), usually of the foot (Madura foot). A painless swelling at the inoculation site becomes chronic and progressive, spreads steadily within the soft tissues, and eventually penetrates bone. Sub-epidermal nodules mature and rupture, revealing sinuses that may discharge grains. Sinuses heal with scarring, while fresh sinuses appear elsewhere. Deeper tissue invasion and bone involvement are less rapid and extensive in eumycetoma than actinomycetoma. There is little pain and usually no fever or lymphadenopathy, but there is progressive disability.

#### Investigations

Diagnosis of mycetoma involves identification of grains in pus, and/or histopathological examination of tissue. Culture is necessary for species identification and susceptibility testing. Serological tests are not available.

#### Management

Eumycetoma is usually treated with a combination of surgery and antifungal therapy. Antifungal susceptibility testing, if available, is

recommended, although clinical outcome does not necessarily correspond to in vitro test results. Itraconazole and ketoconazole (both 200–400 mg/day) are used most commonly. Success has also been reported with terbinafine monotherapy, and for some cases with liposomal amphotericin B. Refractory cases have responded to voriconazole or posaconazole. Therapy is continued for 6–12 months or longer. In extreme cases, amputation may be required. Actinomycetoma is treated with prolonged antibiotic combinations, most commonly streptomycin and dapsone. Dapsone is replaced by co-trimoxazole with intolerance or refractory disease. Success has also been reported with co-trimoxazole plus amikacin, with rifampicin added in difficult cases and to prevent recurrence.

### Phaeohyphomycosis

Phaeohyphomycoses are a heterogeneous group of fungal diseases caused by a large number (>70) of dematiaceous fungi. In phaeohyphomycosis, the tissue form of the fungus is predominantly mycelial (filamentous), as opposed to eumycetoma (grain) or chromoblastomycosis (sclerotic body). Disease may be superficial, subcutaneous or deep. The most serious manifestation is cerebral phaeohyphomycosis, which presents with a ring-enhancing, space-occupying cerebral lesion. Optimal therapy for this condition is not established but usually includes neurosurgical intervention and antifungal (usually triazole) therapy. Causative agents are *Cladophialophora bantiana*, *Fonsecaea* spp. and *Rhinocladiella mackenziei*, which occurs mainly in the Middle East and is usually fatal.

### Sporotrichosis

Sporotrichosis is caused by *Sporothrix schenckii*, a dimorphic fungal saprophyte of plants in tropical and subtropical regions. Disease is caused by dermal inoculation of the fungus, usually from a thorn (occasionally from a cat scratch). A subcutaneous nodule develops at the site of infection and subsequently ulcerates, with a purulent discharge. The disease may then spread along the cutaneous lymphatic channels, resulting in multiple cutaneous nodules that ulcerate and discharge (lymphocutaneous sporotrichosis). Rarer forms include cutaneous disease presenting with arthritis. Later, draining sinuses may form. Pulmonary sporotrichosis occurs as a result of inhalation of the conidia (spores) and causes chronic cavitory fibronodular disease with haemoptysis and constitutional symptoms. Disseminated disease may occur, especially in immunocompromised hosts

#### Investigations

Typical yeast forms detected on histology confirm diagnosis but are rarely seen; the fungus can also be cultured from biopsy specimens. ELISA detection of antibodies can be helpful.

#### Management

Cutaneous and lymphocutaneous disease is treated with itraconazole (200–400 mg daily, prescribed as the oral solution, which has better bioavailability than the capsule formulation) for 3–6 months. Alternative agents include a saturated solution of potassium iodide (SSKI, given orally), initiated with 5 drops and increased to 40–50 drops 3 times daily, or terbinafine (500 mg twice daily). Localised hyperthermia may be used in pregnancy (to avoid azole use). Osteoarticular disease requires a longer course of therapy (at least 12 months). Severe or life-threatening disease is treated with amphotericin B (lipid formulation preferred).

## Systemic mycoses

### Aspergillosis

Aspergillosis is an opportunistic systemic mycosis, which affects the respiratory tract predominantly. It is described on page 525.

## Candidiasis

Systemic candidiasis is an opportunistic mycosis caused by *Candida* spp. The most common cause is *C. albicans*. Other agents include *C. dubliniensis*, *C. glabrata*, *C. krusei*, *C. parapsilosis* and *C. tropicalis*. *Candida* species identification often predicts susceptibility to fluconazole: *C. krusei* is universally resistant, many *C. glabrata* isolates have reduced susceptibility or are resistant, and other species are mostly susceptible. Candidiasis is usually an endogenous disease that originates from oropharyngeal, genitourinary or skin colonisation, although nosocomial spread occurs. *C. auris* is an emerging species, which has a particular propensity for nosocomial transmission.

### Syndromes of systemic candidiasis

#### Acute disseminated candidiasis

This usually presents as candidaemia (isolation of *Candida* spp. from the blood). The main predisposing factor is the presence of a central venous catheter. Other major factors include recent abdominal surgery, total parenteral nutrition (TPN), recent antimicrobial therapy and localised *Candida* colonisation. Up to 40% of cases will have ophthalmic involvement, with characteristic retinal 'cotton wool' exudates. As this is a sight-threatening condition, all candidaemic patients should have a full ophthalmoscopy review. Skin lesions (non-tender pink/red nodules) may be seen. Although predominantly a disease of intensive care and surgical patients, acute disseminated candidiasis and/or *Candida* endophthalmitis is seen occasionally in injection drug-users, due to candidal contamination of citric acid or lemon juice used to dissolve heroin.

#### Chronic disseminated candidiasis (hepatosplenic candidiasis)

Persistent fever in a neutropenic patient, despite antibacterial therapy and neutrophil recovery, associated with the development of abdominal pain, raised alkaline phosphatase and multiple lesions in abdominal organs (e.g. liver, spleen and/or kidneys) on radiological imaging, suggests a diagnosis of hepatosplenic candidiasis. This represents a form of immune reconstitution syndrome in patients recovering from neutropenia and usually lasts for several months, despite appropriate therapy.

#### Other manifestations

Renal tract candidiasis, osteomyelitis, septic arthritis, peritonitis, meningitis and endocarditis may occur and are usually sequelae of acute disseminated disease. Diagnosis and treatment of these conditions require specialist mycological advice.

### Management

Blood cultures positive for *Candida* spp. must never be ignored. Acute disseminated candidiasis is treated with antifungal therapy, removal of any in-dwelling central venous catheter (whether known to be the source of infection or not) and removal of any documented source. Candidaemia should be treated initially with an echinocandin (p. 122), with subsequent adjustment (usually to intravenous or oral fluconazole) guided by clinical response, species identification and susceptibility testing. Treatment should continue for a minimum of 14 days. Alternative therapies include voriconazole and amphotericin B formulations.

Chronic disseminated candidiasis requires prolonged treatment over several months with fluconazole or other agents, depending on species and clinical response. The duration of the condition may be reduced by adjuvant therapy with systemic glucocorticoids.

## Cryptococcosis

Cryptococcosis is a systemic mycosis caused by two environmental yeast species, *Cr. neoformans* and *Cr. gattii*. *Cr. neoformans* is distributed worldwide and is primarily an opportunistic pathogen, most commonly associated with HIV infection or other immunocompromised hosts. *Cr. gattii* is a primary pathogen with a widespread distribution, including Australasia, Africa, Canada (Vancouver Island) and the north-western USA.

**Fig. 13.63 Cryptococcal disease.** A 23-year-old HIV-positive male developed headache and left-sided weakness. **A** MRI scan of the brain showed a space-occupying lesion (arrow) with surrounding oedema. **B** Histopathological examination of the lesion stained with Grocott's silver stain showed encapsulated yeasts. *Cryptococcus neoformans* was cultured.

Cryptococcosis is acquired by inhalation of yeasts. These may disseminate to any organ, most commonly the CNS and skin. The manifestations of *Cr. neoformans* are most severe in immunocompromised individuals. Conversely, *Cr. gattii* causes severe disease in immunocompetent hosts. Disseminated cryptococcosis (sepsis with cryptococci present in the blood stream or at multiple sites) is largely restricted to immunocompromised patients. CNS manifestations of cryptococcosis include meningitis and cryptococcoma (Fig. 13.63), the latter more likely with *Cr. gattii* infection. Manifestations of pulmonary cryptococcosis range from severe pneumonia (in more immunocompromised patients) to asymptomatic disease with single or multiple pulmonary nodules, sometimes exhibiting cavitation (in patients with lesser immunosuppression). Cryptococcal nodules may mimic other causes of lung pathology, such as tuberculosis or malignancy, and diagnosis requires histopathology and/or culture.

Treatment of severe cryptococcosis is the same as for cryptococcal meningitis, initially with liposomal amphotericin B. Mild pulmonary disease is usually treated with fluconazole, although for asymptomatic nodules resection of the lesions is likely to be sufficient.

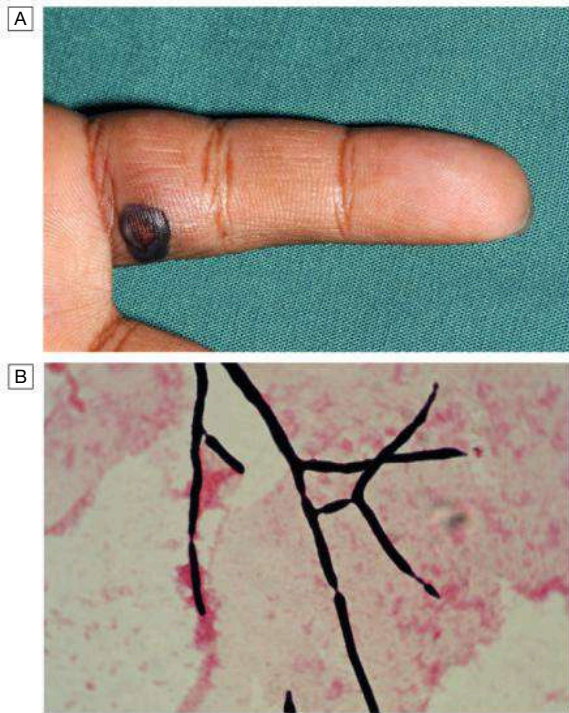

## Fusariosis

*Fusarium* spp. cause disseminated disease in patients with prolonged neutropenia. The disease presents with antibiotic-resistant fever and evidence of dissemination (e.g. skin nodules, endophthalmitis, septic arthritis, pulmonary disease; Fig. 13.64). Unlike *Aspergillus* spp., *Fusarium* spp. are often recovered from blood cultures. Treatment is challenging because of resistance to antifungal agents; voriconazole, posaconazole or lipid-formulated amphotericin B is usually prescribed.

## Mucormycosis

Mucormycosis is a severe but uncommon opportunistic systemic mycosis caused by a number of 'mucoraceous' moulds, most commonly *Lichtheimia* spp., *Rhizomucor* spp., *Mucor* spp. and *Rhizopus* spp. Disease patterns include rhinocerebral/craniofacial, pulmonary, cutaneous and systemic disease. All are characterised by the rapid development

**Fig. 13.64** *Fusarium* infection. A patient presented with fever and skin nodules after developing neutropenia secondary to haematopoietic stem cell transplantation and chemotherapy for relapsed leukaemia. *Fusarium solani* was cultured from skin lesions and blood cultures. **A** Tender, erythematous papules/nodules on upper arm. **B** Gram stain of *Fusarium* in blood culture medium.

of severe tissue necrosis, which is usually fatal if left untreated. The most common predisposing factors are profound immunosuppression from neutropenia and/or haematopoietic stem cell transplantation, uncontrolled diabetes mellitus, iron chelation therapy with desferrioxamine and severe burns. During the COVID-19 pandemic mucormycosis emerged as a specific complication of COVID-19, reported mainly from India.

Definitive diagnosis is by culture but histopathological confirmation is required, as the fungi may be environmental contaminants. Treatment requires a combination of antifungal therapy and surgical débridement, with correction of predisposing factor(s) if possible. High-dose lipid-formulated amphotericin B is most commonly used. Posaconazole is active against many mucoraceous moulds in vitro and may be used as a second-line agent or as oral 'step-down' therapy.

### **Talaromyces marneffeii** infection

*T. marneffeii* is a thermally dimorphic pathogen (filamentous in environmental conditions and yeast at body temperature), which causes disease in South-east Asia, mainly in association with HIV infection (although immunocompetent patients may also be infected). Acquisition is usually by inhalation of environmental spores, with primary lung infection followed by haematogenous dissemination. A generalised papular rash, which progresses to widespread necrosis and ulceration, is a characteristic feature. Skin lesions may resemble molluscum contagiosum. Diagnosis is by histopathology and/or culture of respiratory secretions, blood or any infected clinical material (e.g. skin lesions, bone marrow, biopsies). Treatment involves an amphotericin B formulation followed by itraconazole (in severe infection), or itraconazole alone.

### **Histoplasmosis**

Histoplasmosis is a primary systemic mycosis caused by the dimorphic fungus *Histoplasma capsulatum*. *H. capsulatum* var. *capsulatum* is endemic to east-central USA (especially the Mississippi and Ohio river valleys), parts of Canada, Latin America, the Caribbean, East and

South-east Asia, and Africa. It occurs sporadically in Australia and India, and is very rare in Europe. *H. capsulatum* var. *duboisii* is found in West Africa and Madagascar.

The primary reservoir of *H. capsulatum* is soil enriched by bird and bat droppings, in which the fungus remains viable for many years. Infection is by inhalation of infected dust. Natural infections are found in bats, which represent a secondary reservoir of infection. Histoplasmosis is a specific hazard for explorers of caves and people who clear out bird (including chicken) roosts.

### **Pathology**

The organism is inhaled in the form of conidia or hyphal fragments and transforms to the yeast phase during infection. Conidia or yeasts are phagocytosed by alveolar macrophages and neutrophils, and this may be followed by haematogenous dissemination to any organ. Subsequent development of a T-lymphocyte response brings the infection under control, resulting in a latent state in most exposed individuals.

### **Clinical features**

Disease severity depends on the quantity of spores inhaled and the immune status of the host. In most cases, infection is asymptomatic. Pulmonary symptoms are the most common presentation, with fever, non-productive cough and an influenza-like illness. Erythema nodosum, myalgia and joint pain frequently occur, and chest radiography may reveal a pneumonitis with hilar or mediastinal lymphadenopathy.

Patients with pre-existing lung disease, such as chronic obstructive pulmonary disease (COPD) or emphysema, may develop chronic pulmonary histoplasmosis (CPH). The predominant features of this condition, which mimics tuberculosis, are fever, cough, dyspnoea, weight loss and night sweats. Radiological findings include fibrosis, nodules, cavitation and hilar/mediastinal lymphadenopathy.

Disease caused by *H. capsulatum* var. *duboisii* presents more commonly with papulonodular and ulcerating lesions of the skin and underlying subcutaneous tissue and bone (sometimes referred to as 'African histoplasmosis'). Multiple lesions of the ribs are common and the bones of the limbs may be affected. Lung involvement is relatively rare. Radiological examination may show rounded foci of bone destruction, sometimes associated with abscess formation. Other disease patterns include a visceral form with liver and splenic invasion, and disseminated disease.

Acute disseminated histoplasmosis is seen with immunocompromise, including HIV infection. Features include fever, pancytopenia, hepatosplenomegaly, lymphadenopathy and often a papular skin eruption. Chronic disseminated disease presents with fever, anorexia and weight loss. Cutaneous and mucosal lesions, lymphadenopathy, hepatosplenomegaly and meningitis may develop. *Emergomyces africanus* is a dimorphic fungus described in South Africa, which causes a disseminated histoplasmosis-like illness, mainly associated with HIV infection. Histopathologically, yeast forms appear similar to histoplasmosis and can be distinguished only by PCR.

### **Investigations**

Histoplasmosis should be suspected in endemic areas with every undiagnosed infection in which there are pulmonary signs, enlarged lymph nodes, hepatosplenomegaly or characteristic cutaneous/bony lesions. Radiological examination in long-standing cases may show calcified lesions in the lungs, spleen or other organs. In the more acute phases of the disease, single or multiple soft pulmonary shadows with enlarged tracheobronchial nodes are seen on chest X-ray.

Laboratory diagnosis is by direct detection (histopathology or antigen detection), culture and serology; although antigen detection is the most effective method, it is not widely available. Serology utilises complement fixation testing or immunodiffusion; interpretation is complex and requires a specialist. *Histoplasma* antigen may be detectable in blood or urine. Culture is definitive but slow (up to 12 weeks). Histopathology may show characteristic intracellular yeasts. Diagnosis of subcutaneous or bony infection is mainly by histopathological examination and/or culture.

## Management

Mild pulmonary disease does not require treatment. However, if prolonged, it may be treated with itraconazole. More severe pulmonary disease is treated with an amphotericin B formulation for 2 weeks, followed by itraconazole for 12 weeks, with methylprednisolone added for the first 2 weeks of therapy if there is hypoxia or ARDS. CPH is treated with itraconazole oral solution for 12–24 months, and disseminated histoplasmosis with an amphotericin B formulation followed by itraconazole. Lipid formulations of amphotericin B are preferred but their use is subject to availability. In subcutaneous and bone infection, patterns of remission and relapse are more common than cure. A solitary bony lesion may require local surgical treatment only.

## Coccidioidomycosis

This is a primary systemic mycosis caused by the dimorphic fungi *Coccidioides immitis* and *C. posadasii*, found in the south-western USA and Central and South America. The disease is acquired by inhalation of conidia (arthrospores). In 60% of cases it is asymptomatic but in the remainder it affects the lungs, lymph nodes and skin. Rarely (in approximately 0.5%), it may spread haematogenously to bones, adrenal glands, meninges and other organs, particularly in those with immunocompromise.

Pulmonary coccidioidomycosis has two forms: primary and progressive. If symptomatic, primary coccidioidomycosis presents with cough, fever, chest pain, dyspnoea and (commonly) arthritis and a rash (erythema multiforme). Progressive disease presents with systemic upset (e.g. fever, weight loss, anorexia) and features of lobar pneumonia, and may resemble tuberculosis.

*Coccidioides meningitis* (which may be associated with CSF eosinophils) is the most severe disease manifestation; it is fatal if untreated and requires life-long suppressive therapy with antifungal azoles.

## Investigations and management

Diagnosis is by direct histopathological detection in specimens, culture of infected tissue or fluids, or antibody detection. IgM may be detected after 1–3 weeks of disease by precipitin tests. IgG appears later and is detected with the complement fixation test. Change in IgG titre may be used to monitor clinical progress.

Treatment depends on specific disease manifestations and ranges from regular clinical reassessment without antifungal therapy (in mild pulmonary, asymptomatic cavitory or single nodular disease) to high-dose treatment with an antifungal azole (typically fluconazole), which may be continued indefinitely (e.g. in meningitis). Amphotericin B is

used in diffuse pneumonia, disseminated disease and, intrathecally, in meningitis. Posaconazole has been used successfully in refractory disease.

## Paracoccidioidomycosis

This is a primary systemic mycosis caused by inhalation of the dimorphic fungus *Paracoccidioides brasiliensis*, which is restricted to South America. The disease affects the lungs, mucous membranes (painful destructive ulceration in 50% of cases), skin, lymph nodes and adrenal glands (hypoadrenalism). Diagnosis is by microscopy and culture of lesions, and antibody detection. Oral itraconazole solution (200 mg/day) has demonstrated 98% efficacy and is currently the treatment of choice (mean duration 6 months). Ketoconazole, fluconazole, voriconazole and 2–3-year courses of sulphonamides are alternatives. Amphotericin B is used in severe or refractory disease, followed by an azole or sulphonamide.

## Blastomycosis

*Blastomyces dermatitidis* is a dimorphic fungus endemic to restricted parts of North America, mainly around the Mississippi and Ohio rivers. Very occasionally, it is reported from Africa. The disease usually presents as a chronic pneumonia similar to pulmonary tuberculosis. Bones, skin and the genitourinary tract may also be affected. Diagnosis is by culture of the organism or identification of the characteristic yeast form in a clinical specimen. Antibody detection is rarely helpful. Treatment is with amphotericin B (severe disease) or itraconazole.

## Multiple Choice Questions

13.1. A 35-year-old conservationist returns from an extended stay in Central Africa. They have had recurrent fevers and lymphadenopathy. They failed to respond to a self-administered course of malaria treatment and have been increasingly bothered with headaches. They have also started to note some memory problems. A card agglutination trypanosomiasis test is positive for *Trypanosoma brucei gambiense* and a lymph node aspirate identifies trypanosomes. A lumbar puncture is performed and reveals white blood cells of  $0.7 \times 10^9/L$  and an elevated protein and reduced glucose are noted. Recommended treatment for this condition is with:

- A. Eflornithine
- B. Melarsoprol
- C. Suramin
- D. Nirfurtimox and eflornithine combination therapy
- E. Nirfurtimox

Answer: D.

Nirfurtimox and eflornithine combination therapy (NECT) is now the preferred therapy for *Trypanosoma brucei gambiense* stage 2 infection causing nervous system disease. It should be used when the CSF exam shows  $\geq 0.1 \times 10^9/L$  white blood cells or where a lumbar puncture is indicated but cannot be performed. Melarsoprol was used in the past but treatment was associated with significant mortality while NECT reduces the number of injections and side-effects associated with eflornithine monotherapy which was used before the introduction of NECT. The other agents listed are used for other forms of trypanosomiasis.

13.2. A 35-year-old geologist returns from a 4-week period working in Siberia. Two weeks into his illness he developed fever and myalgia since when he has had low grade symptoms until he developed severe headache and neck stiffness 2 days ago after returning from Siberia. This illness originated approximately after a 3-day field trip when he camped in a wooded area with other colleagues. He has had no skin rash. He is admitted to hospital. Initial lumbar puncture reveals a raised white cell count, primarily lymphocytes and elevated protein. He is placed on ceftriaxone but after 3 days has noted no improvement. Initial investigations include negative Lyme disease serology and negative Lyme disease PCR. An HIV test is also negative. A dengue serology was sent from the accident and emergency room and is reportedly positive. Which of the following is most likely to establish the diagnosis?

- A. Dengue PCR
- B. Follow-up HIV serology
- C. Rocky Mountain spotted fever serology and PCR
- D. Follow-up lumbar puncture for Lyme disease serology in CSF
- E. Tick-borne encephalitis virus serology and PCR

Answer: E.

Tick-borne encephalitis is the most likely cause of this syndrome. After a tick bite the initial illness occurs after a mean of 7 days while emergence of meningitis or encephalitis can take up to a further 28 days. The causative agent is a flavivirus and cross-reactivity with other flavivirus infections, including dengue, is common. Lyme disease is also a consideration but there has been no response to initial therapy. While this remains in the differential, serological testing on CSF is not a standard test. HIV should always be considered but the initial test was negative, although its interpretation relies on knowing when the individual last had

unprotected sexual intercourse. Dengue and Rocky Mountain Spotted Fever infections are not located in the region visited.

13.3. A 74-year-old man with obesity and hypertension presents to the accident and emergency department with fever, loss of smell and respiratory distress in early December 2020. He is up to date on all vaccinations as of November 2020. A D-dimer test is elevated. A CT pulmonary angiogram is performed which shows multiple pulmonary clots. A PCR performed on an upper respiratory sample is positive for a virus. Which virus is most likely to explain this combination of symptoms?

- A. Adenovirus
- B. Cytomegalovirus
- C. Influenza A virus
- D. Respiratory syncytial virus
- E. SARS-CoV-2

Answer: E.

The symptoms are most likely caused by SARS-CoV-2. The development of pulmonary emboli has been particularly reported with COVID-19 though it can occur during many other infections. Although in some seasons the influenza A virus may evolve such that there is reduced vaccine efficacy this only occurs in occasional flu seasons. Other respiratory virus infections would be less likely in this scenario and cytomegalovirus only would be likely if there was a history of very significant T-cell immunosuppression

13.4. A 55-year-old woman is admitted with respiratory distress and an oxygen saturation of 88%. She was previously fit and well, but she works in a care home and recently many of the residents have been sick with COVID-19. An antiviral therapeutic that may have some activity against the causative SARS-CoV-2 is:

- A. Oseltamivir
- B. Remdesivir
- C. Tenofovir
- D. Palivizumab
- E. Tocilizumab

Answer: B.

Remdesivir has antiviral activity against several viruses in vitro and some clinical trials show activity against SARS-CoV-2, although at the time of writing it is not recommended for clinical use by the World Health Organization (WHO). Oseltamivir is used against influenza A, tenofovir against HIV and hepatitis B virus and palivizumab is a monoclonal antibody used against respiratory syncytial virus. Tocilizumab is an anti-IL-6 monoclonal antibody that has shown anti-inflammatory activity in COVID-19, but it is not an antiviral. Tenofovir use in HIV may be associated with lower rates of hospitalisation with COVID-19 but there is no evidence this reflects antiviral activity against SARS-CoV-2.

13.5. A 76-year-old woman with diabetes mellitus is admitted with pyelonephritis and acute kidney injury. She has had multiple previous infections. Despite initial antimicrobial therapy she remains febrile and blood cultures now reveal *Klebsiella pneumoniae* resistant to multiple antimicrobials. The laboratory informs you that the strain is a KPC-2 carbapenemase-producing microorganism with a high meropenem minimum inhibitory concentration (MIC). She has previously been treated for a multidrug-resistant infection with colistin but developed renal impairment and encephalopathy. Subject to supportive sensitivities, which agent would you initially consider switching this patient onto?

- A. Colistin
- B. Ceftazidime-avibactam

- C. Fosfomycin
- D. Meropenem
- E. Tigecycline

Answer: B.

Ceftazidime-avibactam is a beta-lactam/beta-lactamase inhibitor combination that can be used against many multidrug-resistant bacteria, sometimes in combinations. Although avibactam is not active against

some carbapenemases, e.g. New Delhi metallo beta-lactamase, it is active against many, including the *K. pneumoniae*-producing beta-lactamase (KPC-2) enzyme produced here. Although colistin may be required, her previous problems suggest other options should be considered first. Fosfomycin is primarily reserved for uncomplicated urinary tract infections and tigecycline or meropenem, when resistance is not associated with high minimum inhibitory concentrations, are reserved for combination therapy, often with colistin or aminoglycosides.

<span style="font-size: 2em; font-weight: bold; margin-right: 5px;">i</span> HIV clinical staging classifications	
World Health Organization (WHO) clinical stage (used in low- and middle-income countries)	Centers for Disease Control (CDC) clinical categories (used in high-income countries)
<b>Stage 1</b> Asymptomatic Persistent generalised lymphadenopathy	<b>Category A</b> Primary HIV infection Asymptomatic Persistent generalised lymphadenopathy
<b>Stage 2</b> Unexplained moderate weight loss (< 10% of body weight) Recurrent upper respiratory tract infections Herpes zoster Angular cheilitis Recurrent oral ulceration Papular pruritic eruptions Seborrhoeic dermatitis Fungal nail infections	<b>Category B</b> Bacillary angiomatosis Candidiasis, oropharyngeal (thrush) Candidiasis, vulvovaginal; persistent, frequent or poorly responsive to therapy Cervical dysplasia (moderate or severe)/cervical carcinoma in situ Constitutional symptoms, such as fever (38.5°C) or diarrhoea lasting > 1 month Oral hairy leucoplakia Herpes zoster, involving two distinct episodes or more than one dermatome Idiopathic thrombocytopenic purpura Listeriosis Pelvic inflammatory disease, particularly if complicated by tubo-ovarian abscess Peripheral neuropathy
<b>Stage 3</b> Unexplained severe weight loss (> 10% of body weight) Unexplained chronic diarrhoea for > 1 month Unexplained persistent fever (> 37.5°C for > 1 month) Persistent oral candidiasis Oral hairy leucoplakia Pulmonary tuberculosis Severe bacterial infections Acute necrotising ulcerative stomatitis, gingivitis or periodontitis Unexplained anaemia (< 80 g/L), neutropenia (< 0.5 × 10 <sup>9</sup> /L) and/or chronic thrombocytopenia (< 50 × 10 <sup>9</sup> /L)	<b>Category C</b>
<b>Stage 4</b>	Candidiasis of oesophagus, trachea, bronchi or lungs Cervical carcinoma – invasive Cryptococcosis – extrapulmonary Cryptosporidiosis, chronic (> 1 month) Cytomegalovirus disease (outside liver, spleen and nodes) Herpes simplex chronic (> 1 month) ulcers or visceral HIV encephalopathy HIV wasting syndrome Cystoisosporiasis (formerly known as isosporiasis), chronic (> 1 month) Kaposi's sarcoma Lymphoma (cerebral or B-cell non-Hodgkin) Mycobacterial infection, non-tuberculous, extrapulmonary or disseminated Mycosis – disseminated endemic (e.g. coccidioidomycosis, talaromycosis (formerly penicilliosis), histoplasmosis) <i>Pneumocystis</i> pneumonia Pneumonia, recurrent bacterial Progressive multifocal leukoencephalopathy Toxoplasmosis – cerebral Tuberculosis – extrapulmonary (CDC includes pulmonary) Sepsis, recurrent (including non-typhoidal <i>Salmonella</i> ) (CDC only includes <i>Salmonella</i> )  Symptomatic HIV-associated nephropathy* Symptomatic HIV-associated cardiomyopathy* Leishmaniasis, atypical disseminated*
*These conditions are in WHO stage 4 but not in CDC category C.	

## Epidemiology

The acquired immunodeficiency syndrome (AIDS) was first recognised in 1981, although the earliest documented case of HIV infection has been traced to a blood sample from the Democratic Republic of Congo in 1959. AIDS is caused by the human immunodeficiency virus (HIV), which progressively impairs cellular immunity. HIV is a zoonotic infection with simian immunodeficiency viruses (SIV) from African primates, probably first infecting local hunters. SIVs do not cause disease in their natural primate hosts. HIV-1 was transmitted from chimpanzees and HIV-2 from sooty mangabey monkeys. HIV-1 is the cause of the global HIV pandemic, while HIV-2, which causes a similar illness to HIV-1 but progresses more slowly and is less transmissible, is restricted mainly to western Africa. It has been estimated that both HIV-1 and HIV-2 first infected humans about 100 years ago. HIV-2 will not be discussed further in this chapter.

There are three groups of HIV-1, representing three separate transmission events from chimpanzees: M ('major', worldwide distribution), O ('outlier') and N ('non-major and non-outlier'). Groups O and N are restricted to West Africa. Group M consists of nine subtypes: A–D, F–H, J and K, but recombinants of subtypes occur frequently. Globally, subtype C (which predominates in sub-Saharan Africa and India) accounts for half of infections and appears to be more readily transmitted. Subtype B predominates in Western Europe, the Americas and Australia. In Europe, the prevalence of non-B subtypes is increasing because of migration. Subtypes A and D are associated with slower and faster disease progression, respectively.

## Global and regional epidemics

In 2019 it was estimated that there were 38 million people living with HIV (PLWH), 1.7 million new infections and 690 000 AIDS-related deaths. The global epidemiology of HIV has been changed by expanding access to combination antiretroviral therapy (ART), which reached 25.4 million people in 2019: the annual number of AIDS-related deaths has more than halved since the peak in 2004, the number of new infections has decreased by 40% since the peak in 1999, and the number of PLWH has increased. Regions have marked differences in HIV prevalence, incidence and dominant modes of transmission (Box 14.1). HIV has had a devastating impact in sub-Saharan Africa, particularly in southern Africa, where average life expectancy of the general population fell to below 40 years before the introduction of ART.

## Modes of transmission

HIV is transmitted by sexual contact, by exposure to blood (e.g. injection drug use, occupational exposure in health-care workers) and blood products, or to infants of HIV-infected mothers, who may be infected in utero (this is uncommon), perinatally or via breastfeeding. The risk of

contracting HIV after exposure to infected body fluid is dependent on the integrity of the exposed site, the type and volume of fluid, and the level of viraemia in the source person. The approximate transmission risk after exposure is given in Box 14.2. Factors that increase the risk of transmission are listed in Box 14.3.

A high proportion of patients with haemophilia in high-income countries were infected through contaminated blood products before HIV antibody screening was adopted in 1985. Routine screening of blood and blood products for HIV infection has virtually eliminated this mode of transmission. However, because of the lack of adequate screening facilities in resource-poor countries, it has been estimated that 5%–10% of blood transfusions globally are with HIV-infected blood.

## Virology and immunology

HIV is an enveloped ribonucleic acid (RNA) retrovirus from the lentivirus family. After mucosal exposure, HIV is transported via dendritic cells to the lymph nodes, where infection becomes established. This is followed by viraemia and dissemination to lymphoid organs, which are the main sites of viral replication.

Each mature virion has a lipid membrane lined by a matrix protein that is studded with glycoprotein (gp) 120 and gp41 spikes. The inner cone-shaped protein core (p24) houses two copies of the single-stranded RNA genome and viral enzymes. The HIV genome

### 14.2 Risk of HIV transmission after single exposure to an HIV-infected source\*

HIV exposure	Approximate risk
<b>Sexual</b>	
Vaginal intercourse: female to male	0.05%
Vaginal intercourse: male to female	0.1%
Anal intercourse: insertive	0.1%
Anal intercourse: receptive	1.4%
Oral intercourse: insertive	< 0.01%
Oral intercourse: receptive	< 0.01%
<b>Blood exposure</b>	
Blood transfusion	90%
Intravenous drug-users sharing needles	0.67%
Percutaneous needlestick injury	0.3%
Mucous membrane splash	0.09%
<b>Mother to child</b>	
Vaginal delivery	15%
Breastfeeding (per month)	0.5%

\*These are approximate estimates and assume that the source person is not being treated with ART.

### 14.1 Regional HIV prevalence in 2019, incidence trend and dominant mode of transmission

Region	People living with HIV (millions)	HIV incidence trend (2010–2019)	Dominant transmission
Sub-Saharan Africa	25.6	Decreasing	Heterosexual
Asia and Pacific	5.8	Decreasing	MSM, heterosexual
Latin America and Caribbean	2.4	Increasing	MSM, heterosexual
Western and Central Europe, and North America	2.2	Stable	MSM, IDU
Eastern Europe and Central Asia	1.7	Increasing	IDU, MSM
Middle East and North Africa	0.24	Increasing	IDU, MSM

(IDU = injection drug-users; MSM = men who have sex with men)

consists of three characteristic retroviral genes – *gag* (encodes a poly-protein that is processed into structural proteins, including p24), *pol* (codes for the enzymes reverse transcriptase, integrase and protease) and *env* (codes for envelope proteins gp120 and gp41) – as well as six regulatory genes.

HIV infects cells bearing the CD4 receptor; these are T-helper lymphocytes, monocyte-macrophages, dendritic cells, and microglial cells in the central nervous system (CNS). Entry into the cell commences with binding of gp120 to the CD4 receptor (Fig. 14.1), which results in a conformational change in gp120 that permits binding to one of two chemokine co-receptors (CXCR4 or CCR5). The chemokine co-receptor CCR5 is utilised during initial infection, but subsequently the virus may adapt to use CXCR4. Individuals who are homozygous for the CCR5 delta 32 mutation do not express CCR5 on CD4 cells and are immune to HIV infection. Chemokine co-receptor binding is followed by membrane fusion and cellular entry involving gp41. After penetrating the cell and uncoating, a deoxyribonucleic acid (DNA) copy is transcribed from the RNA genome by the reverse transcriptase enzyme, which is carried by the infecting virion. Reverse transcription is an error-prone process and multiple mutations arise with ongoing replication, which results in considerable viral genetic heterogeneity. Viral DNA is transported into the nucleus and integrated within the host cell genome by the integrase enzyme. Integrated virus is known as proviral DNA and persists for the life of the cell. Cells infected with proviral HIV DNA produce new virions only if they undergo cellular activation, resulting in the transcription of viral messenger RNA (mRNA) copies, which are then translated into viral peptide chains. The precursor polyproteins are then cleaved by the viral protease enzyme to form new viral structural proteins and enzymes that migrate to the cell surface and are assembled using the host cellular apparatus to produce infectious viral particles; these bud from the cell surface, incorporating the host cell membrane into the viral envelope. The mature virion then infects other CD4 cells and the process is repeated. CD4 lymphocytes that are replicating HIV have a short survival time of about 1 day. In asymptomatic PLWH it has

Fig. 14.1 Life cycle of HIV. Red arrows indicate sites of action of antiretroviral drugs.

been estimated that more than  $10^{10}$  virions are produced and  $10^9$  CD4 lymphocytes destroyed each day. The CD4 lymphocytes are destroyed primarily by the host immune response rather than by cytopathic effects of HIV.

A small population of T-helper lymphocytes enter a post-integration latent phase. Latently infected cells are important as sanctuary sites from antiretroviral drugs, which act only on replicating virus. Current ART is unable to eradicate HIV infection due to the persistence of proviral DNA in long-lived latent CD4 cells.

The host immune response to HIV infection is both humoral, with the development of antibodies to a wide range of antigens, and cellular, with a dramatic expansion of HIV-specific CD8 cytotoxic T lymphocytes, resulting in a CD8 lymphocytosis and reversal of the usual CD4:CD8 ratio. CD8 cytotoxic T lymphocytes kill activated CD4 cells that are replicating HIV, but not latently infected CD4 cells. HIV evades destruction despite this vigorous immune response, in part because the highly conserved regions of gp120 and gp41 that are necessary for viral attachment and entry are covered by highly variable glycoprotein loops that change over time as a result of mutations selected for by the immune response. The initial peak of viraemia in primary infection settles to a plateau phase of persistent chronic viraemia. With time, there is gradual attrition of the T-helper lymphocyte population and, as these cells are pivotal in orchestrating the immune response, the patient becomes susceptible to opportunistic diseases. The predominant opportunistic infections in PLWH are the consequences of impaired cell-mediated immunity (e.g. mycobacteria, herpesviruses). However, there is also a B-lymphocyte defect with impaired antibody production to new antigens and dysregulated antibody production, with a polyclonal increase in gamma globulins, resulting in an increased risk of infection with encapsulated bacteria, notably *Streptococcus pneumoniae*.

The immune activation in response to HIV infection does not completely resolve on effective ART. This residual inflammatory state has been implicated in the pathogenesis of several non-communicable diseases that occur at a higher rate in PLWH on ART than in the general population; e.g. ischaemic heart disease, thrombotic strokes, chronic kidney disease and non-AIDS cancers.

## Diagnosis and investigations

### Diagnosing HIV infection

Globally, the trend is towards universal HIV testing, rather than testing only those patients at high risk or those with manifestations of HIV infection. However, in the UK, testing is still targeted to high-risk groups (Box 14.4). HIV is diagnosed by detecting host antibodies either with rapid point-of-care tests or in the laboratory, where enzyme-linked immunosorbent assay (ELISA) tests are usually done. Most tests detect antibodies to both HIV-1 and HIV-2. Screening tests often include an assay for p24 antigen in addition to antibodies, in order to detect patients with primary infection before the antibody response occurs. Two positive antibody tests from two different immunoassays are sufficient to confirm infection. Nucleic acid amplification tests (usually polymerase chain reaction, PCR) to detect HIV RNA are used to diagnose infections in infants of HIV-positive mothers, who carry maternal antibodies to HIV for up to 15 months irrespective of whether they are HIV-infected, and to diagnose primary infection before antibodies have developed. PCR is more sensitive than p24 antigen detection for diagnosing primary infection.

The purpose of HIV testing is not simply to identify infected individuals, but also to educate people about prevention and transmission of the virus. Pre- and post-test discussions in the client's home language are essential (Box 14.5). There are major advantages to using rapid point-of-care HIV tests as pre- and post-test discussions can be held at the same visit and ART can be initiated if the HIV infection is confirmed.

A number of baseline investigations should be done at the initial medical evaluation (Box 14.6). The extent of these investigations will depend on the resources available.

## Viral load and CD4 counts

### CD4 counts

CD4 lymphocyte counts are usually determined by flow cytometry but cheaper methods have been developed for low-income countries. The CD4 count is the most clinically useful laboratory indicator of the degree of immune suppression; it is used, together with clinical staging, in decisions to start prophylaxis against opportunistic infections, and is of great value in the differential diagnosis of clinical problems.

The CD4 count varies by up to 20% from day to day and is transiently reduced by intercurrent infections. The normal CD4 count is over 500 cells/mm<sup>3</sup>. The rate of decline in CD4 count is highly variable. People with CD4 counts between 200 and 500 cells/mm<sup>3</sup> have a low risk of developing major opportunistic infections. Morbidity due to inflammatory dermatoses, herpes zoster, oral candidiasis, tuberculosis, bacterial pneumonia and HIV-related immune disorders (e.g. immune thrombocytopenia) becomes increasingly common as CD4 counts decline. Once the count is below 200 cells/mm<sup>3</sup>, there is severe immune suppression and a high risk of AIDS-defining conditions. It is important to note that patients can be asymptomatic despite very low CD4 counts and that major opportunistic diseases occasionally present with high CD4 counts.

### Viral load

The level of viraemia is measured by quantitative PCR of HIV RNA, known as the viral load. Determining the viral load is crucial for monitoring responses to ART (p. 366). People with high viral loads (e.g. >100 000

## 14.4 Patients who should be offered and recommended HIV testing in the UK

### Patients accessing specialist sexual health services (including genitourinary medicine)

- All patients who attend for testing or treatment

### Patients accessing primary care (including emergency care) and secondary care

- All patients attending their first appointment at:
  - Drug dependency programmes
  - Pregnancy termination services
  - Services treating hepatitis B or C, lymphoma or tuberculosis
- All patients who:
  - Have symptoms that may indicate HIV or for which HIV is part of the differential diagnosis
  - Are from a country or group with high rate of HIV infection
  - Are male, or trans women, who have sex with men
  - Report sexual contact with someone from a country with a high rate of HIV infection
  - Disclose high-risk sexual practices, e.g. 'chemsex'
  - Are diagnosed with, or request testing for, a sexually transmitted infection
  - Report a history of injecting drug use
  - Are the sexual partners of people known to be HIV-positive or at high risk of HIV
- In areas of high<sup>1</sup> and extremely high<sup>2</sup> prevalence:
  - All patients not previously diagnosed with HIV who register with a general practice or undergo blood testing for any reason
- In areas of extremely high prevalence<sup>2</sup>:
  - All emergency care and secondary care patients not previously diagnosed with HIV
  - At each general practice consultation consider offering opportunistic HIV testing

### Prison inmates

- All new inmates not previously diagnosed with HIV

<sup>1</sup>Prevalence of diagnosed HIV is 2–5 per 1000 people aged 15–59.

<sup>2</sup>Prevalence of diagnosed HIV is ≥ 5 per 1000 people aged 15–59.

Adapted from National Institute for Health and Care Excellence. *HIV testing: increasing uptake among people who may have undiagnosed HIV*. NICE guideline NG60 (Dec. 2016).

## 14.5 HIV pre- and post-test discussions\*

### Pre-test discussion

- Discuss meaning of positive and negative test results
- Realise importance of maintaining confidentiality
- Identify person to whom positive result could be disclosed
- Explore knowledge and explain natural history of HIV
- Discuss transmission and risk reduction
- Assess coping strategy
- Explain test procedure
- Obtain informed consent

### Post-test discussion

#### Test result negative

- Discuss transmission and need for behaviour modification
- Advise second test 3 months after last exposure

#### Test result positive

- Explain meaning of result
- Organise medical follow-up
- Assess coping strategy
- Stress importance of disclosure
- Explain value of antiretroviral therapy
- Provide written information and useful Internet resources
- Discuss confidentiality issues
- Organise emotional and practical support (names/phone numbers)
- Facilitate notification of sexual partners

\*Current UK guidance is that lengthy pre-test discussion is not required; the basic requirement is that individuals should be made aware that they will be tested for HIV and told how they will receive their result.

## 14.6 Baseline investigations

- CD4 count
- Viral load
- Hepatitis B surface antigen
- Hepatitis C antibody
- Liver function tests
- Full blood count
- Urinalysis, serum creatinine
- Syphilis serology
- Cervical smear in women
- Serum cryptococcal antigen (if CD4 < 100)
- Tuberculin skin test or interferon gamma release assay
- Sexually transmitted infection screen

copies/mL) experience more rapid declines in CD4 count, while those with low viral loads (< 1000 copies/mL) usually have slow or even no decline in CD4 counts. Viral loads are variable; only changes in viral load of more than 0.5 log<sub>10</sub> copies/mL are considered clinically significant.

## Clinical manifestations of HIV

Clinical staging of patients should be done at the initial medical examination, as it provides prognostic information and is a key criterion for initiating prophylaxis against opportunistic infections. Two clinical staging systems are used internationally (p. 351). In both, patients are staged according to the most severe manifestation and do not improve their classification. For example, a patient who is asymptomatic following a major opportunistic disease (AIDS) remains at stage 4 or category C of the WHO and CDC systems respectively, and never reverts to earlier stages. Finally, patients do not always progress steadily through all stages and may present with AIDS, having been asymptomatic.

### Primary HIV infection

Primary infection is symptomatic in more than 50% of cases but the diagnosis is often missed. The incubation period is usually 2–4 weeks after exposure. The duration of symptoms is variable but is seldom longer than 2 weeks. The clinical manifestations (Box 14.7) resemble those of infectious mononucleosis/glandular fever (p. 285), but the presence of maculopapular rash or mucosal ulceration strongly suggests primary HIV infection rather than the other viral causes of

## 14.7 Clinical features of primary infection

- Fever
- Maculopapular rash
- Pharyngitis
- Lymphadenopathy
- Myalgia/arthritis
- Diarrhoea
- Headache
- Oral and genital ulceration
- Meningo-encephalitis
- Bell's palsy

infectious mononucleosis, in which rashes generally occur only if aminopenicillins are given. Atypical lymphocytosis occurs less frequently than in Epstein–Barr (EBV) infection. Transient lymphopenia, including CD4 lymphocytes, is found in most cases (Fig. 14.2), which may result in opportunistic infections, notably oropharyngeal candidiasis. Major opportunistic infections like *Pneumocystis jirovecii* pneumonia (usually referred to as *Pneumocystis* pneumonia, PCP) may rarely occur. Thrombocytopenia and moderate elevation of liver enzymes are commonly present. The differential diagnosis of primary HIV includes acute EBV, primary cytomegalovirus (CMV) infection, rubella, primary toxoplasmosis and secondary syphilis.

Early diagnosis is made by detecting HIV RNA by PCR or p24 antigenaemia. The appearance of specific anti-HIV antibodies in serum (seroconversion) occurs 2–12 weeks after the development of symptoms. The window period, during which antibody tests may be false negative, is prolonged when post-exposure prophylaxis has been used.

### Asymptomatic infection

A prolonged period of clinical latency follows primary infection, during which infected individuals are asymptomatic. Persistent generalised lymphadenopathy with nodes typically < 2 cm diameter is a common finding. Eventually, the lymph nodes regress, with destruction of node architecture as disease advances.

Viraemia peaks during primary infection and then drops as the immune response develops, to reach a plateau about 3 months later. The level of viraemia post seroconversion is a predictor of the rate of decline in CD4 counts, which is highly variable and explained in part by genetic factors affecting the immune response. The median time from infection to the development of AIDS in adults is about 9 years (see Fig. 14.2). A small proportion of untreated PLWH are long-term non-progressors, with CD4 counts remaining in the reference range for 10 years or more. Some long-term non-progressors have undetectable viral loads and are known as 'elite controllers'.

### Minor HIV-associated disorders

A wide range of disorders indicating some impairment of cellular immunity occur in most patients before they develop AIDS (CDC category B or WHO stages 2 and 3). Careful examination of the mouth is important when patients are being followed up, as oral candidiasis and oral hairy leucoplakia are common conditions that require initiation of prophylaxis against opportunistic infections, irrespective of the CD4 count.

### Acquired immunodeficiency syndrome

AIDS is defined by the development of specified opportunistic infections, cancers and severe manifestations of HIV itself (CDC category C or WHO stage 4).

## Presenting problems in HIV infection

HIV itself is associated with a wide variety of clinical manifestations, and opportunistic diseases add many more. All body systems can be affected by HIV. The CD4 count is useful in differential diagnosis (Box 14.8). For example, in a patient with a pulmonary infiltrate and a CD4 count of 350 cells/mm<sup>3</sup>, pulmonary tuberculosis is a likely diagnosis and PCP is very unlikely, but if the patient's CD4 count is 50 cells/mm<sup>3</sup>, both PCP and tuberculosis are likely.

Fig. 14.2 Virological and immunological progression of untreated HIV infection.

Globally, tuberculosis is the most common cause of morbidity and mortality in PLWH. Tuberculosis should be considered in the differential diagnosis of most presenting problems in patients from communities where tuberculosis is common.

### Lymphadenopathy

Persistent generalised lymphadenopathy due to HIV is described above under asymptomatic infection. Lymphadenopathy may also be due to malignancy (Kaposi's sarcoma or lymphoma) or infections, especially tuberculosis, which is an extremely common cause in low- and middle-income countries. Tuberculous lymph nodes are often matted and may become fluctuant due to extensive caseous necrosis; inexperienced clinicians often perform incision and drainage inappropriately when aspiration is all that is required. Symmetrical generalised lymphadenopathy may occur in disseminated tuberculosis. Lymphoma typically presents with large, firm, asymmetric nodes. Rapid enlargement of a node, asymmetric enlargement or lymphadenopathy associated with constitutional symptoms (even if the nodes are symmetrical) warrants further investigation. Lymph node needle aspiration should be performed. One portion of the sample should be sent for *Mycobacterium tuberculosis* PCR, which

has about a 70% yield in tuberculosis (or AAFB microscopy if PCR is unavailable). The other portion should be fixed on a slide and sent for cytology. If caseous liquid is aspirated, this should be sent for mycobacterial culture or PCR. If needle aspiration is unhelpful, or if lymphoma or Kaposi's sarcoma is suspected, excision biopsy should be performed.

### Weight loss

Weight loss is a common finding in advanced HIV infection. The HIV wasting syndrome is an AIDS-defining condition and is defined as weight loss of more than 10% of body weight, plus either unexplained chronic diarrhoea (lasting over 1 month) or chronic weakness and unexplained prolonged fever (lasting over 1 month). This is a diagnosis of exclusion. If the weight loss is rapid (more than 1 kg a month), then major opportunistic infections or cancers become more likely. Painful oral conditions and nausea from drugs contribute by limiting intake. Depression is common and can cause significant weight loss. Measurement of C-reactive protein is helpful in the work-up of weight loss, as this is markedly raised with most opportunistic diseases but not with HIV itself. Erythrocyte sedimentation rate (ESR) is elevated by HIV infection and is therefore not useful as a screen for opportunistic diseases. The presence of fever or diarrhoea is helpful in the differential diagnosis of weight loss (Fig. 14.3).

### Fever

Fever is a common presenting feature. Common causes of prolonged fever with weight loss are listed in Fig. 14.3. Non-typhoid *Salmonella* bacteraemia, which commonly presents with fever in low-income countries, is accompanied by diarrhoea in only about 50% of patients. Pyrexia of unknown origin (PUO) in HIV infection is defined as temperature over 38°C with no cause found after 4 weeks in outpatients or 3 days in inpatients, and initial investigations such as chest X-rays, urinalysis and blood cultures have failed to identify the cause. HIV itself can present with prolonged fever but this is a diagnosis of exclusion, as a treatable cause will be found in most patients. Abdominal imaging, preferably by computed tomography (CT) or magnetic resonance imaging (MRI), should be requested. Abdominal nodes (especially if they are hypodense in the centre) or splenic microabscesses strongly suggest tuberculosis. Mycobacterial blood cultures, which can also detect fungi, should be performed. Bone marrow aspirate and trephine biopsy are helpful if the full blood count shows cytopenias. Liver biopsy may be helpful if the liver enzymes are elevated but is invasive and seldom necessary. Mycobacterial and fungal stains and cultures should be done on all biopsies. Chest X-rays should be repeated after about a week,

as micronodular or interstitial infiltrates may have become apparent (see p. 362 for differential diagnosis).

Tuberculosis is by far the most common cause of PUO in low- and middle-income countries, and in these settings a trial of empirical therapy is warranted after cultures have been sent. In high-income countries, disseminated *Mycobacterium avium* complex (MAC) infection is an important cause of PUO, often also presenting with diarrhoea and splenomegaly. Disseminated endemic mycoses (e.g. histoplasmosis, coccidioidomycosis, talaromycosis) present with PUO, often with papular skin eruptions or mucosal ulcerations (Fig. 14.4). Skin biopsy for histology and fungal culture is often diagnostic.

## Mucocutaneous disease

The skin and mouth must be carefully examined, as mucocutaneous manifestations are extremely common in advanced HIV infection and many prognostically important conditions can be diagnosed by simple inspection. The differential diagnosis of dermatological conditions is simplified by categorising disorders according to the lesion type (Box 14.9). Some common dermatological diseases, notably psoriasis, are exacerbated by HIV. The risk of many drug rashes is increased in PLWH. Skin biopsy should be taken, and sent for histology and culture for mycobacteria and fungi, in patients with papular rashes or if there are constitutional symptoms coinciding with the development of the rash.

## Seborrhoeic dermatitis

Seborrhoeic dermatitis is common in HIV. The severity increases as the CD4 count falls. It presents as scaly red patches, typically in the nasolabial folds and in hairy areas. It is associated with an increased presence of *Malassezia* spp. (dimorphic yeastlike fungi) but the pathogenesis is unknown. It responds well to a combined topical antifungal and glucocorticoid. Selenium sulphide shampoo is helpful for scalp involvement.

## Herpes simplex infections

Recurrences of herpes simplex infection are common and primarily affect the nasolabial and anogenital areas (Fig. 14.5). As immune suppression worsens, the ulcers take longer to heal and become more extensive. Ulcers that persist for more than 4 weeks are AIDS-defining. The

diagnosis is based on clinical appearance and PCR of vesicle fluid or from ulcer swabs, although PCR may need to be reserved to resolve atypical presentations if it is not readily available. Response to a course of antiviral drug such as aciclovir is good but relapses are common. Frequent relapses that persist despite ART should be treated with aciclovir 400 mg twice daily long term (Box 14.10).

## Herpes zoster

Typically presents with a pathognomonic vesicular rash on an erythematous base in a dermatomal distribution (p. 282). The median CD4 count at the first episode of zoster is 350 cells/mm<sup>3</sup>. In patients with

**Fig. 14.4** Disseminated histoplasmosis presenting with diffuse papular rash and fever. Skin biopsy was diagnostic. Courtesy of Professor Graeme Meintjes.

**Fig. 14.3** Presentation and differential diagnosis of weight loss. (ART = antiretroviral therapy; AZT = zidovudine; CMV = cytomegalovirus; d4T = stavudine; KS = Kaposi's sarcoma; MAC = *Mycobacterium avium* complex; NHL = non-Hodgkin lymphoma; PI = protease inhibitor)

## 14.9 Differential diagnosis of skin conditions by lesion type

### Scaly rashes

- Seborrhoeic dermatitis
- Psoriasis\* (exacerbated by HIV)
- Tinea corporis\*
- Dry skin/ichthyosis
- Norwegian scabies\*
- Drug rashes\*

### Pruritic papules

- Pruritic papular eruption ('itchy red bump disease')
- Eosinophilic folliculitis
- Scabies\*

### Papules and nodules (non-pruritic)

- Molluscum contagiosum\*
- Secondary syphilis
- Kaposi's sarcoma
- Bacillary angiomatosis
- Cryptococcosis
- Warts\*
- Disseminated endemic mycoses (histoplasmosis, coccidioidomycosis, talaromycosis and emergomycosis)

### Blisters

- Herpes simplex
- Herpes zoster
- Fixed drug eruptions
- Drug rashes (especially toxic epidermal necrolysis)

### Mucocutaneous ulcers

- Ecthyma
- Herpes simplex
- Aphthous ulcers (minor and major)
- Histoplasmosis
- Drug rashes (Stevens–Johnson syndrome)

### Hyperpigmentation

- Post-inflammatory (especially pruritic papular eruption)
- Zidovudine
- Emtricitabine (palms and soles)

\*See Chapter 27 for more information.

**Fig. 14.5 Severe mucocutaneous herpes simplex.** Chronic anogenital or perioral ulcers are very common in advanced HIV infection.

advanced HIV disease, the rash may be multidermatomal and recurrent episodes may occur. Disseminated zoster is rare. In PLWH, zoster is generally more extensive, has a longer duration and the risk of developing post-herpetic neuralgia is increased. High doses of aciclovir or its congeners should be given for all cases with active disease, irrespective of the time since the onset of the rash. Post-herpetic neuralgia is difficult to manage. Analgesic adjuvants, e.g. amitriptyline and pregabalin, should be commenced in all patients with prolonged pain. Topical capsaicin has modest efficacy.

## Kaposi's sarcoma

Kaposi's sarcoma (KS) is a spindle-cell tumour of lympho-endothelial origin. All forms of KS are due to sexually transmitted human herpesvirus 8, also known as KS-associated herpesvirus. KS occurs in four patterns:

- *classic KS*: rare, indolent and restricted largely to older men of Mediterranean or Jewish origin
- *endemic KS*: occurs in sub-Saharan Africa, is more aggressive, presents at earlier ages than classic KS, and affects men more than women
- *KS in patients on immunosuppressant drugs*: usually transplant recipients, who experience disseminated disease
- *AIDS-associated KS*.

In Africa, the male-to-female ratio of AIDS-associated KS is much lower than is seen with endemic KS, but men are still more affected than women, despite the fact that the seroprevalence of human herpesvirus 8 is the same in both sexes.

AIDS-associated KS is always a multicentric disease. Early mucocutaneous lesions are macular and may be difficult to diagnose. Subsequently, lesions become papular or nodular, and may ulcerate. KS lesions typically have a red–purple colour (Fig. 14.6) but may become hyperpigmented, especially in dark-skinned patients. As the disease progresses, the skin lesions become more numerous and larger. Lymphoedema is common, as lymphatic vessels are infiltrated. KS also commonly spreads to lymph nodes and viscera, especially to the lungs and gastrointestinal tract. Visceral disease occasionally occurs in the absence of mucocutaneous involvement. B symptoms of fever, night sweats and weight loss may occur.

KS may respond to ART. Chemotherapy should be reserved for those patients who fail to respond to ART, or be given together with ART if there are poor prognostic features such as visceral involvement, oedema, ulcerated lesions and B symptoms.

## Bacillary angiomatosis

Bacillary angiomatosis is a bacterial infection caused by *Bartonella henselae* or *B. quintana*. Skin lesions range from solitary superficial red–purple lesions resembling KS or pyogenic granuloma, to multiple subcutaneous nodules or plaques. Lesions are painful and may bleed or ulcerate. The infection may become disseminated with fevers, lymphadenopathy and hepatosplenomegaly. Diagnosis is made by biopsy of a lesion and Warthin–Starry silver staining, which reveals aggregates of bacilli. Treatment with doxycycline or azithromycin is effective.

## Papular pruritic eruption

Papular pruritic eruption ('itchy red bump disease') is an intensely itchy, symmetrical rash affecting the trunk and extremities. It is thought to be due to an allergic reaction to insect bites. In sub-Saharan Africa, it is the most common skin manifestation of advanced HIV disease. Post-inflammatory hyperpigmentation is common. Topical glucocorticoids, emollients and antihistamines are useful but response is variable. Measures to reduce insect bites are logical but difficult to implement in low-income settings.

## Drug rashes

Cutaneous hypersensitivity to drugs occurs about 100 times more frequently in HIV infection. The most common type is an erythematous maculopapular rash, which may be scaly. The drugs most commonly associated with rashes are sulphonamides and non-nucleoside reverse transcriptase inhibitors (NNRTIs – see below). Severe, life-threatening features of drug rashes include blistering (when this affects more than 30% of surface area it is known as toxic epidermal necrolysis), involvement of mucous membranes (Stevens–Johnson syndrome), or systemic involvement with fever or organ dysfunction (especially hepatitis, which is often delayed for a week or two after the rash develops). Because sulphonamides are important in the treatment and prophylaxis of opportunistic infections, rechallenge or desensitisation is often attempted in patients who have previously experienced rashes, provided the reaction was not life-threatening. Details of rashes caused by ART are given below.

## 14.10 Treatment of common opportunistic infections in adults with AIDS

Opportunistic infection	Treatment	Alternative treatment	Secondary prophylaxis <sup>1</sup>
<i>Pneumocystis jirovecii</i> pneumonia	Co-trimoxazole 20/100 mg/kg/day IV/PO (in 4 divided doses) for 21 days; maximum per dose 320/1600 mg Early adjunctive prednisone 40 mg twice daily, if hypoxic	Clindamycin 900 mg 3 times daily IV (switch to 600 mg 3 times daily PO once improving) plus primaquine 30 mg PO daily for 21 days	Co-trimoxazole 160/800 mg daily PO
Cerebral toxoplasmosis	Sulfadiazine 15 mg/kg 4 times daily PO plus pyrimethamine 200 mg stat PO, then 75 mg daily plus folinic acid 15–25 mg daily for 6 weeks	Co-trimoxazole 320/1600 mg twice daily IV/PO for 4 weeks, then 160/800 mg twice daily for 3 months	Co-trimoxazole 160/800 mg daily PO
Cryptococcosis	Liposomal amphotericin B 4 mg/kg/day IV plus flucytosine 25 mg/kg 4 times daily PO for 7 days, followed by fluconazole 400 mg daily PO for 8 weeks	Amphotericin B 1 mg/kg/day IV plus fluconazole <sup>2</sup> 800 mg daily IV/PO for 14 days, followed by fluconazole 400 mg daily PO for 8 weeks	Fluconazole 200 mg daily PO (for minimum of 1 year)
Oesophageal candidiasis	Fluconazole 200 mg daily IV/PO for 14 days	Itraconazole 200 mg daily PO for 14–21 days	Not usually recommended
Disseminated <i>Mycobacterium avium</i> complex	Clarithromycin 500 mg twice daily PO plus ethambutol 15 mg/kg daily PO	Azithromycin 500 mg daily PO plus ethambutol 15 mg/kg daily PO	Continue treatment for minimum of 1 year
Herpes simplex ulcers	Aciclovir 400 mg 3 times daily PO for 5–10 days	Valaciclovir 500 mg or famciclovir 125 mg twice daily PO for 5–10 days	Aciclovir 400 mg twice daily PO if recurrences are frequent/severe
<i>Cystoisospora belli</i> diarrhoea	Co-trimoxazole 160/800 mg 4 times daily PO for 10 days	Ciprofloxacin 500 mg twice daily PO for 10 days	Co-trimoxazole 160/800 mg daily PO

<sup>1</sup>Secondary prophylaxis may be discontinued once CD4 counts have increased to >200 cells/mm<sup>3</sup> on antiretroviral therapy for at least 3 months. <sup>2</sup>Only if flucytosine is unavailable. (IV = intravenous; PO = orally)

### Oral conditions

Oropharyngeal candidiasis is common in advanced HIV infection. It is nearly always caused by *Candida albicans*, but azole-resistant *Candida* species may be selected for if there have been repeated courses of azole drugs. Pseudomembranous candidiasis is the most common manifestation, with white patches on the buccal mucosa (p. 350) that can be scraped off to reveal a red raw surface. Erythematous candidiasis is more difficult to diagnose and presents with a reddened mucosa and a smooth shiny tongue. Angular cheilitis due to *Candida* is a common manifestation. Topical antifungals are usually effective. Antifungal lozenges are more effective than antifungal solutions. Systemic azole therapy, usually fluconazole, should be given if topical therapy fails or if there are oesophageal symptoms.

Oral hairy leucoplakia (p. 350) appears as corrugated white plaques running vertically on the side of the tongue and is virtually pathognomonic of HIV disease. It is usually asymptomatic and is due to EBV.

Herpetiform oral ulcers occur in primary infection. Herpes simplex typically affects the nasolabial area but may cause oral ulcers. In early disease, minor aphthous ulcers are common. In advanced disease, giant aphthous ulcers occur. These destroy tissue, are painful and need to be differentiated from herpes simplex and CMV ulcers by biopsy. They respond to systemic glucocorticoids and ART. Some disseminated endemic mycoses, notably histoplasmosis (p. 346), may cause oral ulcers, usually associated with constitutional symptoms. Finally, superficial oral ulcers may occur as part of the Stevens–Johnson syndrome, usually caused by sulphonamides or NNRTIs.

KS often involves the mouth, especially the hard palate (see above and Fig. 14.6). Nodular oral lesions are associated with a worse prognosis.

Gingivitis is common in advanced HIV infection. Acute necrotising ulcerative gingivitis and periostitis (p. 350) can result in loss of teeth.

### Nail disorders

Fungal infections of the nails (onychomycosis) are common and often involve multiple nails. Blue–black discoloration of nails may be due to HIV or to the antiretroviral drug zidovudine.

**Fig. 14.6 Oral Kaposi's sarcoma.** A full examination is important to detect disease that may affect the palate, gums, fauces or tongue.

## Gastrointestinal disease

### Oesophageal diseases

Oesophageal candidiasis (Fig. 14.7) is the most common cause of pain on swallowing (odynophagia), dysphagia and regurgitation in advanced HIV infection. Concomitant oral candidiasis is present in most patients. Systemic azole therapy, e.g. fluconazole 200 mg daily for 14 days, is usually effective but relapses are common (see Box 14.10). Patients whose oesophageal symptoms fail to respond to azoles should be investigated with oesophagoscopy; major aphthous ulceration and CMV ulcers are the most likely causes and need to be differentiated by biopsy.

### Diarrhoea

Chronic diarrhoea is a common presenting problem in patients with advanced HIV, especially in areas where there is no access to safe water. It is a component of the HIV wasting syndrome. The differential diagnosis

**Fig. 14.7 Oesophageal candidiasis.** Endoscopy showing typical pseudomembranous candidiasis.

of diarrhoea depends on whether the presentation is with large or small bowel symptoms (see Fig. 14.3).

### Large bowel diarrhoea

Acute diarrhoea caused by the bacterial enteric pathogens *Campylobacter*, *Shigella* and *Salmonella* occurs more frequently than in HIV-negative people and the illness is more severe. Bacteraemia is more common, notably due to non-typhoid *Salmonella*. Diarrhoea caused by *Clostridioides difficile* should be considered if there has been prior exposure to antibiotics, as is often the case in patients with symptomatic HIV.

CMV colitis presents with chronic large bowel symptoms and fever in patients with CD4 counts below 100 cells/mm<sup>3</sup>. On colonoscopy, ulcers are seen, mostly involving the left side of the colon. Biopsy of ulcers shows typical 'owl's-eye' inclusion bodies.

### Small bowel diarrhoea

Chronic small bowel diarrhoea may be due to HIV enteropathy, which is a diagnosis of exclusion. It typically presents with chronic watery diarrhoea and wasting without fever. Infection with one of three unicellular organisms is responsible for most cases: cryptosporidiosis, microsporidiosis and cystoisosporiasis (formerly known as isosporiasis) (Box 14.11). All three organisms are intracellular parasites that invade enterocytes. If the diagnosis is not made by stool microscopy on at least two specimens, a duodenal biopsy should be performed (Fig. 14.8).

About 40% of patients with disseminated MAC infections have watery diarrhoea. Fever is a prominent feature of MAC infection, which helps differentiate it from cryptosporidiosis, microsporidiosis and cystoisosporiasis. Intestinal tuberculosis typically involves the ileocaecal area and may present with fever, weight loss and diarrhoea, but the diarrhoea is seldom profuse.

## Hepatobiliary disease

### Chronic viral hepatitis

Hepatitis B and/or C (HBV and HCV) co-infection is common in PLWH due to shared risk factors for transmission. The natural history of both HBV and HCV is altered by HIV co-infection. In the ART era, chronic liver disease from viral hepatitis has emerged as a major cause of morbidity and mortality. HBV and HCV are further described in Chapter 24.

### Hepatitis B

HBV infection is common in several groups of people at risk of HIV infection: residents of low- and middle-income countries, injection drug-users, people with haemophilia and men who have sex with men (MSM). HBV status should be checked at baseline in all PLWH. HIV co-infection increases HBV viraemia, is associated with less elevation of transaminase, and increases the risk of liver fibrosis and hepatocellular

## 14.11 Common causes of chronic watery diarrhoea

	Cryptosporidiosis	Microsporidiosis	Cystoisosporiasis
<b>Organism</b>	Protozoan	Fungus	Protozoan
<b>Species</b>	<i>Cryptosporidium parvum</i> <i>C. hominis</i>	<i>Enterozoon bienewsi</i> <i>Encephalitozoon intestinalis</i> etc.	<i>Cystoisospora belli</i>
<b>Animal host</b>	Multiple	Multiple	No
<b>Distribution</b>	Global	Global	Tropics
<b>Stool examination</b>	Acid-fast stain	Trichrome stain Polymerase chain reaction	Acid-fast stain
<b>Specific treatment</b>	No established therapy	Albendazole (some species)	Co-trimoxazole

**Fig. 14.8 Cryptosporidiosis.** Duodenal biopsy may be necessary to confirm cryptosporidiosis or microsporidiosis. The arrow indicates an oocyst.

carcinoma. All patients with HBV infection should be treated with ART, including the nucleotide reverse transcriptase inhibitor (NRTI) tenofovir, which is also effective for HBV. A flare of hepatitis may be associated with improved immune function after starting ART or discontinuing antiretrovirals that have anti-HBV activity. HBV co-infection increases the risk of antiretroviral hepatotoxicity.

### Hepatitis C

HCV infection is common in injection drug-users and people with haemophilia. HIV co-infection increases HCV viraemia and increases the risk of liver fibrosis and hepatocellular carcinoma. Treatment for HCV should be commenced together with ART. As with HBV co-infection, a flare of hepatitis may be associated with improved immune function after starting ART, and there is an increased risk of antiretroviral hepatotoxicity. Response to anti-HCV therapy is similar to that seen in HIV-negative people.

### HIV cholangiopathy

HIV cholangiopathy, a form of secondary sclerosing cholangitis, may occur in patients with severe immune suppression. Papillary stenosis is common and is amenable to cauterization via endoscopic retrograde cholangiopancreatography (ERCP), which provides symptomatic relief. Acalculous cholecystitis is a common complication of cholangiopathy. ART may improve the condition.

## Respiratory disease

Pulmonary disease is common and is the major reason for hospital admission in advanced HIV disease. Influenza and COVID-19 are more

severe in PLWH. Most patients who are admitted for respiratory diseases will have either bacterial pneumonia, pulmonary tuberculosis or PCP. PCP is more common in high-income countries, while tuberculosis is more common in low- and middle-income countries. An approach to the differential diagnosis of all three conditions is given in Box 14.12.

### ***Pneumocystis jirovecii* pneumonia (Pneumocystis pneumonia, PCP)**

The key presenting feature of PCP is progressive dyspnoea with a duration of less than 12 weeks. Dry cough and fever are common. The chest X-ray typically shows a bilateral interstitial infiltrate spreading out from the hilar regions (Fig. 14.9) but may be normal initially. High-resolution CT scan is more sensitive than chest X-ray, usually showing typical 'ground-glass' interstitial infiltrates. Pneumatoceles may occur and may rupture, resulting in a pneumothorax. The diagnosis is made with silver stains, PCR or immunofluorescence of broncho-alveolar lavage or induced sputum (note that spontaneously produced sputum should not be sent, as the yield is low). Treatment is with high-dose co-trimoxazole, together with adjunctive systemic glucocorticoids if the patient is hypoxic (see Box 14.10).

### **Pulmonary tuberculosis**

Tuberculosis is the most common cause of admission in countries with a high tuberculosis incidence. Pulmonary tuberculosis in patients with mild immune suppression typically presents as in HIV-uninfected patients, with a chronic illness and apical pulmonary cavities (p. 518). However, in patients with CD4 counts below 200 cells/mm<sup>3</sup>, there are four important differences in the clinical presentation of pulmonary tuberculosis:

- Tuberculosis progresses more rapidly, with a subacute or even acute presentation. The diagnosis therefore needs to be made and therapy commenced promptly. A trial of empirical therapy is often justified while awaiting the results of mycobacterial cultures.
- The chest X-ray appearance alters: cavities are rarely seen, pulmonary infiltrates are no longer predominantly in apical areas, and pleural effusions and hilar or mediastinal lymphadenopathy are common (Fig. 14.10). A normal chest X-ray is not unusual in symptomatic patients with tuberculosis confirmed on sputum culture. These atypical findings can result in a delayed or missed diagnosis.
- Sputum smears, which are positive in most HIV-uninfected adults with pulmonary tuberculosis, are negative in more than half of patients. The main reason for this is the absence of pulmonary cavities.
- Many patients have disseminated tuberculosis, sometimes with a classic miliary pattern on chest X-ray, but more commonly

presenting with atypical pulmonary infiltrates together with extrapulmonary tuberculosis. The most common sites of concomitant extrapulmonary tuberculosis are the pleura and lymph nodes. A rapid diagnosis can be made with the urine lipoarabinomannan lateral flow assay.

Tuberculosis in PLWH responds well to standard short-course therapy (p. 522).

### **Bacterial pneumonia**

The incidence of bacterial pneumonia is increased about 100-fold by HIV infection. The severity, likelihood of bacteraemia, risk of recurrent pneumonia and mortality are all increased compared with HIV-negative patients. The aetiology is similar to that of community-acquired pneumonia in HIV-uninfected patients with comorbidity: *S. pneumoniae*

**Fig. 14.9** *Pneumocystis* pneumonia: typical chest X-ray appearance. Note the interstitial bilateral infiltrate.

**Fig. 14.10** Chest X-ray of pulmonary tuberculosis in advanced HIV infection. Lower-zone infiltrates and hilar or mediastinal nodes in a patient with a CD4 count of <200 cells/mm<sup>3</sup>.

#### **14.12 Comparative features of bacterial pneumonia, *Pneumocystis jirovecii* pneumonia and pulmonary tuberculosis**

	Bacterial pneumonia	<i>Pneumocystis jirovecii</i> pneumonia (PCP)	Pulmonary tuberculosis
<b>Duration</b>	Acute	Subacute	Variable
<b>Dyspnoea</b>	Common	Prominent	Occasional
<b>White cell count</b>	Increased	Normal	Normal/low
<b>Chest X-ray</b>			
<b>Infiltrate</b>	Consolidation	Interstitial	Nodular
<b>Bilateral infiltrate</b>	Occasional	Usual	Common
<b>Effusion</b>	Occasional	No	Common
<b>Nodes</b>	Rare	No	Common

is the most common cause, followed by *Haemophilus influenzae*, Enterobacteriales (e.g. *Klebsiella pneumoniae*) and *Staphylococcus aureus*. The prevalence of atypical bacteria in PLWH with pneumonia is similar to that in the general population. Treatment is with a broad-spectrum  $\beta$ -lactam (e.g. ceftriaxone, amoxicillin–clavulanate), with the addition of a macrolide if the pneumonia is severe).

Uncommon bacteria causing pneumonia include *Pseudomonas aeruginosa*, *Nocardia* (which mimics tuberculosis) and *Rhodococcus equi* (which can cause pulmonary cavities).

### Miscellaneous causes of pulmonary infiltrates

Pulmonary cryptococcosis may present as a component of disseminated disease or be limited to the lungs. The chest X-ray appearances are variable. Cryptococcomas occur less commonly than in HIV-uninfected people. The most common radiographic pattern seen in HIV infection is patchy consolidation, often with small areas of cavitation resembling tuberculosis. Pleural involvement is rare. The disseminated endemic mycoses (histoplasmosis, coccidioidomycosis, emeryngomycosis and talaromycosis) often cause diffuse pulmonary infiltrates, mimicking miliary tuberculosis.

Lymphoid interstitial pneumonitis is a slowly progressive disorder causing a diffuse reticulonodular infiltrate. It is caused by a benign polyclonal lymphocytic interstitial infiltrate and is part of the diffuse infiltrative lymphocytosis syndrome (DILS), described later in this chapter. Patients may have other features of DILS, notably parotidomegaly.

KS often spreads to the lungs. Typical chest X-ray appearances are large, irregular nodules, linear reticular patterns and pleural effusions. Bronchoscopy is diagnostic.

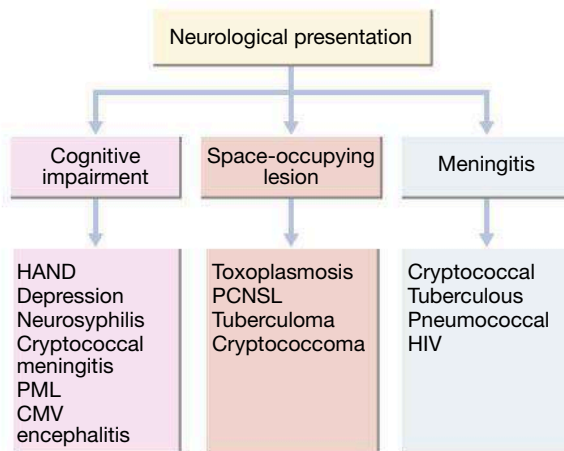

### Nervous system and eye disease

The central and peripheral nervous systems are commonly involved in HIV, either as a direct consequence of HIV infection or due to opportunistic diseases. An approach to common presentations is outlined in Fig. 14.11.

### Cognitive impairment

#### HIV-associated neurocognitive disorders

HIV is a neurotropic virus and invades the CNS early during infection. Meningoencephalitis may occur at seroconversion. PLWH often have abnormalities on neuropsychiatric testing. The term HIV-associated neurocognitive disorder (HAND) describes a spectrum of disorders:

**Fig. 14.11** Presentation and differential diagnosis of HIV-related neurological disorders. (CMV = cytomegalovirus; HAND = HIV-associated neurocognitive disorder; PCNSL = primary CNS lymphoma; PML = progressive multifocal leucoencephalopathy)
